All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Edwin James Hopgood, Northampton.—*Portrait of Amos Jinks.*

James Downey & Sons, South Shields.—*Portrait of Mr. Emmanuel Lasker.*

John Ellis, Nottingham.—*Portrait of William Thompson, alias Bendigo, with trophies.*

Isaac Slater, Llandudno.—*Photograph of a group of the Right Hon. W. E. Gladstone and party taken at the Chalet, Beddgelert. Mr. Gladstone addressing the mass meeting at Cumllan, Snowdon, on September 13, 1892. Mr. Gladstone and party at the Chalet, Beddgelert. Mr. W. J. Williams conducting Welsh Choir at the mass meeting, Cumllan, Snowdon, on the occasion of Mr. Gladstone's Visit.*

A. JACKSON.—Study *Photographic Chemistry*, by Hardwich & Taylor.

A. J.—Yes; a ten-grain solution means ten grains of gelatine to one ounce of water.

F. HAMILTON.—Mr. Redmond Barrett's work has not been reproduced in book form.

R. WATKINS.—If the pyroxyline yields a crapy film when dissolved in strong ether and alcohol, it is not at all adapted for bromide emulsion, or, indeed, any photographic purpose.

F. G. PACKER.—1. We do not know the address of any other makers of dry collodion plates than that of the firm named. 2. Yes. 3. Mr. H. P. Robinson's work on *The Studio, and what to do in it.*

NESTOR.—Unless the paper is more highly salted than most albumenised papers now are, no advantage will be gained by increasing the strength of the sensitising beyond that you are now using. The increased cost would not be met by a compensating advantage.

R. W. (Yorks).—Too late now. The Exhibition opened on Monday last. Examples of the new process will prove interesting, if shown at the ordinary meeting of the different societies. It will by this means gain a certain amount of publicity, which we presume is your chief object.

W. D. B. asks: "Can enlargements be made by the electric arc light on carbon, platinum, or the new printing-out chloride paper? If so, what candle power would be required?"—The thing is quite possible, but a very powerful light and a long exposure would be required which would make the method impracticable, on account of the cost, for commercial purposes. If enlargements by the processes are required, the best way is to make enlarged negatives and print from them in the ordinary way.

ALF. DOWNES.—It must not be assumed, at the present time, because methylated spirit becomes "milky" on the addition of water, that it contains resins, or is what is known as "finish." Under a recent regulation all methylated spirit sold in small quantities must contain a certain proportion of mineral naphtha, and this in itself, on the addition of water, will cause turbidity. If the article was obtained from one who is licensed to sell methylated spirit, the probability is that it is free from resins.

R. E. COLE writes: "In working with the hand camera I always use the quickest plates I can get, and have tried all the best brands. My complaint is that with all of them the image is so coarse and granular. When I use ordinary plates, even of the same brands, it is always very different, being fine and delicate. Must one always have a coarse image if highly sensitive plates are used?"—Highly sensitive plates, as a rule, give a much coarser image than slow ones, though some makes, with equal rapidity, give a finer deposit than others.

W. SAYER says: "I have put up a small studio in my garden for figure studies, but while at work I am greatly annoyed by the children next door staring in and laughing at the models. I have painted over the glass so that they cannot see through, but that seems to stop out too much light. Is there any medium, other than ground glass, that will admit all the light, and yet cannot be seen through?"—If the studio, or such portions of it as are exposed to the annoyance, be glazed with transparent fluted glass, there will be no loss of light, and nothing can be distinguished through it from the outside.

D. DUMERY write: "Herewith part of 12×10 print which, after examination, you will find full of spots, trusting to your superior knowledge to find out the cause, for I have never met with such in all my fifteen years' experience. The paper we have been using these last three weeks is Saxe of the finest make. The toning bath is the ordinary chloride and acetate, and the sensitising bath is fifty grains, fixing and washing the same as we have done these seven years. On returning from my holiday, the printer called my attention to these spots, and told me that they had made their appearance gradually. I at once had dishes, trays, tanks, and washing machine well cleaned, and we have been free from them for five days, when they made their appearance again this morning, spoiling fifty or more prints, all sizes. You will find a piece of the paper ready-sensitised and the part of the finished print."—The spots appear to be due to particles of foreign matter coming in contact with the surface of the paper at the time of sensitising or while it is drying, and reducing the silver to the metallic state. They are not in the paper itself or they would show on the back, which is not the case. Particles of foreign matter, in the form of dust, are constantly present in all work-rooms which are not kept scrupulously clean, that would cause spots similar to the ones complained of.

S. A. E.—The flat appearance of the portraits is due to the models being illuminated with a direct front light, so that there are no shadows to give rotundity to the pictures. Stop off the direct front light, and illuminate the sitters from one side, softening the cast shadows, if necessary, with reflectors.

LANTERN SOCIETY.—First Meeting of the season, Monday, October 10 The slides, *Going to America*, will be shown.

HACKNEY PHOTOGRAPHIC SOCIETY.—The arrangements for October are:—October 4, Open Night. Bring apparatus and work. 11, Members' Lantern Night. 18, *Photography without Studio*, Mr. S. H. Barton. 25, *Flashtight Photography*, Mr. R. Beckett.

IN the course of his able practical discourse on *Retouching* before the North London Photographic Society, on Tuesday week, Mr. Redmond Barrett drew attention to the qualities of Messrs. L. & C. Hardtmuth's retouching pencils, of which he spoke highly for the purpose.

*** OWING to pressure of Exhibition matter this week, we are obliged to hold over "Stereoscopic Photography" (G. A. Thomason), "A Reminiscence" (Valentine Blanchard), and other articles, together with several answers to correspondents, &c. These in our next.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—October 1, "Winding up" Outing to Hampstead, "Bull and Bush," half-past three. 6, *Various Printing Processes*, by Mr. B. Foulkes Winks. 13, *Practical Demonstration on Retouching*, by Mr. Redmond Barrett. 29, First Lantern Night, and Competition Slides.

PHOTOGRAPHIC CLUB.—October 5, Exhibition of Slides from Negatives taken at the Edinburgh Convention, and report of the delegates. 12, Members' Open Night. Saturday next, October 1, Last Outing of the season, Hampstead Heath. Meet at the Flagstaff at two, group at "Bull and Bush" at four, tea at half-past five.

WE have had submitted for our inspection some ivory miniatures, together with other portraits, painted by Miss Miriam Twyman, of 3, North-villas, N.W., both from photographs and life, one—an exhibition picture of the late Duke of Clarence—being a most pleasing likeness of the young Prince. All the pictures are of remarkable elegance and finish.

STATUARY PHOTOGRAPHS.—A few weeks ago we published the specification of a patent obtained by Messrs. Bradshaw & Co., of Altrincham, for combining the head of a living subject with a statuary bust. Several examples of Messrs. Bradshaw's work have since been submitted to us. The junction of the head with the bust, of the living with the dead, is effected in a most admirable manner, and some excellent effects have been produced.

WE alluded some weeks ago to the opening of a series of limelight lectures, inaugurated by the Glasgow Institute of the Fine Arts. These were instituted in response to a very general demand last year for such entertainments, and we are glad to say that they have been very successful. On Thursday, September 22, Mr. George Mason gave his lecture in this series on *Mary Queen of Scotts—her Palaces and Prisons*, which was well received by a large and enthusiastic audience. The subject was well handled, and peculiarly suited to a Scotch audience. The larger proportion of the pictures were taken by Mr. Mason at the various places represented, which gave them an enhanced value.

IN last week's JOURNAL, in our *Run Through some of the Scotch Studios*, a rather strange printer's error, in the description of Mr. John Fergus's place, occurred. We are made to say that he opened a business "in cameras," when it should have been in Cannes. Can anything be funnier than to suppose Mr. Fergus had turned cabinet-maker? We hasten, however, to put the matter right, although we have no doubt that the cause of error, and what was really meant, would be seen at once by the general reader, who is familiar with the facts that all the world knows. And in the Swan Watson article we say he built the studios. Now, we find this is a mistake on our part. The studios were built by Mr. Shaw, and, on his retirement, bought by Mr. Watson.

As previously announced, we propose, during the months of October, November, December, January, February, and March, issuing with THE BRITISH JOURNAL OF PHOTOGRAPHY *a gratis supplement, devoted to the interests of the makers and users of the optical lantern and its numerous applications. The first supplement will appear with the* JOURNAL *of Friday, October 7 next. The growth in utility and popularity of the optical lantern, its increasing importance as an adjunct to amateur photography, its manifold advantages to the photographer, the scientific investigator, the lecturer, and many others, more than justify the institution of a special department of* THE BRITISH JOURNAL OF PHOTOGRAPHY *in which the topic in all its phases can be exclusively treated, besides rendering the interests of the many commercial firms now engaged in the manufacture of lanterns and their many accessories so considerable as equally to demand increased facilities for their separate representation.*

CONTENTS.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1692. Vol. XXXIX.—OCTOBER 7, 1892.

The Almanac for 1893 is already in course of preparation, and we shall be happy to receive short contributions on practical subjects from those who in former years have enriched its pages with the results of their experience and practice in the photographic art. Not less cordially also do we invite the newer supporters of The British Journal of Photography and its Almanac to include themselves among the contributors to the Annual which for many years past has been highly esteemed for the valuable writings of numerous able photographic workers.

As we were compelled last year to omit several interesting articles from the Almanac on account of the late dates at which they were received, we should be glad if intending contributors would endeavour to send us their articles *as early as possible.*

Secretaries of Societies, and particularly of those established since the appearance of the last Almanac, would, if they have not already done so, oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies in order that the list may be made as complete as possible.

The Publishers desire us to inform intending advertisers that the announcement pages of the Almanac are rapidly filling up, and that in order to avoid disappointment it is essential that copy and orders for advertisements be transmitted to them without delay.

REVERSED NEGATIVES.

The phenomenon of reversal forms the theme of many speculations, and is even understood to such an extent as to be producible at will. Yet so far, although the latter circumstance distinctly raises the inference that it is capable of practical application in the production of reversed negatives, but little advantage appears to have been taken of it. This is all the more remarkable when we consider the many occasions on which negatives reversed as regards left and right are required for photo-mechanical printing purposes. Again, for the duplication of negatives and positives there are possibly features in the method which entitle it to consideration.

By a communication from a correspondent in our last number, nevertheless, we gather that at least in one instance reversed negatives at one operation are successfully obtained by the solarisation method, and from the particulars which that gentleman, Mr. E. Frewing, gives of his mode of procedure, we conceive that we are justified in once more drawing attention to its practical possibilities.

As in every other contact reproduction process when first submitted to trial, the uncertainties attendant upon the exposure, which varies with the character of the negative, the rapidity and other qualities of the plate, and the actinic force of the light, interpose difficulties which only some experience and consideration enables one to surmount. That experience, however, is not, as we have said, difficult to acquire with a little care and assiduity in paying regard to the conditions above described.

The real difficulty of this method—at least, in our experience—has been that of the development of the pictures. So far as we can recollect, in all published accounts of experiments, and certainly in our own attempts, the developer employed has usually been alkaline pyrogallol or hydroquinone. But these developers, we have more than once satisfied ourselves, are far too powerful for the development of solarised negatives or positives, the half-tones of the picture being thereby shrouded in fog, as well as the whole surface of the plates becoming degraded with veil. This can easily be accounted for by the known liability of alkaline pyrogallol at normal strength having probably the greatest reducing power over both exposed and unexposed silver haloids, and at the same time explains its tendency to fog a solarised image.

The *data* for exposure which Mr. Frewing supplies should enable one to arrive at a correct time after a few trials; but, to our thinking, the kernel of his communication lies in the circumstance that he employs ferrous oxalate as a developer. Now, ferrous oxalate, it is hardly necessary for us to point out, of all developers in actual use, is at the bottom of the scale on several heads. In cases of under-exposure, its powers are much circumscribed; its density-giving qualities are not so easily brought out, as those of other developers; in over-exposure, it is correspondingly inert, while it attacks the unexposed film with infinitely less energy than other developing reagents. In fact, its very drawbacks in ordinary negative work are those which in the case under notice are likely to be most efficacious.

Herein probably lies the secret of Mr. Frewing's success, to the particulars of which we draw attention in the hope that others will repeat his experiments. For, as we have before remarked, it is obvious that the plan is available for other purposes besides the production of reversed negatives.

CARBON PRINTING.

As a feather cast upon the waters shows the direction of the tide, so the annual Exhibition of the Photographic Society of Great Britain may be taken as an indication of the advancement or otherwise of different photographic processes. Allusion

was made last week to the fact that the carbon process is better represented in Pall Mall this year than it has hitherto been. Therefore it may well be assumed, with other knowledge we are in possession of, that the process is now being more extensively worked than at any previous period, not only for large sizes by the profession, but also amongst amateurs for small work. It is not at all surprising that this should be the case when it is considered that, apart from the undoubted permanence of the prints, a greater variety of effects—now so much in demand—are to be obtained by it than by any other process, or, indeed, by all the other processes combined.

There is not a process that will yield effects that cannot be got equally as well by the carbon method, while by it many others can be secured that would otherwise be impossible. When all these advantages are enumerated, some of our younger readers may—and not unnaturally—inquire why a process combining so many qualifications was not more generally taken up by photographers in the past. For their information on this point a few words may not be out of place, as it will explain the different conditions of working then and now.

When the carbon process was first introduced, now some thirty years ago, it was the subject of a patent, and heavy charges were made for licences, while, at the same time, the process was troublesome to work. For example, the exposed tissue had to be cemented to paper with indiarubber for development, and afterwards transferred to its permanent support by treatment with benzol. At that time the only real advantage that could be claimed for the process over those in general use was permanence, while the quality of the results, for small work at least, was inferior to what could be obtained in silver. Simplifications followed, indiarubber was dispensed with, the single transfer method was introduced, and was generally adopted for large sizes.

Some sixteen or seventeen years ago considerable impetus was given to the process by an ingenious Frenchman, M. Lambert, who demonstrated that by his modified method of working small prints could be produced which were quite as good as, if not really better than, those on albumen paper. This modification was vigorously exploited by him, and at the time some were sanguine enough to predict that the knell of silver printing was sounded. Progress was, however, considerably impeded again by patent rights, and the way in which they were dispensed. Exclusive licences were granted for certain towns and districts, the purchasers of which could not, or would not, take the trouble to learn how to master a, to them, new process, while others were precluded from working it by these exclusive rights. In some instances licences were taken without any intention of adopting the system, but simply to prevent more enterprising rivals from taking it up. With regard to amateurs, at this time licences were also requisite, but they were eventually granted at a merely nominal fee.

All patents in connexion with carbon printing have long since expired, so that now the process is open to all. It is only within the past two or three years that the simplicity of the carbon process has been fully realised. Indeed, by some, it is even now considered to be a troublesome one. This is clearly proved by the remarks often heard during the several demonstrations that have been given before some of the newer societies, which are chiefly composed of amateurs and young beginners. Most persons seem surprised, when they see the method worked for the first time, at its exceeding simplicity.

At the present time, amateurs and workers on a small scale are relieved of one of what used to be the most troublesome and uncertain of the operations, namely, the sensitising and drying of the tissue. Some little time ago the Autotype Company—and the example set by them has been followed by other firms—commenced to supply the tissue in small quantities, ready-sensitised, cut to the standard sizes, and in the proper condition for use. This has conduced more than anything else to popularise carbon printing amongst small workers. Sensitising tissue is a somewhat messy operation, and those familiar with the subject know quite well that the drying of it, so as to obtain it uniformly in its best working condition, is a somewhat ticklish operation without suitable arrangements. It used to be said, and not without reason, that more skill was required in sensitising and drying of the tissue than in any other portion of the work. It will now be seen why the practice of carbon printing has of late become so much more popular, and promises to become still more so amongst amateurs and others aiming at variety of effects.

By the carbon process pictures can be obtained in every conceivable colour, with any surface—from the highest enamel surface to that of the roughest of drawing papers—and, indeed, on almost any material. If the single-transfer system be adopted, it becomes one of the most, if not *the* most, simple printing process to work. The exposed tissue is merely squeegeed on to the paper, then treated with warm water until the image is sufficiently developed. A short immersion in a solution of alum and a final rinse in water complete the work, while an absolutely permanent picture is secured. Where is a simpler process than this? True, for single transfer, a reversed, as regards left and right, negative is necessary, but negatives on celluloid fulfil this condition, if they be printed through the celluloid. With the thicker films there will be, practically, no loss of sharpness if the exposure be made to a tolerably direct light, and with the thinner ones any light will suffice to secure sharp impressions. Objections to carbon printing have been raised by some who have in times past decried the process, because the image cannot be seen while printing; therefore the correct exposure cannot be judged. In doing so, however, they quite overlooked the fact that the same remark would apply equally well to the taking of negatives, the use of bromide papers, and other photographic operations.

In the carbon process the latitude in exposure is so great that an error of fifty to a hundred per cent. either way does not really mean the loss of the print, it is merely a question of time and temperature in the development. Furthermore, in this process the print, when wrongly exposed and made right in the development, is of the same colour and tone as that of those which have been correctly timed, a condition that does not obtain in any of the silver processes.

A NOTE ON STANNOTYPE FOR TRANSPARENCIES.

In our editorial article a fortnight ago on *Stannotype*, although mention is made of the necessity for the double safe edge and also of the high lights of the transparency being as clear glass as the safe edge, it has been suggested to us that scarcely sufficient empasis was laid on this, for lantern slides especially, all-important point.

We are too prone to consider that a negative or a transparency, if in correct gradation, may be *copied* perfectly, although a veil or slight fog may exist in the original, and such may, indeed, be the case in ordinary copying, but not so

with Stannotype. The high lights *must* be absolutely clear glass, for this very cogent reason.

The clear glass "safe edge" of the transparency, from which the gelatine relief is made, represents the greatest possible action of the light, and, consequently, it forms the thickest or highest portion of the relief; and, extending as it does round all four sides, it regulates, not only the depth of the relief, but also its evenness of thickness. Upon the wall or ridge formed by the safe edge the platen of the printing press rests when screwed down, and the print is formed by the gelatinous ink solidifying in the hollows lying below its level.

It requires but a moment's thought to convince one that, if the high lights of the transparency are veiled, the light, in printing the relief, does not act so powerfully as through the clear glass "safe edge," and, consequently, the highest lights in the printing would stand at a lower level than it is possible to screw the press down to. It follows as a matter of course that no variation in the density of the ink and no alteration in the pressure will avail to prevent a layer of coloured gelatine between the high lights and the paper or glass support of the picture and the consequent tinting or degradation of the whole image.

It is easy to realise the extreme importance of this matter when it is put in this way, and the late Mr. Woodbury used to demonstrate how slight a veil in the transparency served to ruin the relief. When we remember that for decorative, and even for ordinary, copying purposes some people claim that a slight veil in a transparency is an advantage, we think it is important for this purpose to point out the difference.

For amateurs' use, the method of making tissue preferred by Mr. Woodbury will be found more convenient than the one given in our previous article. It differs only in that the pigmented gelatine, without bichromate, is poured on to paper, previously damped squeegeed on to levelled glass, instead of on to collodionised glass. This enables the "tissue," when "set," to be stripped from the glass support, so as to have the great advantage of drying from *both* sides. In order to prevent its "cockling" in drying, Mr. Woodbury used to fix the edges between light frames, hinged in pairs like a double slide, which, while keeping it straight, allowed free access of air. A slight advantage is also probably gained if there should be any dust or other particles in the gelatine, as these will settle down in contact with the paper, which is the portion of the gelatine film that is washed away in development. On the other hand, there is the risk of dust particles attaching to the other or picture-forming surface. The bichromate may or may not be added to the coloured gelatine, but, from our own experience, we think the method of separate sensitising will be found most convenient for amateurs.

A New Curve Measurer for Lenses.—The accurate measurement of the curvature of a lens is a matter of great importance to the practical optician, and an intrument termed a spherometer is used for the purpose. Certain disadvantages attend the use of existent instruments, but recently the Zeiss Company have made a new apparatus, after a design by Professor Abbé, which is of such delicacy as to be able to measure to the twenty-five-thousandth of an inch. The accuracy and delicacy of the instrument is such as should render it of very great value.

A New Method of Packing Plates.—Mr. A. Cowan has lately shown a method of plate-packing, which we believe has been successfully in use for some time by Messrs. Marion. The device employed is simply that of cutting through the backs of the plates without separating the films. This allows of two plates—say, two quarter-plates from a $6\frac{1}{2} \times 4\frac{1}{4}$—being folded face to face and packed in that state. Mr. Cowan has practically demonstrated that, given accuracy of cut, there is no abrasion of the films to be apprehended, while they may be easily separated as wanted without the slightest fear of tearing. Obviously, for smaller sizes, no better system of packing could be devised.

Photography in Lunatic Asylums.—It is stated that occasionally difficulties arise about the identity of persons committed to public asylums should death take place while they are retained as patients. In consequence of this, the Asylums Committee of the London County Council have now given directions that each patient shall be photographed on arrival at the asylum. This has necessitated the provision of the necessary apparatus, and at Colney Hatch a studio is being built, and one of the officials has been appointed photographer. The cured patients on leaving will, it is further mentioned, also be photographed, and it is possible that a comparison of the two photographs will be of interest to scientists. We trust, however, that such photographs will be strictly confined to scientific scrutiny. It would add a new terror to the existence of the poor if it were known that their counterfeit presentments, taken while they were in a condition of temporary insanity, were afterwards to fall into any but responsible hands.

A Practical Method of Timing an Instantaneous Shutter.—Under this heading a letter was recently published in the columns of the *English Mechanic* which contains much useful matter to those interested in this subject. Discussing unfavourably to its merits another project, the writer, Mr. J. B. Bent, of Oldham, suggests the use of a long pendulum, say a bob of lead at the end of a light wire twelve feet long (using wire to prevent any rotation of the bob):—"Attach a silvered bulb to the centre of the weight. It can then be shown that, if the bob of the pendulum be pulled sideways until it is two feet five and a half inches from the line of wire when at rest, the velocity of the bob at the lowest point will be four feet per second. This will vary very slowly about the lowest point of the swing, so that it will not matter if the shutter is not opened at *exactly* the lowest point." It is obvious that a little careful measurement of the plate exposed under these conditions would give with a very fair amount of accuracy the time of exposure.

Stills and the Excise.—Many photographers are in possession of small stills with usually Liebig's condensers, for the production of distilled water of ascertained purity, and a good proportion of this number are unaware of the probable existence of any Excise regulations that render such stills illegal. The Council of the Institute of Chemistry have taken this matter under their consideration, and have written to the Inland Revenue authorities in regard to the matter. They have received a reply which we think may advantageously be brought before our readers:—"Having laid before the Board of Inland Revenue your letter of the 27th July, I am directed in reply to acquaint you, for the information of the Council of the Institute of Chemistry, that the Board have no desire to extend the obligation to take out a licence to analytical chemists using stills solely for the purpose of distilling water. If an analytical chemist called upon to take out a licence by one of the Board's officers will submit his cause to the Board, they will be prepared to give the matter careful consideration." It will be seen by this that the necessity to take out such a licence by any one holding a still of a certain size is by no means looked upon as a dead letter. It would be, therefore, no ill-advised step if the Council of the Photographic Society of Great Britain would follow in the footsteps of the Institute of Chemistry.

Solubility of Silver Salts in Alkaline Haloids.—Herr C. Schierholz, in an article in a foreign technical journal, regarding the separation of the halogens, describes how, incidentally, he has investigated the solubility of the halogen salts of silver in the

halogen salts of the alkaline metals. Photographers have long been aware of the solubility of silver iodide in solutions of either silver nitrate or iodide of potassium. It has also been common knowledge that sodium chloride solutions would take up an uncertain amount of silver chloride, but the governing conditions were little understood. Herr Schierholz has thrown some light on the matter. He finds that the solutions referred to dissolve four or five times as much of the silver salts at their boiling point as they do at the ordinary temperature of the atmosphere. Further—a fact familiar to old wet-plate workers—in one direction at least, the concentration of the solutions has a marked effect on this "insoluble" silver salt; for example, a ten per cent. solution of sodium chloride and a one per cent. of potassium iodide dissolving scarcely any of the corresponding silver compounds. The very great difference between chlorine and iodine is shown both in the relative solubility of silver chloride and silver iodide, and in the different solvent powers of the halogen alkali salts on silver nitrate, chloride, &c., the powers of bromide lying between the two. He gives us instances:—A twenty per cent. solution of sodium or potassium chloride which dissolves hardly a trace of silver iodide, whilst potassium iodide in concentrated solution dissolves ninety per cent. of its own weight of silver iodide, which is increased four or five times when the potassic solution is raised to boiling point. One peculiarly interesting point he elucidates is that mixtures of these alkaline halogen salts in particular proportions are unable to dissolve as much of the silver salt as each can before admixture. To a certain extent the above investigation would appear to show that the old theory about the relative value of sodium chloride and hydrochloric acid for throwing down the silver from waste solutions will have to be reconsidered. But, whether or no in practice salt solution does or does not dissolve any of the silver precipitate, it is certain that quite apart from any of the improvements recently suggested, the use of the acid facilitates the deposition of the precipitate.

ESTIMATION AND DEHYDRATION OF SILVER OXIDE.

[American Journal of Science.]

In some analytical determinations it became necessary to estimate silver oxide, and the question arose at what temperature the moist oxide could be most perfectly dried, and also at what temperature it began to lose oxygen? As no such data are to be found, they had to be determined, and the results obtained may possibly be of use to others.

Moist oxide precipitated by perfectly pure sodium hydrate obtained from metallic sodium, and thoroughly washed, was dried at 100° C. for twenty hours. Of this material 1·5528 gramme were taken and heated again to 100° for twenty more hours, after which heating it weighed 1·5524, a loss of 0·0004 gramme. It was next heated to 160°–165° C. for five hours, and was then found to weigh 1·538 gramme, a loss of 0·0135 gramme. It was then replaced in the oven, and heated five more hours. No loss whatever of weight could be detected resulting from this third heating. The oxide was then ignited, and gave 1·4358 gramme of silver.

Taking the atomic weight of silver at 107·66 and O=16, argentic oxide should contain 6·92 per cent. of oxygen (more exactly 6·917).

From the foregoing it follows that moist silver oxide dried for forty hours at 100° lost by ignition	7·51	per cent.
The same oxide with ten hours' drying at 160°–165° C. lost by ignition	6·70	,,
Calculation for Ag_2O gives for O	6·92	,,

It follows that after forty hours' drying at 100° the oxide had reached a constant weight and still retained 0·59 per cent. of moisture. When heated to 160°–165° till constant in weight, it had lost the 0·22 per cent. of oxygen.

It was next attempted by a shorter second heating and a lower temperature to expel the water alone. Silver oxide was dried for twenty hours at 100° and was then heated for two hours to 130°–135° C. Of this oxide 1·8043 gramme was ignited and left 1·6701 gramme of silver, indicating a loss by ignition of 7·44 per cent. This was only ·07 less than when the heat was not raised above 100° C., showing that the oxide is not dehydrated by exposure to a temperature of 130°–135° C.

The conclusion to be drawn would apparently be that the point at which the last portions of water were driven off was very close to that at which oxygen began to be disengaged. It can be shown, however, that this is not so, and that oxygen is lost long before the last portions of water escape. This can be proved by the delicate photo-chloride reaction, which I described some years ago. If the silver oxide dried as above described at 100° C., till it reaches a constant weight, is moistened with dilute hydrochloric acid, a chloride is obtained, of a deep lilac colour. This colour always denotes the presence of hemichloride, due to the fact that a certain portion of the oxide had been reduced to hemioxide. The hemichloride combining with the white chloride forms a photo-chloride characterised by the colouration just mentioned.

A really accurate estimation of silver oxide is therefore impossible, as it loses oxygen too easily.

Silver oxide is not supposed to form a hydrate; nevertheless, some portion of moisture remains united with it more strongly than some part of the oxygen, with which it combines to form a strong base.

But it also appears that the loss of oxygen is very small and soon ceases, even at 160°–165° C., for, after five hours' exposure to that temperature, the weight became constant.

M. Carey Lea.

AMERICAN NOTES AND NEWS.

Retouchers' Associations.—Several of these are being formed in the United States, and that at St. Louis, Mo., is said to have a good membership. The object of the Association, according to Mr. R. W. Drew, Secretary of the Order, is "to elevate the photographic business, to secure help for those who need it, and to find positions for the members who are out of employment." An excellent programme.

A Bureau for Testing Lenses.—The *American Journal of Photography* enters a plea for the establishment in America of a *bureau* "to which one can send a lens to be examined as regards its definition, distortion, focal length," &c., and hints that such a *bureau* may shortly be opened in the near future if there is a sufficient demand for it. No doubt such an establishment would be modelled upon the lines of that recently instituted at Kew.

"Diffusing" Plates.—The half-tone screen-plates used by photo-engravers are being applied to photographic portraiture in America. The screen is placed before the plate which is to be exposed, the result being, upon development, a negative broken up, which, when printed, produces a portrait resembling a half-tone photo-engraving. Specimen prints by this method recently appeared in one of the Canadian photographic journals. The idea is tolerably old, but the effects are pleasing variations in portrait photography.

A Star Camera.—The star camera in use by Professor Russell, Government Astronomer at Sydney, is said to be in some respects unique. It has two combinations of lenses for use in the enlarging camera, one having a magnifying power equivalent to a focal length of 47 and the other of 180 feet. Very satisfactory pictures of the moon, says *Anthony's Bulletin*, as large as five and a half metres in diameter can be made with the former in from three to four seconds, though it has proved more advantageous to reduce the aperture and increase the time to about twenty seconds. The enlarging lens is constructed of two lenses of equal focus, mounted convex sides together, and separated five-eighths of the sum of the foci of the two.

Magnesium as a Source of Light.—Mr. Frederick J. Rogers, in the *American Journal of Science*, after pointing out that the spectrum of burning magnesium approaches more nearly to that of sunlight than does the spectrum of any other artificial illuminant, says that the temperature of the flame, about 1340 deg. C, lies between that of the Bunsen burner and the air blast lamp. The "radiant" efficiency (the ratio of luminous energy to total radiant energy) is higher than that for any other artificial illuminant, with the exception of the electric discharge in vacuo; while the total efficiency of the magnesium light is about 10 per cent. as compared with a quarter of one per cent. for illuminating gas. He concludes that it is certain that per unit of energy expended, the light-giving

power of burning magnesium is from fifty to sixty times greater than that of gas.

Drawing Photo-micrographic Objects.—According to *Anthony's Bulletin*, Dr. H. G. Piffard has done much to simplify the drawing of photo-micrographic objects, by means of his application of the prism to the microscope. His method is to insert a right angle prism by means of a short tube in the place of the eye piece of the microscope, and on one of the square faces of the prism another short tube to hold the ocular. The object then having been placed upon the stage and focussed, a piece of plain drawing-paper is placed under the ocular and the room darkened, when a brilliant image will be apparent on the drawing-paper. It is evident that in this way the artist has the advantage of perfect freedom both of his eyes and hands in his work, and can trace the minutest detail with ease and accuracy.

Wants to be a Photographer.—The following letter was lately received by our *confrères* of the *American Journal of Photography*:—"Mister Editer, Sir, Please unt let me a know wat a compplead fotegraf outfids will cost me, mabe camera, chemicals, unt all complead to make picters wid from 3¼ × 3¼, 4 × 5, 4¼ × 6½, 6½ × 8½ i would likes to stard in de bisness as I never had no expereance, vould likes you to gives me some informations i got I of your Journals unt looks dru de pak for were to puy one camera's und ader dinks. Now pleas unt dells me vich of dem cameras can I takes pictures in a room wichout skye lite, tells me can I take a biuldings picture clear on cloudy weathers, pleas unt kin I takes gems & tintypes wichone cameras I vold likes to take tintypes unt outher pictures pleace unt fine the price all complte how much money I want to start in do dink you can tel me all aboud id so I can makes a compplead pictures ov my own expereances i am a mittle age man unt got a gute schul edencations give me full information unt I vill starts rite in."

A SERIOUS BLOW-UP: A REMINISCENCE.

The recent disastrous collodion explosion in Paris so vividly recalls a terrible experience of my own that I cannot help writing about it. The event referred to in your pages of September 16 took place more than twenty years ago, and yet it is as vividly before my eyes at this moment as though it had occurred only yesterday.

As collodion is still largely used by enamellers and others, and there is a collodio-bromide dry plate process looming in the dim future, a narrative of the drama by the chief actor left to tell the tale may serve a good purpose in showing modern workers that this useful compound, though a good servant, is a terrible master.

Many of the old readers of this Journal will remember that, twenty years ago, I manufactured collodion in considerable quantities for sale, and that it was largely used by the photographers of that period. The operations involved in the manufacture of collodion in large quantities are anything but agreeable. First, there is the manufacture of the pyroxyline, which for modern readers may be called a mild form of guncotton—though its mildness will soon disappear if it be ignited when confined in any earthenware jar, and I hope, therefore, my readers will take my word for it, and not make the experiment—and is made by acting upon cotton with a combination of nitric and sulphuric acids. When separate, the latter acid gives off no fumes, and those from the nitric acid are only noxious when very near to them; but when these acids are combined, heavy fumes of the most deadly character are given off, and with every possible precaution to convey them into a flue, some will get down the throat and into the lungs, and to this day I have an irritating affection of the mucous lining of the nostrils and throat which is chronic, and is no doubt due to the action of these combined acids all these years ago. It will be seen, therefore, that the manufacture of this necessary ingredient in the compound called collodion is not at all a desirable occupation. So much, therefore, for the pyroxyline; now for the mixture.

Certain proportions of alcohol and sulphuric ether are combined, and into this is introduced the pyroxyline, which, if properly made, will be perfectly soluble in it. In small quantities this is a very simple operation, and gives no trouble; but where many gallons are made at a time matters are considerable changed. The decanting of the alcohol into the mixing vessel is bad enough, for it produces the same effect on the wits as a very small quantity, disguised by flavour and called brandy, would do if taken internally, diluted with hot water and further made palatable by the aid of a lump of sugar. The decanting of the ether is, however, a far more serious matter. This spirit is always sent out by the manufacturer in bottles called Winchester quarts, and it would gladden the heart of the toper of to-day if this old-fashioned measure were used in the taverns haunted by him, for each quart is half a gallon. The emptying of these bottles is necessarily a slow operation, and by the time the contents of a sufficient number of them have reached the alcohol, the fumes, in spite of every precaution, have produced all the effect of a heavy bout of drinking on the brain of the operator, and he would find it absolutely impossible to keep his toes on a straight chalk mark. Fortunately for him, however, the effect soon goes off, and after staggering about in the open air for a short time, he is soon himself again.

It will be seen, from the above, that collodion making is by no means a pleasant occupation, and it can easily be imagined, therefore, that the maker is glad to prepare it in considerable batches and let them settle and fine down until they are ready for bottling off. This will explain why, on a never-to-be-forgotten day in 1869, I had a large quantity of collodion in stock, all ready for decanting. It was the last day of November, and the weather had been unusually cold for the time of year. In fact, it had been freezing for several days and there was skating in the fens. The collodion was stored in some splendidly made glass barrels, each one with a capacity of six gallons. They were considered triumphs of glass casting, and came from the German department of the Great Exhibition of 1862. Each barrel had a large glass stopper at the top, and a glass tap in the end. I found these barrels extremely useful for my purpose, for the sediment settled down in the belly, and the clear liquid was easily drawn off by the tap. They had been in use for years and had become well tried old friends. The cold weather was really the cause of the accident, as will shortly be seen. These barrels had been filled on one of the cold days, and they stood,—four of them all of a row, making twenty-four gallons in all—in a room parted off from my studio, which, fortunately for me, was on the ground, and at the bottom of a fairly long garden, and had no fireplace in it. No light was ever taken into it, for well knowing the dangerous character of the materials, all the operations were conducted by daylight.

On the memorable day in question I had been very busy with sitters in the studio, and, in consequence of the great cold, a good fire had been kept up all day. The door leading into the room in which the collodion was stored had been left open, and the heated air had travelled into the storehouse. In filling the barrels I had overlooked the intense cold, and had not allowed a sufficient margin for expansion. The day was waning, the last sitter had gone, and the fire was nearly out, but the studio was still comfortably warm. I had been called up to the house on business, and had been there only a short time when the boy who assisted in printing came rushing in with staring eyes, and exclaimed that one of the barrels had gone crack! I rushed down the garden, and into the studio. There was an overpowering smell of collodion, but there were only a few dull red embers in the grate, and I knew that flame was needed to ignite collodion, so I felt the fear of an explosion was at an end, and peeped through the open door to gauge the amount of mischief done. Part of the end of one of the barrels was out, and a pool of collodion was slowly trailing its way along the floor. The stopper had evidently got fixed, and the heated air had so expanded the collodion in all the other barrels that they were each full up to the stopper. In the ill-fated one something had to yield; the stopper would not, and so the end gave way. It only took a second to see all this, and I rushed to one of the windows, which fortunately opened outwards, and was in the act of pushing it as far open as possible so as to let out the fumes when ——? I cannot find a word to describe the sound. It was not like the sharp crack of near artillery, nor the roar of thunder; it was a hoarse boom, and instantly I was carried out with a force mightier than a gigantic wave of the sea, and deposited on a grass plot some twenty feet from the building. Immediately followed a series of thunder charges of artillery (probably from the explosion of the other barrels), and the sharp rattle of musketry, which was the roof of the studio sent flying skyward, and then descended a hailstorm of finely splintered glass. It was a great mercy for me that they were very fine splinters, for several entered the exposed parts of my body, and I carry to this day several scars as *souvenirs* of that fateful day. I was not quite stunned by my fall, for I was carried—fortunately for me—outward, not upward.

In a second or two I was on my feet, and mechanically put my hands over various parts of my anatomy to see the extent of the damage. I picked out a few pieces of glass sticking variously in my head and hands. The blood I did not heed. With a thankful heart I found I was comparatively whole, and all the rest seemed as nothing against this great fact. The first impression that reached my brain

on regaining my feet was a group near the house, afraid to approach nearer, and distinct among them the maid-servant, with brightly illumined face, distorted by terror. She was frantically wringing her hands, but otherwise seemed paralysed by fear. To see all this was the work of an instant. I was thrown out face foremost, and therefore for a few seconds did not see the extent of the mischief. I had now time to turn round and face the scene—and what a scene! The whole place was a raging furnace. There was no smoke; intensely white flames soared forty feet into the air, and through the openings in the wall, formerly occupied by windows, I could see chairs, tables, cameras, stands, in fact, everything burnable, roaring away, each adding its contribution to the mighty blaze. In a very short space of time there were seven engines on the scene; but, practically, there was nothing to be done. They played upon the charred remains, but everything of value had been totally destroyed long before the firemen could commence action. Of course, the garden was speedily filled by London roughs of the too-well-known type, who seemed to spring out of the bowels of the earth, ready armed for mischief. They proceeded to smash and wreck a glass shed used for printing, and which was in no danger from the fire. Fortunately for me, two or three policemen appeared on the scene, and cut short their ruffianly efforts at wholesale destruction.

A stream of gas from the place where the meter once stood still blazed away, and explained the cause of the catastrophe. I had formerly tried heating the studio by a gas stove, but found it too expensive; I, however, carried a pipe into the dark room, and connected it with a very small home-made gas stove, to keep the nitrate of silver bath warm in winter. I had altogether forgotten this gas arrangement. Out of sight out of mind. I was right in my surmise that the dull-red embers of the expiring fire were harmless, but the inrush of air from the open window drove the etherial fumes from the collodion in the direction of the dark room, and the moment they touched the gas flame away they went to mingle with the ether of the sky, they were free for further action for the weal or woe of mankind. The collodion was no more; but I was left a sadder and a wiser man. Next day I found I had something left from the wreck. There were a number of brass tubes with a semi-transparent treacly substance running out at the ends. A close inspection revealed the name of "Dallmeyer" on most of them. In happier days they had been lenses.

VALENTINE BLANCHARD.

EXPERIMENTS IN COMBINED TONING AND FIXING.

[PHOTOGRAPHIC TIMES.]

OF the one hundred and twenty articles contributed to "The American Annual of Photography for 1892," no one has probably led to so many inquiries for special information and to so extensive discussion as that on the combined toning and fixing bath described on page 87. Of the many statements made as to its efficacy, about thirty per cent. have spoken in terms of high satisfaction, while the rest confessed an inability to procure with it anything like the desired results. But the fact that a few of the many who have worked the bath have had the same results I have enjoyed is something in its favour. To discuss its chemical composition, therefore, would be needless, were it not that the bath has proved not to work equally well under different circumstances.

While conducting the practising class of the Chautauqua School of Photography during the present extremely hot summer, it was found the bath as originally prepared worked with much greater energy, and, whereas during last winter it took from fifteen to twenty minutes to tone and fix thoroughly chloride of silver gelatine paper prints, toning was completed within four or five minutes, evidently too short a time to secure a perfectly fixed proof. To prolong toning, the chloride of silver of the original formula was left out; toning proceeded much slower in the beginning, without, however, rendering the tone as agreeable as with silver, and without the whites being as brilliant and pure as formerly. E. Valenta's formula for a reliable combined toning bath (see the *Photographic Times*, Vol. XXII. page 343) appeared quite *apropos*, and it was concluded to give it a trial. The author's opinion, that when, alongside of the formation of sulphide of silver, gold is also substituted for a portion of the metallic silver of the print, the result is permanent for all practical purposes, appeared reasonable and convincing enough to give the bath a trial. The formula is as follows:—

Water	500 cm.
Hyposulphite of sodium	200 gm.
Sulphocyanide of ammonium	25 gm.
Nitrate of lead	10 gm.
Alum	20 gm.

The bath is diluted with an equal volume of water, and to each 200 cm. added from 7 to 8 cm. of a 1 per cent. solution of chloride of gold. With all that has been said in favour of the bath, it has not worked satisfactorily in my hands. In the first place, there is far too much lead in it. Bradfisch & Pierce's improved chloride of silver gelatine paper of decided acid reaction tones in it to a bluish-grey colour within less than four minutes. After subjecting from fifteen to twenty 5×8 prints to 24 ounces of the bath, it became frothy and thickish, toning proceeded still more rapidly, the gelatine film appeared to be in a state of dissolution, and after the washed print had been squeegeed upon glass, ebonite or tintype plate, it adhered tenaciously and refused to strip off under any circumstances. Reducing the quantity of lead to one-fourth, one-sixth, and one-eighth prolonged the process of toning, but all other effects remained the same. Explanation of a part of the difficulties encountered was found in a recent number of *Photographisches Archiv*, where it is stated that nitrate of lead, and still more so sulpho-cyanide of ammonium, is a powerful solvent of gelatine when at a temperature of 20 deg. C. (68 deg. F.).

Experiments have proved Herr Liesegang's assertions to be perfectly correct, with the exception, perhaps, that with the presence of lead nitrate and sulpho-cyanide of ammonium gelatine dissolves at a still lower temperature than stated.

With these several experiments the practicability and reliability of the Valenta bath had become more than doubtful, and a reconstruction or modification of our old bath was resolved upon. Keeping in view what Valenta had said of toning with lead and simultaneously with gold, and that slow toning only can secure perfect fixing, I compounded a bath that has so far answered all possible demands. The tones produced are agreeably warm, the whites pure, not tinged yellow, fixing appeared to have been perfect, and a reasonable permanency of the print is hoped for.

Dissolve one pound of hypo in 32 ounces of water and 3 ounces of alum in 32 ounces of water. Allow to settle, heat to 120 deg., filter and add 22 grains of nitrate of lead. To 20 ounces of this solution add 5 grains of terchloride of gold dissolved in 2 ounces of water. With 20 ounces of this solution fifty 5×8 Bradfisch & Pierce's emulsion paper, or an equivalent of larger or smaller dimensions, can be toned and fixed to perfection. After toning this number of prints the gold is exhausted, and the bath should not be used any longer. A well-printed-out picture tones in from twelve to fifteen minutes, sufficiently long to secure a thoroughly fixed print. When the tone of the picture begins to look purplish by transmitted light, no matter how the colour may be in reflected, remove it at once to *running* water and continue to wash for about one hour, when the print may be dried or squeegeed. There is alum enough in the solution to harden the film without resorting to an extra tanner, and carbonate of sodium before or after toning and fixing is not at all necessary. The finished prints have a beautiful deep purple colour and the whites are perfectly pure.

The many inquiries made about toning and fixing gelatine prints in a combined bath, the repeated reports on total failures, and the very miserable prints sent for inspection from many sources have induced me to write down these my latest experiences, for the readers of the *Photographic Times*. There is only one question to be decided, Are gelatine prints toned in a combined bath reasonably permanent? An argument in favour of an affirmative answer to the question is an exhibit of albumen prints displayed at the Chautauqua School-rooms. They were toned and fixed in a combined bath similar to the one above described as early as in the summer of 1852, and after a lapse of forty years have preserved a generally good tone, with the whites but slightly tinged.

CHARLES EHRMANN.

STEREOSCOPIC PHOTOGRAPHY.

[Birmingham Photographic Society.]

IT is with a feeling of diffidence that I address myself to this subject this evening. In the first place, the last time it was discussed before the Society I found myself totally opposed to it, and it is a somewhat anomalous position to place one's self in to be found advocating at a meeting of this sort the very thing one had opposed previously. In the next place, there are gentlemen in the room who know far more about the subject than I do, and who are better qualified to speak upon it than I am. The difficulty the Council had, however, when I was selected to read the paper was this, that no matter how diffident I might be, they were still more so, and that must be my apology for any shortcomings which may appear in my treatment of the subject.

STEREOSCOPIC PHOTOGRAPHY NOT DEAD.

Some of our members have obtained a great deal of amusement out of this subject by chaffing those who advocate its popularity. One gentle-

man, for instance, avers that it is as dead as Queen Anne. He, however, is careful not to say to which Queen Anne he alludes, because it is very evident that stereoscopic photography is not dead. On the contrary, its claims are being urged more every season, and I venture to predict that it will yet become the most popular form of amateur photography. Another joke made at its expense is that in instantaneous pictures made by its aid moving figures are so tantalising, that a man in the act of walking presents such a realistic appearance, that one feels a desire to drop a penny in the slot to make him move, or even to take more drastic measures still. Well, gentlemen, I claim that that is an additional charm to the stereoscopic worker, viz., to depict Nature as it really is, or, shall I say, as we really see it. I hope to prove to you before I finish my paper that it is impossible to see an ordinary photograph adequately represent any subject. A friend who is present remarked a short time ago in the club room that we got our results by means of a trick, and that it was not a genuine representation. Well, it is for me to prove that it is not a trick, but the most correct and the only truthful way of delineating a view or picture upon a plane surface. If you wish to produce in a natural manner several planes, there is, so far as I know, no other way of obtaining the result than by stereoscopic photography. If I hold a book in my hand at arm's length edgwise, and close one eye, I see the edge of the book only; but if I open the other eye, still holding the book in the same position, I see not only the edge, but also a portion of the side of the book, which proves that with two eyes two distinct pictures are formed which, however, coalesce either by a mental act, which is the most likely theory, or from some connexion between the nerves of the retinæ which at present has not been discovered. Many theories exist, but as they all differ, it is no part of my duty to trouble you by discussing them.

Binocular Vision.

It seems to be upon the whole considered most probable that the power of forming a single idea of an object from a double impression conveyed by it to the eyes is the result of a mental act. If you hold up one of your index fingers close to the eye, and one farther off, you will see that by looking at the one farthest away with both eyes, you really see three fingers. In the same way, by looking at the nearest one, you still can see three fingers, *i.e.*, by bringing the optic axes to bear upon the near finger, the one farthest away is brought to a different part of the retina in each eye, and two fingers are seen behind the one which is really in focus. These experiments might be repeated in numerous ways; but I think I have established the fact, that binocular vision produces two different impressions, which by a mental operation give rise to only one sensation. Now, if we look with both eyes at an ordinary photograph, *i.e.*, taken with one lens, it is evident something must be wanting to adequately represent the subject to us, and all will agree that there is in every photograph, so taken, an appearance of flatness which can only be overcome by aerial perspective, and so when the distance is almost obliterated by atmosphere, and just a dim sensation of the mountains, or trees, or whatever may be at the background of the picture presents itself, it is seized upon as a triumph of photographic art; often by the very men who have done all they can by the use of isochromatic plates, and yellow screens to overcome what they know perfectly well is not a representation of Nature in its best aspect; but which is the best result they can accomplish. The fact, also, that to look at the photograph with one eye only, and then preferably either through a tube or shaded by the hand, will give a partially stereoscopic effect, all goes to prove that for either the most correct representation, or to afford the greatest pleasure to our friends or ourselves, the use of the stereoscope is not only not a trick, but the only legitimate way of showing or looking at our pictures when done.

Why the Stereoscope went out of Fashion.

You may ask if, then, all you say is true, how is it the instrument is gone so much out of fashion; or, as I put it in commencing, "been asleep?" That is easily answered. There is no doubt that great care is necessary in mounting the pictures, which, to an amateur, is only increasing his pleasure in the work, and an incentive to excel; but which to the tradesman, who gets the work done in the cheapest manner possible, and which he accomplishes by employing, probably, young persons, who think but little, and care still less, as to how the slides will look when placed in position, it is not fair to the art to judge of it by its past history. For years I could never look with any pleasure through a stereoscope, because, in order to make the pictures overlap or combine, I had to strain my eyes almost out of my head, and the consequence was that, after looking at about half a dozen views, I had such a headache that I was compelled to give up looking at any more. A few months ago an American called upon me with a new form of stereoscope, and I found that it was a wonderful improvement on any I had seen before, but still there was a slight strain, and I found at last that it occurred more with some pictures than others, and, in fact, with some there was no strain at all, and upon measuring the distances they were mounted apart, I soon found out the reason. More strain was occasioned by those mounted three inches apart, and some were even over this, which made it worse. I found that those at two and three-quarters of an inch were quite normal and easy to look at. I believe that two and a half inches is better for many people, but as I can see two and three-quarter inch views quite easily, I prefer that width, as, of course, I can get, by means of the quarter inch, a larger picture and more subject.

The Optics of the Stereoscope.

Perhaps at this stage it would be well for me to illustrate by a diagram what the action of the lenses in the stereoscope is. I should say that the form of instrument as now used was invented by Professor Brewster. A double convex lens is divided across the middle, and the two helves are set with their thin edges in juxtaposition. In the *Stereoscopic Manual* by Chadwick, which is very interesting and useful to all workers in this branch, he points out that it is possible to construct a stereoscope without lenses at all. He says, in considering the size of the pictures and the dimensions of the box, "When we look at a tree in Nature a mile away, we view it with so little convergence of the optic axes as to be termed practically parallel vision; and as it is by greater or less convergence that we judge distance, we must view the photograph of the tree with practically parallel vision, for it must be remembered that, if we observed the tree with a greater convergence of the optic axes, we should not estimate it at its true distance, but at a nearer distance; and as our eyes are only two and a half inches apart, it is clear that the image of the tree in the two photographs must not be more than two and a half inches apart. This dimension, then, settles the size of the photographs at not more than two and a half inches in width. With normal vision, we cannot conveniently observe anything distinctly at a nearer distance from the eye than eight inches, and the box must be at least eight inches long in order to accomplish this." It was pointed out the last time the subject was discussed in this room, I think, by Mr. Griffiths, that even this simple form of stereoscope was unnecessary, and that with practice it was possible to get the effect by holding the pictures in the hand and by diverging the eyes until parallel vision was obtained. This I tried at for a long time, and at last succeeded in getting the effect; but I thought there was too much strain upon the eyes, and no doubt there was, and for this reason. If we wish to obtain the best result from a photograph, as to the natural size and perspective, whether large or small, we should view it at a distance from the eye equal to the focus of the lens we have used in taking the view, and it is for that reason that most people prefer whole-plate size, as the lens usually employed is about ten inches focus, which may be considered the normal focus of the eye. Now, as it is necessary to use a lens of about five inches focus for stereoscopic work in order to get in the usual angle of view, and by that I mean about the same amount of subject as that obtained with an ordinary quarter, half, or whole-plate lens, it becomes necessary to get the assistance of a lens in order to procure the correct proportion, because it is evident that, if the picture is produced by a five-inch focus lens, and we observe the print at ten inches from the eye, it would appear only one-half its true diameter.

So far as I can see, the object in placing the lenses in this position is to give parallel vision, as well as to magnify the print to its proper size. You will see by the diagram which I have prepared that the ray of light is caused to slightly diverge, and thus place the optic axes in the same position as when looking at the view itself. For this reason the lenses should be mounted not more than two and a half inches apart from centre to centre, as the normal distance between our eyes is approximately two and a half inches, and, consequently, if the lenses are farther apart, as is the case with many stereoscopes, only the thin edges of the glasses are used, and the diverging lines are proportionately more acute, and consequently the true distance is not appreciated, and objects in the picture convey the impression of something much smaller than is really the case. While this objection may also be urged, I think that the more the lenses converge, or, as they are used in the stereoscope, diverge, the greater the strain will be upon the eyes. We may now leave the theoretical for the more practical part of the subject, and I would first call your attention to the convenience of this work over ordinary photography.

Sizes in Stereoscopic Work.

Most of you will, I think, agree with me that quarter-plate work is too small for any purpose except lantern-slide making, snap shots in the hand camera, or carte de visite portraits. Half-plate work is very little better. The views are too small to frame for pictures, and too large to mount in a scrap album, and in consequence the majority of the prints

are left to tumble about until they are spoilt. With whole plate work it is different. You may with this size view decorate your walls with pictures worth looking at, but at what a cost! Plates, paper, chemicals, mounts, and frames, besides the hard labour entailed; and then, after carrying the apparatus five or six miles, finding nothing worth exposing upon! That is one of the pleasures of whole-plate work. Now take the stereoscopic camera. You can use a small and lightly-made camera, a light stand. You can use only one lens if desired, and take a quarter-plate picture for a lantern slide, or if you wish to get a half-plate picture you have only to adapt one lens and remove the dividing screen, and you have with your five inch lens a wide angle picture, or you can carry a seven and a half inch lens, and place in your camera front for an ordinary view. But why take all that trouble? Suppose you see a nice bit, and you want to get a lantern slide, or quarter-plate size for a pocket album, or a stereoscopic view for the drawing-room table, you have it all at once in the one negative; but I can carry you still further. Suppose you think you would like a half-plate picture framed for the breakfast-room or nursery walls, or a whole plate or 12 × 10 for the drawing-room, all you have to do is to enlarge the subject on bromide paper, and you have it.

Now, I ask you, can any other camera give you all these advantages, and I am sure you will agree that it is impossible to get the same results in any other way. There is nothing for you to relearn or to forget before you can produce satisfactory stereoscopic slides. The negatives require a full exposure to prevent chalkiness and in mounting the slides you have to transpose the pictures from left to right, in order that, when looking at the view, you may place the right-hand side picture as taken before the right eye, which it will easily be seen would not be the case unless transposed, from the fact of the pictures being taken inverted. As I mentioned before, I take some object at the middle distance, and measure 2¾ in. from centre to centre, carefully cut the two pictures top and bottom before dividing them, and with ordinary care in mounting, a perfect result is obtained. I place a straight line across the mount as a guide, both for the centre and also to keep the prints upright. I have not thought it necessary to demonstrate at any length before you, because, as I said before, there are no new dodges to learn in order to assist you to success. I hope I have succeeded in removing any prejudices which may have existed in your minds against the subject under discussion, and also in setting forth a few of the pleasures which we who follow it enjoy, I have only to say in conclusion that I do not think any one who has followed it has ever grown tired and given it up entirely, while I think all will agree that a stereoscopic picture properly taken, mounted, and viewed, is indeed a thing of beauty and a joy for ever.

GEO. A. THOMASON.

FOCUSSING AND THE USE OF DIAPHRAGMS.

[Canadian Photographic Journal.]

IN cross-heading this article I have followed the order adopted by the publishers in their invitation to competitors; but, as correct focussing depends to a large extent on the proper use of diaphragms or stops, I shall reverse the order and deal with them first.

The photographic lenses in general use are of two classes, single and compound, and with both stops are employed, although for very different purposes; in the first they are absolutely necessary, while in the second they are only used as a means of improvement.

A single lens, often spoken of as a landscape lens, whether plano-convex or meniscus, cannot be corrected for spherical aberration, the rays from toward the margin coming to a focus nearer the lens than those from towards the centre. The only remedy for this, unless the image were to be received on a concave plate, is the placing of a stop at some distance in front of the lens, so as to cut off the objectionable marginal rays, and let the picture be formed only of such central pencils as come practically to a focus on one plane.

In the case of a compound lens, spherical aberration has to a large extent been eliminated, so that with a full working aperture, as fixed by the maker, it will, if of a good quality, produce a sharp image, but a sharp image of only such objects as are on one plane; an object at, say, twelve feet being perfectly sharp, while those at ten and fourteen are out of focus. This applies most particularly to portrait lenses, but in a less degree to most compound varieties, is generally spoken of as want of depth of focus, and remedied more or less in proportion to the size of the stop employed. This will be easily understood from a consideration of the fact that the rays from the upper and lower margins of, say, a lens of three inches diameter, cross or come to a focus at, say, a distance of eight inches, at a much wider angle than those from the upper and lower edges of, say, a half-inch stop, something, in fact, like as twenty to three. To secure a sharp image of the rays crossing at a wider angle, the focussing screen must be placed exactly at the crossing point, while on those at the much smaller angle it may be moved for a certain distance to and fro without visibly affecting the sharpness. In other words, objects both in front and behind that which had been specially focussed appear sufficiently sharp, and thus "depth of focus" is obtained.

Although the securing of depth of focus be the main object of the stop in a compound lens, it also tends to flatten the field. Except in the case of the new "Anastigmat," it has been hitherto impossible to altogether eliminate spherical aberration from even the best type of compound lens, and although the depth of focus is not needed there, the small stop is absolutely essential to secure perfect marginal definition.

Of course, it goes without saying that the smaller the stop the less will be the light that is transmitted to the plate, and consequently the longer will be the exposure; but the amateur, and the professional also, as he is not infrequently in blissful ignorance of the nature and properties of his lens, should remember that the size of the stop *per se* has no meaning, and only becomes intelligible when its relation to the focal length of the lens is known.

Stops, therefore, should always be thought of and spoken of in that relation, viz., as *f*-x, x being the proportion the aperture bears to the focus of the lens. Until a few years ago each maker made the apparatus of his stops according to his own fancy, although there was a kind of understanding that each smaller stop required twice the exposure of its next largest neighbour, but modern opticians generally adopt what is known as the U.S., or universal system.

The largest working aperture of the average portrait lens is one-fourth of its focal length, and the stop, consequently, is marked *f*-4. The U.S. takes that as the unit, and also marks it No. 1. A little calculation shows that if the aperture be reduced to 1½-fifths of the focal length, it will admit just half the light admitted by the one-fourth, and it is marked *f*-5·6, with the U. S. No. 2, and so on through as many stops as can possibly be required. Thus:—*f*-8, No. 4; *f*-11·3, No. 8; *f*-16, No. 16; *f*-22·6, No. 32; *f*-32, No. 64; *f*-45·2, No. 128.

In this way not only is the relation which each stop bears to the focal length of the lens shown, but also the exposure required with any one stop on any particular plate being known, the time of any of the others is seen at a glance. For example, if it is known that *f*-22 needs two seconds, *f*-32 will need four, and *f*-16 only one; or if *f*-4 requires one second, then the U.S. numbers behind each stop give the respective number of seconds needed.

Amateurs whose lenses are not so marked could hardly take the trouble to alter the openings of their stops, but they should certainly ascertain the *f* value of each of them, so as to be able to communicate intelligibly with their brethren. The first step is, of course, to ascertain the equivalent focus of the lens. If a single one, all that is required is to focus carefully some distant object, and measure the distance between the back of the lens and the focussing screen. With a compound lens the operation is more complicated. There are various methods by which it can be accurately accomplished, some of which may be printed in the future; but, in the meantime, it may be managed with sufficient accuracy in a simple way. Focus, as in the case of a single lens, on a distant object, and measure the distance between the diaphragm slot and the focussing screen, which generally will be near enough for most practical purposes. Suppose the focus is found to be ten inches; bring that to tenths=100, and ascertain the number of tenths in each of the stops. Suppose one should be four-tenths; divide the 100 by 4, which will give 25, and shows that stop should be marked *f*-25, and so on with all the rest. A smaller fraction than a tenth, a sixteenth, or, better still, a millimeter, for the reduction of the focus and measurement of the stop, will admit of more refined measurements, but tenths will do very well.

Having thus laid the foundation, as focussing and the proper use of the stops go hand in hand, I now proceed to that important operation.

The first essential is a very fine ground glass. If the camera has not that it may be improved by oiling, or, better still, by rubbing in a solution of wax in turpentine, and rubbing off as much as possible. For very fine work a good plan is to cement with Canada balsam a microscopic glass cover in the centre of the focussing screen, and employ a focussing glass or Ramsden's eyepiece adjusted so that its focus falls exactly on the front of the focussing screen.

If the object in view be such as the copying of a map, whose sharpness to the edge is a *sine quâ non*, the adjustments as to size, positions, &c., may be made with full aperture or a large stop, and then stops smaller and smaller must be put in, and the image examined until the desired result is obtained.

For portraiture, sharpness all over the plate is not necessary, and sharp backgrounds not desirable. Therefore, *f*-4 or *f*-8 should be used,

and in the case of sitting figures, where the projecting knees may be out of focus when the head is in, the swing back should be employed as a means of correction.

It is in landscape work, however, that focussing assumes almost the dignity of a science, and in which, from an art point of view, the use or abuse of the stop may make or mar a picture. Those whose only aim is to produce what are sometimes called topographical landscapes have only simple duties to perform—to ascertain the point from which the most pleasing composition can be obtained, focus sharply any prominent object, slip in stop *f*-32 or smaller, and give the necessary exposure. But pictures, or, rather, photographs, so produced are destitute of that which gives the greatest charm to a landscape—atmosphere; and as the various distances are all almost equally sharp, the unsatisfied eye wanders, like Noah's dove, from point to point without finding a place on which to rest.

The picture-maker, or true photographic artist, has a different end in view. He wants to make a picture in which the eye shall be led to that which is its *motif* and made to rest there, corraled in from wandering, as it were, by the less sharply defined subordinate parts, while a kind of halo of mystery is suggested by the almost imperceptible atmospheric haze, rather felt than seen in the distance. He, too, like his topographical friend, places his camera on the well-studied point of view, and knowing that the effect of a picture, when confined within the limits of the focussing screen, is often very different from that produced by looking at it in the open, carefully examines it with a large stop, or full aperture. Composition and light and shade satisfactory, and the *motif* clearly defined in his mind, the general effect is carefully studied, and, until he becomes indeed an experienced hand, tried with stops of various sizes, and even by putting the principal points of the *motif* itself more or less out of focus. Far be it from me to recommend the principles of the "fuzzy school," but there *are* subjects that are improved by the removal of razor-edged sharpness.

Working on these lines, the photographic artist will find that the great majority of subjects will be most successfully and artistically photographed with stops varying from *f*-16 to *f*-22, and I may add that I have exhibited pictures that were both admired and medalled, and that the only stop I carry is three inches of hard rubber having at one end an aperture *f*-16, and one *f*-22 at the other.

JOHN CLARK.

FURTHER EXTRACTS FROM THE DAILY AND WEEKLY PRESS ON THE PHOTOGRAPHIC EXHIBITION.

[*Morning Post.*]

Much that is very interesting may be seen at the annual Exhibition of this Society. It comprises a large number of photographic pictures, whose size ranges from the modest "quarter-plate" to such dimensions as seven feet by five feet. They are marked by great diversity of subject, and the different materials and methods by which the prints have been obtained from the negatives add to their variety of effect. Several sets of lantern slides are also on view, together with many cameras of new patterns, some "chromoscopes" for facilitating the inspection of glass transparencies, lenses and tripods, and other paraphernalia appertaining to the profession. *The Story of a Cloud*—a series of five carbon prints—is the result of an ingenious experiment by Mr. Birt Acres, whereby he has secured the changes in the form of a bank of cumulus clouds, from the time when it appeared above the horizon, comparatively insignificant, through its brief epochs of growth, to the moment when its acquired volume is about to drift away again into "thin air." Mr. Acres also exhibits another excellent sky-photograph, as well as some small hand-camera studies at Barnet Fair, more commonplace in character, but very good indeed of their kind. It is not often that dramatic incidents occur when the necessary apparatus is at hand for their record; and Mr. H. J. Godbold is therefore to be congratulated on having obtained such a such a subject as is presented in *A Rocket to the Rescue*, wherein is depicted the timely assistance often rendered by coastguardmen's life-saving gear to the crews of distressed vessels. The figures on the beach are over dark and blurred in detail; but this was, doubtless, owing to no inefficiency on Mr. Godbold's part, but rather to the dull light which evidently prevailed, and to the necessity for a very quick exposure, since the rocket, with its attached line, is visible in mid-air, flying swiftly over the foaming surge to the stranded ship, which lies with its broadside at the mercy of the waves. A wild sea is pictured in the great photograph seven feet long by Messrs. Elliott & Son, which is a carbon enlargement from a whole-plate negative by Mr. Birt Acres. Another excellent work of a similar kind is *Harvesting*, by the Woodbury Company. It is not equal in size to that of Messrs. Elliot, but its length must measure something between four and five feet, and it portrays in a very successful manner a cornfield with a number of labourers busily engaged. *The Rehearsal*, by Mr. Adam Diston, is a humorously arranged composition of two figures, one a man practising upon a huge trumpet, whose portentous magnitude amply warrants the player's gravity of expression; the other his better half, a dame in somewhat eccentric attire, who closes her eyes, perhaps in ecstatic appreciation, or haply slumbers so soundly that she is fortunately spared an infliction "most tolerable and not to be endured." In this and in Mr. Diston's *Highland Smugglers* the grouping is good and the surroundings are appropriate and well arranged. Mr. R. H. Lord's "*How is that?*" wherein a village worthy tests his crony's snuff, is a capital study of rustic character. Mr. J. A. Dumont and Mr. A. G. Tagliaferro contribute some amusing photographs in the same vein, but these essays at picture-making are not uniformly successful. *Cleopatra*, by the Rev. J. A. Rivington, for instance, is good as a photograph, being well manipulated, but, although the accessories are Egyptian in point of decoration, they have a cheap, artificial appearance, and his sitter, although she is dressed appropriately enough, has neither the form nor the features which one connects with the "Serpent of Old Nile." And though the delicacy of the tones of the elastic white drapery worn by the young lady in Mr. J. B. Scott's *An Old Garden* commands admiration, its folds might have been more tastefully arranged. The background, too, on which the title is founded, consists too obviously of a painted screen, displaying a very conventional wall and balustrade. Mr. W. J. Byrne has achieved a well-won reputation for his likenesses of children, and those which he now exhibits are worthy examples of his judgment and skill. Some admirable portraits are sent by Mr. H. H. Cameron, Mr. F. Hollyer, and Messrs. Mowll and Morrison; and there are numerous beautiful landscape studies. Mr. Karl Greger's series of six pastorals, where sheep graze in the meadows or are driven homewards; Mr. B. Gay Wilkinson's *Westminster*, *The Peaceful Evening Hour*, and *The Estuary of the Blyth*; Colonel J. Gale's *Towards Sundown* and *The Incoming Tide*, and Mrs. Main's *Frost and Sunshine*, a set of six varied effects of sunlight on snow, have deservedly obtained the Society's medals; while many more of these transcripts from Nature are equally charming. *In the Pool*, a view of the river and shipping towards evening, by Mr. L. C. Bennett, is especially worthy of mention. Among the best things in the Galleries should also be classed Mr. E. D. Stern's *Scenes in North Africa* and Mr. A. D. Halford's Italian views. Some excellent reproductions of attractive pictures are exhibited by Messrs. Boussod, Valadon & Co., Mr. J. Harold Roller, Mr. H. H. Cameron, and the Woodbury and Autotype Companies. The Exhibition will remain open until November 10, and on three evenings of the week—Mondays, Wednesdays, and Saturdays—it is proposed to have displays with the optical lantern.

[*Globe.*]

In consequence of recent dissensions, into which it is unnecessary to enter, as they are now happily over, some familiar names are missing from the list of exhibitors at the annual exhibition of the Photographic Society. The new management has, however, been well supported, and the exhibition will be found to have many interesting features. The greatest change that has taken place has been the increase of the number of medals to seventeen, in place of the varying number of five to ten which has hitherto ruled. The increase in the number is not to be deprecated, and no fault is to be found with the manner in which they have been bestowed—a point upon which the members of the new Council are especially to be congratulated. In each case the medalled exhibit has special merit, and the medals cover the various sections into which the art is now divided, without any undue bias being displayed towards the prevailing craze among a few, such as in former years has given offence to the general body of the exhibitors. Without attempting to deal with the successful pictures in their order of merit—if they could be held to have any—it may be remarked with pleasure that Mr. Gale, the Meissonier among photographers, occupies a distinguished position; for, though he still prefers to work on a small scale, his pictures are always seen with pleasure and profit, being models of excellence in point of choice of subject, technical skill, and artistic merit. The place of honour is held by an enlargement in carbon, by Messrs. Elliott & Son, of a sea-piece, which is an admirable advertisement for that well-known firm. Then we have medals for prints on rough drawing paper, deservedly given for a series of prints by Mr. B. Gay Wilkinson and Mr. W. Bedford. Another medal is given to Mr. F. Boissonnas for a view of Mont Blanc, taken with one of Dallmeyer's new tele-photographic lenses, which illustrates the latest discovery in photography and points to the great value of Dallmeyer's discovery. In this connexion, too, may be mentioned the medal given to Messrs. Taylor, Taylor, & Hobson, of Leicester. It will be remembered that some time ago the Society took up the vexed question of interchangeable flanges, with a view to remedying a difficulty specially felt by the possessors of a limited number of lenses. The outcome of the discussion of the question was the arrangement of a number of standard flanges; and Messrs. Taylor, Taylor, & Hobson, having adopted the Society's standard, are exhibiting the series, and are rewarded by a medal, which has the additional value of being the only one given for apparatus. Had the judges had another at their disposal, they would doubtless have given it to Beck's new hand camera—the "Frena"—in which the difficulty of the magazine is solved in a very simple and satisfactory manner; likely to create quite a revolution in the "press-the-button" system. There is nothing in the exhibition at all relating to colour-photography—no one is likely to have expected that there would be—but, whether in the matter of amateur or professional work, much will be found to interest and amuse. During the continuance of the Exhibition, there will be the usual lantern nights.

[*Lloyd's.*]

The annual Exhibition of the Photographic Society, Pall Mall East, had preliminary inspection yesterday. An average of excellence ahead of previous collections owes itself in no small degree to a more rigorous standard of selection, necessitating the rejection of a large number of works forwarded. A striking feature is the abandonment of the mere mechanical processes of old, and the importation of a genuine artistic spirit, which can assert itself as potently with a camera as in the art of the engraver and painter. As might be expected, the medallists exhibit some fine work. The work assigned the post of honour, the Tennysonian illustration, *Break, break, break, at the foot of thy crags, O Sea!*—a carbon enlargement from a whole-plate negative by Birt Acres, contributed by Elliott & Son—is a singularly powerful work, the wave breaking near the foreground having peculiar energy of expression, while the light on the horizon suffuses the tremulous sea with singular beauty. Most noticeable is Mr. Henry Stevens's *Meadow Sweet*, for the softness of its tone; and Mr. Yeo's *Blowing Bubbles*, a child's dream of joy ending in disappointment, has very happy treatment, as likewise Mr. J. E. Austin's *Worn Out*, a workman inspecting a clock, and *To Account Rendered*, respectively full of dramatic pose and life. Amongst other medallists are Karl Greger, B. Gay Wilkinson, W. Bedford, J. Gale, A. R. Dresser, F. Muller, J. Harold Roller, W. M. Warneuke, and Mrs. Main. There is a portrait of Professor Herkomer, sent by Gabell's, full of vitality and character, and their *Head of a Boy* has been manipulated with great artistic feeling. One of the interesting examples is the *Story of a Cloud*, five phases of the phenomenon, thirty seconds only intervening between each—an attestation of Mr. Birt Acres' dexterity and close observation. Another contribution fascinating to the scientist will be found in the eighteen photo-micrographs of pure cultivation of bacteria from sewage, by Sir H. E. Roscoe and Mr. Joseph Lunt. Portraiture is well illustrated in Mr. Fred. Hollyer's presentments of Mr. J. M. Barrie, Mr. W. B. Richmond, and Mr. Walter Crane.

[*The People.*]

A New Photographic Terror.—Soirée in Pall Mall.—The *soirée* of the Photographic Society was of unusual interest. The elements of disturbance, which have made things unpleasant for the last year or two, have been got rid of, and, under new management, the Society may be said to have embarked on a fresh career of prosperity. As though to inaugurate the new departure, there was a large attendance, Captain Abney, the President, receiving the guests, in company with Mrs. Abney, other well-known members of the Society doing the honours of the evening. One of the principal items on the programme was, of course, to inspect the show of photographs. This year these are of a very attractive character, the offer of seventeen medals, instead of about half the number, as in previous years, having drawn an excellent collection of photographs. One of the principal exhibits, in point of novelty and interest, was a print of Mont Blanc photographed at a distance of fifty-six miles. This is the first photograph of the kind ever exhibited, and is quite a curiosity. Mr. Dallmeyer, the lens maker, has succeeded, after many failures, in making a photographic lens which screws on to the eyepiece of an ordinary telescope, and enables a photograph to be taken of whatever can be seen by aid of the telescope, with the same finish and detail as though taken in an ordinary camera. The new discovery, thus placed before the public for the first time, opens up new realms of possibilities for the amateur photographer. The detective camera has already played havoc among the proprieties; but the possibilities of the detective camera are as nothing compared with the photographic telescope, inasmuch as the owner of the detective camera could always be seen, whereas the photo-telescopist may be miles away, or, at any rate, concealed at a distance. Seaside "spoonies" and bathing ladies will have to be mindful of probable pictures taken from the houses on the front.

[*Graphic.*]

The Exhibition of the Photographic Society of Great Britain, now on view at the Gallery in Pall Mall East, is quite as comprehensive and interesting as any of its predecessors. It does not appear that any scientific discovery likely to lead to fresh developments of the art has been made during the last year; but most of the works show complete mastery of the methods employed in their production, and a fair proportion bear evidence of artistic taste in selection of subject and arrangement. Landscapes, as usual, form the largest and most satisfactory portion of the display. A series of eight wooded river scenes by Mr. W. Bedford, together with fulness of tone and delicacy of detail, have pictorial beauty of composition, a point of view from which the materials of the subject harmoniously combine having been in each case chosen. The same distinguishing merits are to be seen in Colonel J. Gale's luminous little study, *The Incoming Tide;* in Mr. B. Gay Wilkinson's *The Silver Strand*, and in Mr. W. Wainwright's spacious views of *The Matterhorn* and *Zermatt Valley*. There are some capital examples of instantaneous photography, particularly a well-defined group of flying pigeons, by Mr. F. Blake, and five photographs showing the changes of form of a bank of cumulus cloud in less than half a minute, by Mr. Birt Acres. In a sea-coast view, seven feet long, enlarged from a negative of Mr. Acres, by Messrs. Elliott & Son, the momentary aspect of the breaking waves and moving sky is recorded with convincing fidelity, but the unrelieved blackness of the shadowed rocks in the foreground detracts something from its value. Among the most artistic things in the collection are a series of portraits of well-known men, by Mr. F. Hollyer. The half-lengths of Mr. Burne Jones, Mr. Andrew Lang, and Mr. G. F. Watts are especially good works, they are all naturally posed, and admirably fulfil the requirements of pictorial art as regards balance of light and shade, and harmony of line. Other good examples of photographic portraiture are Mr. F. Downer's gracefully composed group of *Lady Mary Lloyd and Child;* a characteristic half-length of *Professor Herkomer*, by Gabell & Co., and several lifelike heads of children by Mr. H. Yeo. Good reproductions of many well-known pictures are contributed by the Woodbury Company, the Autotype Company, Mr. H. H. Cameron, and MM. Boussod & Valadon; and the valuable service that photography can render to science is shown in several anatomical studies by Mr. T. Chartera-White, and in a series of eighteen photo-micrographs of *Bacteria from Sewage*, by Sir H. E. Roscoe, F.R.S., and Mr. Joseph Lunt.

Our Editorial Table.

Die Photographische Camera und die Momentapparate.

By Dr. J. M. Eder. Halle a. S.: Wilhelm Knapp.

This, the second volume of the *Ausführliches Handbuch der Photographie* treats in detail of probably every known variety of shutter, camera, stand, used in time and instantaneous photography, apparatus for photogrammetry, solar and other kinds of enlarging, telephotography, &c. Its descriptions are full and exhaustive, and, it need hardly be said, are marked by accuracy and clearness. The volume, which consists of over 400 pages, has nearly 700 explanatory illustrations, which alone constitute a feature of great value in a work of this kind.

Brun's Colours.

Messrs. Schwarz & Co., Dashwood House, E.C., have submitted a box of Brun's glossy transparent colours, which we have tried on photographs both on paper and glass, this latter embracing opals and lantern transparencies. These colours are semi-fluid or viscous, and are transparent; therefore they lend themselves admirably to their application to photographs, which they colour without destroying the details, thus ensuring in the case of portraits the preservation of the likeness and drawing. They are easily applied, dry quickly, and may be applied a second and third time to any part needing strengthening up. They are put in small bottles, each bearing its appropriate label, and in boxes containing twelve and twenty-four colours respectively. In the hands of any person of taste very pretty effects can easily be obtained with them.

"Imperial" Opal Plates and Lantern Plates.

The Imperial Dry Plate Company, Limited, Cricklewood, are now issuing opal bromide plates for development by ferrous oxalate and cognate developers. Having tried them, we find that they are highly sensitive, develop clearly, and give good tones. The material is pot opal, finely ground on one side.

We developed some of the lantern plates with iron, amidol, pyrogallol, and hydroquinone respectively, and found them give good results with each of them. The tones, of course, differed with all these.

Under the designation of the *Practical Photographers' Label Book*, Messrs. Percy Lund & Co. have issued a nice and comprehensive collection of useful labels alphabetically arranged, gummed, and perforated. They embrace the names of everything required in photography.

PATENTS COMPLETED.

The Preparation and Employment of Aromatic Amido Compounds as Developing Means in Photography.

No. 15,434. Julius Hauff, Feuerbach, near Stuttgart, Germany. *September* 3, 1892.

The amido phenols, such as p-amido phenol and the two p-amido-cresols, which have been so highly praised of late as developing means for photographic purposes, have the defect that they are so slightly soluble as to necessitate for their use a recourse to caustic alkalies, which are in many ways unsuitable in the practice of photography.

The use of caustic alkalies is likewise needed for the development of the photographic image with p-phenylene-diamines, the use of which is protected by German Letters Patent, No. 46,915, dated August 1, 1888, but has now been freely given up, as great inconvenience resulted from the use of caustic alkalies.

I have remedied these defects by alkalising the amido group, through which I obtain in the p-amidophenol such a solubility as will allow the exclusive use of carbonates of the alkalies, while in the phenylene-diamine I not only obtain a greater solubility, but increase the developing power in such a manner as to allow of the use of carbonates of the alkalies.

For the development of photographic images the following compounds are used :—

I. Alkalised amidophenols of the composition $\begin{matrix}-OH \\ -NR_1R_2\end{matrix}$ amongst which are the mono- and di-methyl-(ethyl-) derivatives of

1. p-amidophenol,
2. o-amido-m-cresol,
3. m-amido-o-cresol,
4. m-amido-(v-)m-xylenol,
5. m-amido-p-xylenol,
6. o-amido-(v-)o-xylenol,
7. o-amido-(s-)m-xylenol.

The alkalised amido-phenols have a solubility of 3 per 100 and, have moreover, as compared with the ordinary amido-phenols, much more energetic properties.

The following solutions are prepared as being most suitable,

Solution A.

Metol (methyl-p-amido-m-cresol	1 gramme.
Sulphite of soda	10 grammes.
Water	100 ,,

Solution B.

Potash	10 grammes.
Water	100 ,,

For use, two or three parts of the solution A are mixed with one part of the solution B.

It is obvious that soda, as well as sulphite of potash, may be likewise used. The following is the best concentrated developing agent ready for use.

Metol	2·5 grammes.
Sulphite of soda	25 ,,
Potash	12·5 ,,
Water	100 ,,

For use it is diluted to from five to eight times its volume.

II. Alkalised diamines. Mono-, di-, and tetramethyl- (ethyl-) derivatives of

1. p-phenylene diamine,
2. p-toluylenediamine,
3. p-xylylenediamine,
4. α-β-napthylene diamine,
5. α-α-napthylenediamine.

The alkalised phenylenediamines are distinguishable by their extraordinary solubility, and have the property of developing the photographic image with carbonates of the alkalies. The durability of the solutions is very great.

For developing purposes the following mixture is used :—

1 gramme dimethylphenylenediamine,
5 grammes sulphite of soda,
5 grammes potash,
100 grammes water.

It is a phenomenon worthy of notice that the alkalised p-phenylene-diamines develop with sulphite of the alkalies without the use of potash.

Having now particularly described and ascertained the nature of this invention, and in what manner the same is to be performed, I declare that what I claim is :—The use of the following alkalised amido-compounds for the development of photographic images in layers containing halogene silver.

I. Alkalised amido-phenols of the composition $\begin{matrix}-OH \\ -NR_1R_2\end{matrix}$ amongst which the mono- and di-methyl- (ethyl-) derivatives of

1. p-amidophenol,
2. o-amido-m-cresol,
3. m-amido-o-cresol,
4. m-amido-(v-)m-xylenol,
5. m-amido-p-xylenol,
6. o-amido-(v-)o-xylenol,
7. o-amido-(s-)m-xylenol.

II. Alkalised diamines. The mono- and di-methyl- (ethyl-) derivatives of

1. p-phenylenediamine,
2. p-toluylenediamine,
3. p-xylylenediamine,
4. α-β-napthylenediamine,
5. α-α-napthylenediamine.

Improvements in Photographic Cameras.

No. 15,657. Fox Shew, 88, Newman-street, Oxford-street, Middlesex, and Lorenzo Cecil Vaughan Henry, Kylemore Castle, County Galway, Ireland.—*September* 3, 1892.

The invention has for its object improvements in photographic cameras, whereby lenses of shorter focus than that used with the camera in its normal or extended condition can be used and accurately focussed, and whereby the front of the camera can be tilted and swung within certain limits, thereby obtaining, amongst other advantages, that of a rising front or swing back.

The invention relates to that class of camera in which the back and front are connected by bellows, and in which the front is adjusted and fixed between hinge-bound side wings hinged to the back of the camera, thus obtaining rigidity in the camera when in use, and at the same time enabling it to be folded readily into a small compass.

According to the present invention, the hinge-bound wings are slotted longitudinally, and the slots are carried past the holes fitting over the lens when the camera is folded. One method by which this is effected is by the use of metal or other guides or rods, mounted with capability of being slidden across the holes, in order to continue the slots, but which, when the camera is folded, are pushed back, so as to leave the holes clear for the passage of the lens therethrough. Other methods of continuing the slots across the holes can, however, be employed.

In some cases we dispense with the lens holes in the wings, and carry the slots from one end to the other thereof, in which case the lens is removed from its fixing before folding the camera.

Thus the front of the camera can be adjusted in distance in relation to the back, so as to enable various lenses to be used therewith and accurately focussed and fixed by means of clamping-nuts or screws attached to the front of the camera, and passing through the said slots. By this arrangement the front of the camera can be tilted and swung within certain limits, and securely fixed in such position by the clamping-nuts or screws, thereby obtaining similar results to those of a double swing-back camera.

The invention also relates to a new method of raising the front of the camera, which is applicable to the description of camera above referred to, as also to other kinds of cameras.

For this purpose the front of the camera is formed with a frame or false front, which is provided with guides to receive a sliding lens board carrying the lens and the front of the bellows, a screw and nut or other suitable means being employed to raise and lower the said lens board.

In some cases we provide the sliding lens board above described with an additional board sliding in horizontal guides mounted on the said lens board. When employing this particular form of front, the lens is mounted in the additional sliding board. This will enable the lens to be moved in a horizontal as well as in a vertical direction.

The claims are :—1. In cameras of the character herein referred to, the slotted hinge-bound side wings, and the combination therewith of means for guiding the camera front in said slots, and for fixing said front at different distances from the back, substantially as herein shown and described, and for the purpose stated. 2. In cameras of the character herein referred to, the longitudinally slotted side wings, and the combination therewith of means for guiding the camera front in said slots, and for fixing said front at different distances from the back and at various angles therewith, substantially as herein shown and described. 3. In cameras of the character herein referred to, when employing perforated side wings to fit over the lens, the combination with such perforated side wings of longitudinal slots on each side of the perforation, and of movable means for continuing said slots across the perforation, substantially as herein shown and described, and for the purpose stated. 4. The combination with cameras of a sliding front whereby the lens is capable of being raised and lowered, substantially as herein shown and described. 5. The combination with cameras of a front provided with frames so guided as to be capable of being moved at right angles to each other, one of such frames carrying the lens, so that the latter can be moved either in a vertical or horizontal direction, or in both directions, substantially as herein shown and described. 6. In cameras in which the front and back are connected by a bellows body and held in position by hinge-bound side wings, the construction of such side wings with longitudinal slots, and the combination therewith of means for fixing the movable parts of the camera at any desired position in such slots, substantially as herein shown and described.

Improvements in the Art of Producing Coloured Photographs.

No. 5597. James William McDonough, 1124, Monadnock-buildings, Chicago, United States of America.—*September* 10, 1892.

My invention relates to the production of coloured photographs, and may be carried out in several different ways, one or two of which I will now set forth :

I take a plain glass plate and flow or cover it with a coat of varnish, or similar material which will dry tacky. I then dust the plate with a mixture of colours composed of fine or powdered particles containing the colours desired, and thus I obtain a coloured surface composed of particles lying side by side which have the properties of stippled colours instead of the properties of a true mixture of pigments.

In order to get these coloured particles I may use powdered glass, transparent pigments, gelatine, resin, or shellac, stained by aniline dyes, &c. The glass colours, after having been dusted upon the surface of the dry plate, may be melted into the plate, by fire, if desired.

In the preparation of a glass negative with shellac stained in colours, the plate may be flowed or covered with a plain collodion, to which is added a small quantity of glycerine, so that when the collodion is dry it will remain tacky enough to retain coloured shellac dust in a single layer. I then take a sufficient quantity of clean white shellac, dissolved in alcohol, to which I add aniline colours, say, for one lot, red and yellow colours in such proportions that the result will be a red which, when viewed by transmitted light in thin layers, will cut off or absorb as much green, blue, and violet as possible, or which, in other words, will transmit as far as possible a pure red. Another lot is coloured with as pure a green as may be formed by mixtures, adding

yellow to absorb blue. Another lot is coloured blue. As the mixtures of colours formed in this way by red and green do not form a bright yellow, I may use, in addition, another lot coloured as near the yellow of the spectrum as possible. These lots, after being thus coloured, are allowed to dry, forming coloured masses, which are then reduced to powder by grinding, sifting, &c.

If, now, proper proportions of red and green are mixed, a nearly black mass will be formed, and, if proper proportions of red, green, yellow, and blue are mixed, a mass will be formed that is nearly black; but if this same mixture is dusted, or thinly spread, upon the prepared surface, it will reflect or transmit a mixture of all these colours, which will be white in proportion to the purity of the colour, cleanliness of the mixture, and the quantity of light transmitted or reflected. The glycerine may be washed out, so that only the coloured particles in the masses in which they are arranged remain. When viewed under the microscope, the white surface is seen to be composed of a multitude of different coloured particles lying side by side, and separated by small distances.

By subjecting the plate thus prepared to just sufficient heat to melt the shellac, two results are obtained; first, the powdered particles melt, and fill the gaps, forming a surface which, when viewed in the microscope, resembles a window formed of a mosaic of small coloured pieces, each adjoining the other, while, if the heat be carried further, the edges melt into each other, and further mixtures of colours are obtained; second, the surface of the plate which, before heating, reflects all the colours, and resembles the surface of ground glass, or glass covered with a white powder, in what is termed a matt surface, becomes, under the influence of heat, transparent by the flattening of the particles. This result may also be obtained in a measure by covering the surface with varnish, so as to make it smooth.

A plate formed in this way upon any suitable material may be flowed or covered with such sensitive compounds as are used in taking photographs.

Instead of treating the glass plate with a coat of varnish or similar material which will dry tacky, and then dusting such plate with a mixture of colours, as above described, I may take a support of plain glass, celluloid, paper, or other suitable substanee, upon the surface of which is a sensitive photographic coating, preferably forming what is known as an orthochromatic dry plate. This may be rendered tacky by immersing in water or diluted glycerine. If preferred, however, the plate may be used before it gets quite dry in the course of its manufacture. I dust the plate either while it is somewhat moist in the course of its manufacture, or after it has become tacky, as above explained, with a mixture of colours composed of fine or powdered particles containing the colonrs desired. The particles, however, may, if preferred, be applied in other ways so long as the same result is secured. I thus obtain a coloured surface composed of particles lying side by side which have the properties of stippled colonrs, as above explained. In the latter of the methods of forming the plate above described, after the colours are applied, the surface may be flowed with a thin coat of gelatine, which will penetrate the spaces between the coloured particles, or the ground and coloured particles may be coated with gelatine before applying them to the tacky surface by mixing them with a small quantity of dissolved gelatine and regrinding them, according as a matt or smooth surface is required.

The process of producing the effect called colour above described is by absorption of light; but, inasmuch as colour effects may be produced by refraction, dispersion, or diffraction of light, I do not mean to limit myself to absorption only as the means of producing them.

The photographic plate thus obtained, consisting of coloured particles applied to its sensitive surface, may be exposed to the action of the light from the object to be photographed, through a camera, in such manner that this light will pass through the coloured particles and affect the sensitive film, thus producing a latent image of the object.

The plate may then be developed by the use of the so-called alkaline developer, so that the coloured particles will adhere to the surface, which is penetrated by the same coloured light as the particles themselves, because gelatine is rendered insoluble in proximity to the silver bromide particles in the sensitive compound where acted upon by light. Thus particles which do not allow the passage of coloured rays, on account of absorption, may be washed off, because as to such particles the gelatine remains soluble. Thus blue rays will cause blue particles to remain as an image; white light, all the coloured particles in that space acted upon by white light; and all will be removed where black occurs, which does not act upon the photographic film. After the development, the picture may be treated with thio-sulphate of soda to remove the sensitive compound not acted on by the light and developer. By thus developing the plate, a picture composed of the particles of silver and the coloured particles remaining on the plate after the development is produced.

The use of orthochromatic dry plates and coloured screens before the camera for the purpose of sifting light and regulating the action of different colours upon the film is too well known to require explanation. I will merely add that the particles are dusted, spread or placed upon the plate in such proportions as to produce a white or transparent surface.

It is obvious that many variations may be made in the details of my invention without departing from the spirit thereof.

The claims are:—1. The process of preparing photographic plates, which consists in covering them with coloured particles, and then applying a sensitive compound to them, substantially as and for the purpose set forth. 2. The process of preparing photographic plates, which consists in covering them with coloured particles, then subjecting them to heat, and then applying a sensitive compound to them, substantially as described. 3. A plate for photographic purposes having upon its surface a layer of different coloured particles lying side by side, and in such proportions as to produce a white or light-coloured transparent surface, to which may be applied a sensitive compound, substantially as described. 4. A plate for photographic purposes formed of glass or other suitable material of any colour, a layer of different coloured particles spread thereon, and a film of sensitive photographic compound spread over the particles, substantially as described. 5. The process of preparing photographic plates, which consists in applying a sensitive compound to them and then covering them with coloured particles, substantially as described. 6. The process of preparing photographic plates, which consists in applying to their sensitive surface particles of glass or other substances which show colours by absorption, refraction, dispersion, or diffraction, substantially as described. 7. The process of preparing photographic plates and pictures, which consists in applying a sensitive compound to them, covering them with coloured particles lying side by side in such proportions as to produce a white or light-coloured transparent surface, and then washing out such particles as are not acted upon by light, substantially as described. 8. A plate for photographic purposes, having a sensitive surface to which is applied a layer of different coloured particles lying side by side and in such proportion as to produce a white or light-coloured transparent surface, substantially as described.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 10	Darlington	Trevelyan Hotel, Darlington.
,, 10	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 10	Lantern Society	20, Hanover-square.
,, 10	Norfolk and Norwich	Bell Hotel, Norwich.
,, 10	North Middlesex	Jubilee Hall, Hornsey-road, N.
,, 11	Derby (Annual)	Smith's Restaurant, Victoria-st.
,, 11	Manchester Amateur	Lecture Hall, Athenæum.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 29,—Mr. J. Barker in the chair.

MISS CATHARINE WEED BARNES ELECTED AN HONORARY MEMBER.

Mr. A. HADDON said that he had no doubt the proposal he had to make would meet with the approval of the meeting; this was, that Miss Catharine Weed Barnes be elected an Honorary Member of the Association. Miss Barnes had given a certain amount of time to the preparation of the paper she had recently brought before them, and he thought it would be some reward to her to elect her an honorary member.

Mr. F. A. BRIDGE seconded the motion, which was carried unanimously.

The following question from the box, "Will some one please give a formula for a really rapid gelatine emulsion, and the best method of breaking it up, washing and filtering it in large bulks?" was postponed till the next meeting.

THE EXPANSION OF AMMONIA SOLUTION.

Mr. HADDON observed that he considered it the duty of every member to correct errors provided they were supposed to be based on scientific data. In many books of science there were errors which it was unfortunate should be copied and become current knowledge. There was an article by Mr. J. Cadett in the first number of his firm's monthly magazine, *Dry Plates*, which gave a certain amount of information with regard to ammonia, and especially as regarded its dilution. Now, most people knew that, if one took a pint of alcohol and mixed it with a pint of water, one did not obtain two pints by measure but something less. It was the same with sulphuric acid. The passage in Mr. Cadett's article to which he took exception was as follows:—"Ammonia has the remarkable property of having the same bulk, *per se*, in all solutions of various quantities of water—that is to say, it neither expands nor condenses in consequence of combining with, or being diluted by, water, in which it differs essentially from the fixed alkalies and the liquid acids." That (said Mr. Haddon) was a mistake. Most probably Mr. Cadett himself was not responsible for the statement, but had copied it, and not being able to verify the quotation had given it to the world as a fact. According to Watts' *Dictionary of Chemistry*, one volume of water, by absorbing 505 volumes of ammonia, occupies 1·5 volume of the sp. gr. ·9; and this, when mixed with an equal bulk of water, yields a liquid of sp. gr. ·9455. Whence it appears clear that ammonia expands on dilution, although it does not actually seem to have been proved by experiment. Therefore he thought it might be worth while to make the experiment and satisfy himself as to whether ammonia when diluted was really of the same bulk, or whether there were any changes in one direction or in another. On a large glass tube he accordingly blew two bulbs; the measure of capacity of the lower part of the tube was 97 c.c., which he indicated by a scratch, another scratch being made to indicate a capacity of 116·5 c.c. Having filled up to the first scratch with distilled water by means of a funnel, he then poured into it the strongest ammonia—most probably the ordinary ammonia ·880. In order to make sure that the temperature was uniform, the tube was immersed for a quarter of an hour in water at 19° C., and was adjusted so that the meniscus exactly corresponded with the upper scratch on the glass

The water and ammonia being mixed, the solution was tested for increase of volume, and, in order to make sure that temperature had nothing to do with it, the tube was again immersed in water at 19° C. To ascertain the percentage of increase in volume he poured into the small tube, before sealing it on to the larger, 5 c.c. of water, and found that they occupied exactly 24 c.c. in length of the tube, the increase in length thus occupying 3·3 c.c., which comes to about ·37 per cent. increase in volume. Mr. Cadett had founded certain conclusions on the assumption that there was no change when ammonia was diluted; so it would naturally be that those calculations were not true. For instance, as to Mr. Cadett's statement that seventeen grains of actual ammonia were dissolved in a tenth of a gallon of water for a change of ·001 in the specific gravity of the solution, Mr. Haddon quoted two examples from *Watts's Dictionary of Chemistry* to prove that the latter and Mr. Cadett differed. Ammonia (said Watts), containing 36 per cent. of real ammonia, has a specific gravity of ·884. Subtracting this number from 1·000, and neglecting the decimal point we get Mr. Cadett's strength number, 1·000 – ·884 = ·116. 116 × 17 = the total number of grains of ammonia in a tenth of a gallon of water = 1972 grains. But taking ammonia solution, specific gravity ·921, which, according to the same authority (Watts), contains 18 per cent. of real ammonia, and following the same rule, 1·000 – ·931 = ·069, 69 × 17 = 1173 grains per tenth of gallon of water. This number, according to Mr. Cadett, ought to be 986 grains, a difference of about 16 per cent. of real ammonia. Some time back, when studying the best method of obtaining ammonia of a constant strength, he prepared a curve on squared paper, showing the relation of percentage strength to specific gravity, and, instead of being a straight line, it was a decided curve, showing that in all cases the specific gravity of a diluted solution was less than it ought to be if there was no change in volume. It was because he thought such a mistake ought not to be spread among photographers as a fact that he undertook the above experiment. He was of opinion that few men (even scientists) knew of the expansion of ammonia on dilution.

PHOTOGRAPHS BY MR. SHAPOOR N. BHEDWAR.

Mr. Snowden Ward passed round five large platinum photographs showing the initiation of Mr. Bhedwar's son as a Parsee priest. It was a subject that had never been pictorially treated up to the present time. Two Parsee priests were the models, and the vessels shown in the pictures were the actual vessels used in the temple, so that there was absolutely nothing of a "studio character" about the pictures except the backgrounds. Mr. Ward stated that the *Illustrated London News* would reproduce the pictures in an early number, and would also give a description of the rite of initiation.

GELATINE PLATES FOR LANTERN SLIDE WORK.

In the absence of the author, Mr. George T. Harris, a paper on the above subject was read by the HON. SECRETARY (Mr. R. P. Drage) [see page 5 of the LANTERN SUPPLEMENT]. At its conclusion,

Mr. W. E. DEBENHAM said he could see no advantage in the use of two kinds of gelatine, and thought the use of a hard and a soft kind a superstition remaining from the early days of gelatine plate-making. The preparation of the emulsion would be simplified by the use of one gelatine. He himself had made the fastest emulsions with hard gelatine throughout.

Mr. J. S. TEAPE remarked that Mr. Harris stated that he had obtained no change of colour with the silver intensifier; but he (Mr. Teape) had found that, unless the image was black to start with, he never remembered intensifying without a change of colour. Then, as regards fixing, he never used the combined fixing bath. Plates after development were not necessarily yellow. He always kept a clear hypo bath for lantern work.

The Chairman showed some albumen negatives about thirty years old which he thought might interest some of the younger members who had never seen such films. He drew attention to their qualities of fineness and clearness. In reply to a question, he said the exposure required was four to five times that of wet collodion. Dust was a very great difficulty—in fact, it was one of the nuisances of the process.

Mr. W. H. BARNES said the negatives showed less grain than those otherwise produced; but, all the same, he did not think it a practical process.

Several members having described the boxes they had devised and used for drying purposes, a vote of thanks was passed to Mr. G. Harris for his paper. During the evening, Mr. Haddon and Mr. Snowden Ward were similarly thanked for their interesting communications.

Hackney Photographic Society.—September 27, Mr. Walter Potter presiding.—The Hon. Secretary announced that the judges in the forthcoming competition would be Captain Abney, Colonel J. Gale, and Mr. Ralph W. Robinson. Works were shown by Messrs. Pollard, Nunn, Dean, and the Hon. Secretary. From the question box: "Does bromide paper lose rapidity with age?" Mr. Barker had used some two years old with little loss of rapidity. Mr. S. J. Beckett had used some four years old. Another question was: "Can I use amidol without bromide, and can I over-develop with it?" The HON. SECRETARY said he had used it without bromide, and had found it work satisfactorily. Mr. SODEAU said it was possible to over-develop with amidol. A third question was: "Should chloride of gold be kept alkaline in solution?" Mr. SODEAU said it should be slightly acid, but it was rarely ever done. The Hon. Secretary then gave a lantern lecture on his holiday in the Isle of Man (in conjunction with Mr. Dando) during which over eighty slides were shown.

Leytonstone Camera Club.—The opening night of the winter season was held on the 1st inst, with an address by the President, Dr. W. Pickett Turner, who opened by complimenting the Club on the position it had made, and the strength it had attained, the muster being ninety-six members. He next went on to the science and art of photography, dealing with the chemistry, first giving, with the aid of the black board, the various formulæ of the various salts and compounds used in photography, explaining that the rational changes were not chemical but molecular, advising beginners to study orthodox chemistry, first taking Roscoe or Fownes as their Bible. He next went on to the science of optics, and then touched on the art side of photography, and explained that manipulative dexterity can be acquired by practice, and how highly important for success it was that the best apparatus that could be afforded should always be had, particularly the lens, which was a *sine qua non* to good work, explaining that they were the cheapest in the long run, as they were always worth their money. The collodion process was next touched upon, and he was of opinion that, notwithstanding the many advantages of the dry plate, collodion still held its own for transparency and lantern slides. There was, he said, a branch of photography which had almost died out, but was now coming to the fore again, he alluded to stereoscopic photography; he thought it one of the highest branches, and gave the most charming results, and strongly advocated it being taken up by the members. In his closing remarks, the coming exhibition was alluded to, and he particularly urged the importance of all members exhibiting, and to dispel that feeling of "It's no use, So-and-So does much better work than I," explaining that it was just as likely for a good half-plate to take a medal as a 12×10. Sample packets of the Ilford Printing-out Paper were next distributed, and the evening closed with a hearty vote of thanks to the President for his highly interesting and instructive address, which had been attentively listened to by about forty members.

Aldenham Institute Camera Club.—From the very constitution of our club, limited as it is to members of the Institute, a large annual increase in its members cannot be expected, but during the past year four gentlemen have joined our ranks, which makes a present membership of fourteen. Though the numbers have been small, the loyalty and enthusiasm have been great, as the following particulars will demonstrate. During the year twenty meetings have been held, with an average attendance of 12·5. Six of these meetings, which were thought to be of general interest, were thrown open to the Institute, the result being an average attendance of 24·3. At the competition held in January, fifty-four prints and twenty-four lantern slides were submitted for consideration, the Judge's award being as follows:—Architecture, Mr. G. E. Harris; landscape, Mr. H. J. Redfern; seascape, Mr. G. E. Harris; lantern slides, Mr. G. E. Harris. Our Secretary also gained the medal kindly presented by Mr. James Robertson, our President, for the best print entered for competition. On April 30 an exhibition of the Club's work was held; 105 pictures were on view, including a few kindly lent by Messrs. Nesbitt & Co. The experiment was fully justified by the amount of interest evinced. We hope during the present season to organize a larger exhibition. Monthly excursions were arranged by the club during the summer, the places visited being Leigh and Southend, Burnham-on-Crouch, Hayes Common, Keston and Down, and Broxbourne. Although bad weather almost invariably accompanied us, the outings always proved highly enjoyable. At the late Photographic Convention held in Edinburgh, our Club was represented by Messrs. Redfern and W. Pringle, from whom we hope to receive ere long a narration of their adventures.

Harlesden and Willesden Photographic Society.—October 4, Mr. J. Naylor in the chair.—A lengthy discussion took place upon printing processes for various negatives. The PRESIDENT commented upon their high sensitiveness in dull weather. An excursion to Windsor was arranged.

Putney Photographic Society.—October 3, Dr. J. E. Farrar in the chair.—The following five gentlemen were unanimously elected members, viz., Messrs. Beatie, Blake, Noble, Ward, and Woolnough. Mr. Gorin showed negatives on the Sandell plate, taken under very varying circumstances with uniformly good results; he also showed the effect caused by interleaving exposed plates with the paper usually sold for this purpose, the images of the sheets were imprinted on the negatives, of course with disastrous consequences. It was generally agreed that it was best to pack exposed plates film to film direct, and to jamb them tightly in the boxes, so as to prevent play in any direction. Mr. POOLE said that in his hands spirits of turpentine applied with a soft rag formed an efficient and convenient reducer of dense negatives, lantern slides, and opals. For local or general treatment, he stated that it had advantages over methylated spirit similarly applied. Mr. Zachariasen showed a number of prints illustrating a series of experiments carried out by him to ascertain the effects of varying treatment of gelatino-chloride papers. The prints showed the difference between thorough washing and merely rinsing, between a strong and a weak fixing bath, between acid and alkaline fixing baths, &c. Three brands of paper were each toned in five different toning baths. The results of altogether 120 different experiments were shown; the characteristics of each paper, bath, and detail of manipulation were pointed out and summarised. He also described some experiments undertaken to find a suitable developer for snap-shots taken on a recent tour in Norway, and which all suffered, to some extent, from under-exposure. After the pyro formula sent out with the plates, he tried rodinal, eikonogen, hydroquinone, and amidol, singly or combined, as advocated by the champions of each; all, however, with more or less unsatisfactory results. He then reverted to pyro and ammonia, but made up in the following proportions, viz., pyro, four grains; bromide of potassium, one grain; ammonia (·880), three minims to the ounce of developer; to which were added two minims when the image was fairly up. This developer worked very satisfactorily, and was finally adopted, the results being above expectations. This was confirmed by the experience of Mr. Gorin, who had used it for snap-shots, taken on Edwards' instantaneous isochromatic plates, on his recent tour in Morocco. Mr. Zachariasen's negatives were taken on Paget 50-times plates, the favourable opinion of which was confirmed by Mr. Blake. Messrs. Beckett "Bynoe" printing frames were exhibited in various sizes, and were favourably commented upon by members who have had them in use for some time.

Richmond Camera Club.—Report and Balance Sheet for the year ended August 31, 1892:—In presenting their second Annual Report the Committee are glad to be able to congratulate the members on the continued and increased success of the Richmond Camera Club. Though not strong in point of numbers compared with some other Photographic Societies, the membership shows a steady increase, twenty new members having been enrolled during the past year, while only four have resigned. Amongst the recruits are some of the best-known local amateurs. Weekly meetings have been held throughout the year, and those during the winter months were very well attended. The experiment of keeping up the meetings during the summer was scarcely justified by its result, the meetings, which were

for the most part informal, having been but thinly attended. The demonstrations given and papers read at the meetings were of a very varied and interesting character, and the practical utility of the Club is traceable in the marked improvement in the general quality of members' work, especially, perhaps, in their lantern slides. Two important steps were taken during the year in the establishment of a library and the acquisition of an optical lantern. Several members have presented books to the library, which already contains most of the works in general use on photographic subjects. The cost of the Club lantern, an excellent single instrument by Otway, with the necessary accessories, was almost wholly defrayed by the contribntions of members. The Club is now affiliated to the Photographic Society of Great Britain, under the scheme lately established by the latter Society. Two delegates have been appointed to represent the Club at affiliation meetings. The cordial thanks of the Club are due to all those who have contributed to make the past year's working so satisfactory and so pleasant to review, and especially to the various firms and gentlemen who have given demonstrations, and to the photographic and local press for so freely extending the hospitality of their columns to the reports of the proceedings of the Club.

Liverpool Amateur Photographic Association.—The President (Mr. W. Tomkinson) occupied the chair, and there was a very large attendance, attracted, no doubt, by the announcement that Mr. George E. Thompson would deliver his new lecture, entitled *Hill-top Cities of Etruria*, illustrated by lantern slides from negatives taken by the lecturer during the spring of this year. Mr. Thompson holds such a high position in the estimation of the members, both as a lecturer and as a photographer, that he is always sure of a crowded audience. After the election of seven new members, Mr. Thompson commenced his lecture, of which the following is a synopsis. Orvieto: Its famous cathedral; its old gates, and precipices. Viterbo: Ancient walled town; fountains, buildings, and monastery of La Quercia; grand old garden. Excursion to Caprarola. Montefiascone, and down to Lake Bolsena; basaltic columns; old town. Orte, on the Tiber. Narni: Ruined bridge; quaint streets. Segni: On its crags. The monastery of Monte Cassino. Corneto: Etruscan tombs 2400 years old; museum; sarcophagi; Etruscan pottery. Carrara: Marble quarries; grand scenery of the Marble Mountains; a marble Venus come to light. The lecture was most interesting throughout, and the slides were of the highest quality. This was particularly noticeable when the pictures of the Carrara marble mines were being shown. The enormous extent of these considerably surprised most of the members, and the beauty of the Marble Mountains was expressed in the photographs with wonderful realism. At the close of the lecture, Mr. B. J. Sayce proposed a hearty vote of thanks to Mr. Thompson, and this was carried with acclamation. On the motion of the lecturer, a cordial vote of thanks was then given to Mr. F. Anyon for the admirable way in which he had worked the Society's new lantern. It is a matter for congratulation, and was much commented on, that, although the large room was crowded for about two hours, the temperature and atmosphere were most comfortable and agreeable throughout, thanks to the efficient ventilation and the electric light.

Liverpool Camera Club.—September 28, Mr. W. Hayward in the chair.—The paper for the evening was furnished by Mr. T. Edwards, who had for his subject *Hints on the Manipulation of the Lantern*. Mr. Edwards had kindly brought his own lantern, which he described fully, and showed many improvements which his large experience had suggested. Mr. Edwards then proceeded to explain the working of the lantern, describing every particular and conveying many useful hints to the members. The lecturer afterwards passed a number of slides through the lantern, thus bringing to a close an interesting and instructive paper. The first smoking concert of the Winter Session is to be held in the club rooms on Wednesday, October 12.

South Manchester Photographic Society.—September 26, annual meeting, Mr. W. I. Chadwick in the chair.—Messrs. Holmes, Hunt, and Norris were elected members. The Hon. Secretary then read his report for the present session, which was as follows:—"The officers have to congratulate the members on the progress made by the Society since its formation in February of the present year, the number of members now enrolled being thirty-three. The financial position of the Society was very satisfactory, there being a substantial balance to its credit." The report then went on to describe the meetings and the various papers read, among them being *Photography by Artificial Light;* this was followed by a practical demonstration, *Platinum Printing*, by the Hon. Secretary (M. W. Thompstone); *Magic Lantern Matters*, by the Chairman (W. I. Chadwick), &c. A good deal of attention had been devoted to stereoscopic work, and some very beautiful transparencies were shown at several of the meetings. Discussions had also arisen from questions as regards developing, printing, toning, &c. At the popular meeting held in March, a paper was given on *Holiday Reminiscences, including a Trip to the Isle of Wight*, by Mr. W. I. Chadwick, which was very well attended by members and their friends. The outdoor rambles had been fairly successful, those which have been held being well attended. The Hon. Treasurer's balance-sheet was then presented and passed. The election of officers for the ensuing year followed, and after a short discussion was decided as follows:—*Chairman:* Mr. W. I. Chadwick.—*Vice-Chairman:* Mr. W. Linnell.—*Hon. Treasurer:* Mr. E. N. Bowden.—*Hon. Secretary:* Mr. M. W. Thompstone. The meeting then adjourned to the large Lecture Hall, where the Hon. Secretary gave a short paper on *Picturesque England*, illustrated with some eighty slides specially selected for the paper. The places visited included the English lake district, the old abbeys of Yorkshire, the River Thames, Devonshire, Cornwall, Derbyshire, concluding with Shakespeare's country. At one part of the lecture some miscellaneous slides and cloud and water effects, snow effects, &c., were introduced.

Port Elizabeth Amateur Photographic Society.—The first annual exhibition and entertainment in connexion with this Society was recently held. The first photographic item on the programme created great interest. It consisted of taking a photograph on the stage by means of a magnesium flash; the development of the negative, the making of a lantern slide, which was then placed in the lantern, and the whole of the wonderful process of development of the latent image was visible to the audience on the sheet in front of the lantern. It should be noted here that this experiment has never been attempted before in this colony; in fact, it has been performed in England but a few times; and when we inform our readers that it was a complete success, it says much for the proficiency of the members of the Society. Mr. D. M. Brown was chosen as the subject to be operated upon in this experiment, and having been placed in position on the platform, his photograph was taken with the aid of a single magnesium flash. After development, Mr. Alcock made the lantern-slide in view of the audience, and having placed the slide with its developing solution in the lantern, the well-known features of Mr. Brown became gradually visible on the sheet. The successful experiment was greeted with well-deserved applause. During the time occupied in the first instance by the development of the negative, the audience had an opportunity of inspecting the large number of perfectly finished photographs which were exhibited in the hall. These were without exception very good, and were all the work of amateurs, and would have done credit to any London studio. After the completion of the lantern-slide development, a display of local views, &c., contributed by members of the Society, took place, and, as lantern slides, would take a lot of beating.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

"COOL WATERS."

To the Editor.

Sir,—I have been away from home or would have replied sooner to the letter of Messrs. Morgan & Co. in your issue of September 23.

I cannot reconcile their statement that they "never suggested or in any way implied that the photograph was by themselves" with the fact that they withheld information as to the authorship, and thereby misled Messrs. Nops & Tarrant (whose letter is in the same number of the Journal), there having been, by their own admission, a ticket attached to the picture when in their window which stated that it was "photographed from nature, and enlarged by J. Vaughan." The ticket itself told only half the truth, for the enlargement merely was Mr. Vaughan's part, the negative, as stated in my previous letter, having been taken by myself, which I am able to substantiate.

Messrs. Morgan & Co. are quite mistaken in supposing that they have a "legal purchased right," to quote their own words, to put their names on prints from negatives which they have purchased. The Copyright Act relating to photographs, of which there is a clear summary by Mr. Le Neve Foster, Barrister-at-Law, in your Almanac for 1869, says: "The absolute property and copyright belong to the person taking the negative on his own account (not so in the case of portraits taken on commission), and even if the author has disposed of his copyright and negative the *purchaser*, in issuing prints from any of his purchased negatives, must *not* place *his* name, initials, or monogram on them, or the name, &c., of any one who did not execute the work." The Act also makes it "penal in any one doing this so as to make it appear that the prints are from the work of some one who in reality did not execute the negative."

I am sorry to trouble your columns with this matter, but do not think it right that such credit as is due for the photograph should be appropriated by persons who had no part whatever in its production. It is not yet too late for Messrs. Morgan & Co. to express some regret for their procedure.—I am, yours, &c.,

Henry Whitfield.

Clifton, October 3.

"THE PHOTOGRAPHER'S RECORD."

To the Editor.

Sir,—Since issuing the first number of our little paper we find that we have adopted a title that was already in use by Messrs. George Mason & Co., the well-known dealers in photographic material, of Sauchiehall-street, Glasgow. We therefore tender Messrs. Mason our apologies, and beg to inform your readers that we have modified the title of our paper, which will henceforth be known as "The Photographer's Record," and will, as before stated, be sent post free to professional photographers on receipt of business card, and supplies forwarded, carriage paid, to secretaries of Societies and dealers in photographic goods for distribution.—We are, yours, &c.,

Elliott & Son.

Photographic Printing, Enlarging, and Dry Plate Works,
Park-road, Barnet, Herts, October 3, 1892.

MR. BERGHEIM NOT A "VIENNA PHOTOGRAPHER."

To the Editor.

Sir,—In the article on "The Photographic Exhibition" in your last issue I am twice mentioned as "J. S. Bergheim, the Vienna photographer." I beg to state that I am simply an amateur of little over three years' standing, and without a studio, and that I happen now to reside the greater part of the year in Vienna.

It may interest some of your readers to know that the "too soft" *Study of a Head* (No. 18) is from an untouched negative, and was taken with an uncorrected single lens, and shows what can be done with such simple means. Hence the title *Study of a Head*.—I am, yours, &c.

October, 3, 1892.

J. S. Bergheim.

LEYTONSTONE CAMERA CLUB EXHIBITION.

To the EDITOR.

SIR,—In reply to the query of the numerous applicants for entry forms for our forthcoming exhibition on November 10, 11, and 12 next, as to who are the judges, will you kindly announce that A. Horsley Hinton, Esq., Rev. F. C. Lambert, and E. J. Wall, Esq., have to officiate consented on that occasion.

Intending exhibitors of apparatus, &c., and those wishing space for stalls, are requested to send in their applications as soon as possible. Thanking you in anticipation, and apologising for taking up so much space in your valuable JOURNAL, I am, yours, &c., ALBERT E. BAILEY,

Hon. Secretary Exhibition Committee.

Rose Bank, South-west-road, Leytonstone.

MR. HUBERT AND "UNFORTUNATE."

To the EDITOR.

SIR,—Some time ago Mr. Hubert, I believe, promised to report *re* progress of "Unfortunate" printer. That report has not yet appeared, although I think I am correct in stating that the three months have elapsed.—I am, yours, &c. H. J. WILLIAMS.

2, *Fort-street, Douglas, Isle of Man.*

Exchange Column.

Exchange Safety bicycle for Talmer hand camera and cash, or half-plate camera, &c.—Address, W. E. PEARSE, 16, Thanet-street, London, W.C.

Wanted, quarter-plate, with Eastman carrier and casket of lens, in exchange for complete full-plate outfit, nearly new.—Address, A. E. FOSTER, Thornbury, Bradford.

Will exchange excellent background, interior, for another good interior. Exchange photographs and particulars.—Address, J. HOATON, Photographer, Caroline-street, Cardiff.

Wanted, good cabinet portrait lens, about eight inch focus, by Ross or Dallmeyer, or any good recognised maker, in exchange for first-class cripper tricycle, suitable for lady or gentleman, with luggage carrier and accessories. Cost £21. Also two glass cases of stuffed birds, one perrigren falcon and one bittern; for good interior or plain backgrounds.—Address, B. Pearce, Machynlleth.

Will exchange *Studies in Artistic Printing*, by C. W. Hearn, *A Manual of Photography*, by Robert Hunt, F.R.S., and THE BRITISH JOURNAL OF PHOTOGRAPHY, Nos. 1525 to 1636 (one or two missing), containing the articles "Coloured Photographs" and "The Art of Retouching," by Redmond Barratt, for studio stand, tripod, or accessories.—Address, S. L. LEES, 11, Claremont-terrace, Grove Green road, Leyton.

Answers to Correspondents.

All matters for the latter portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

John Reese Jones, Maidstone.—*Cabinet photo of Rev. Dr. Selgwick.*

David Stickells, Cranbrook, Kent.—*The first passenger train on the Paddock Wood and Cranbrook Railway taken at Hope Mill Station.*

*** Several answers to correspondents are unavoidably held over.

F. C. BEACHAM.—The medium appears to answer.

F. I. C. wishes to know the address of manufacturers of "wire glass."

C. F. TREBLE.—We shall probably not again refer to the matter.

E. YEOMAN.—Your suggestion is an excellent one, and we will adopt it.

R. H. MCBEAN.—Our correspondence columns are open for the ventilation of the subject.

J. J. P. BOWLER.—Sponge the surfaces of the pictures over with beer, and employ orthochromatic plates.

R. FRANKLIN.—Your query in no way relates to matters photographic. Better consult such a work as *Spon's Workshop Receipts.*

EDWIN PETIT.—Obtain Burton's book on *Photographic Processes*, published by Marion & Co., Soho-square. In this column space is too limited to give working details of processes.

ALEXANDER BROTHERS.—There is an article on "Solar Enlargements" in the ALMANAC for 1870. The volume is out of print, but may no doubt be obtained by advertising for it.

R. PRITCHARD.—Morrell, of Great St. Andrew-street, W.C., and several other firms whose addresses you will find in our advertisement pages, will supply you with mouldings for frames.

OXON.—Paraffin oil casks are the cheapest receptacles that can be used for the collection of silver residues. The smell of the oil will be of no moment. Hence your fears are unfounded.

G. S. D.—Mr. Valentine Blanchard's address is the Rectory Farm, Harston, near Cambridge.

J. B.—We cannot undertake to recommend one maker's lenses in preference to those of another.

G. B. RODGER.—1. Messrs. Tunny, of Edinburgh, would probably produce the enamels of the desired tone for you. 2. The carbon process is that generally employed for "red prints."

PUSH.—Any of the coal-tar colours that are soluble in alcohol, and the majority of them are, will do to add to matt varnish to give it a tint. Aurine, for example, is very soluble in spirit, and would answer the purpose.

R. C. E.—It is quite possible that you may obtain some sharp hand-camera pictures of the steeplechase next month; but rapid plates must be employed, and also a lens that will define with a large aperture, say *f*-6. All, however, will depend upon the weather at the time. By all means be ready to make the attempt.

S. GEDGE.—Several attempts have been made to induce the different railway companies to treat photographers, as regards reduced fares, on the same terms as they do members of angling societies, but without avail. The West London Society quite recently took the matter in hand with vigour, but the companies proved obdurate.

A READER (Kilburn).—Any manual of photography will give the desired information. An elaborate article on the subject will be found in the ALMANAC for 1888, and plenty of articles in the other ALMANACS and back numbers of the JOURNAL. Space in this column is too valuable to permit of repeating what is to be found in recent issues.

A. COLLYER.—Any of the published formulæ for toning baths will yield rich tones, of a more or less purple shade, with good paper—that is, if the negatives are of the right character. The tones of a print, when rich purple ones are in question, as we have frequently explained before, are dependent upon the negative. The toning-bath formula is quite a secondary matter.

N. A. W.—Plate glass must be used for collotype work, but not necessarily so thick as that mentioned. For the smallest sizes three-eighths of an inch will be ample. For the largest sizes half an inch to five-eighths is quite sufficient. Anything thicker than that very materially increases the cost of the glass, and is not really necessary, unless the bed of the press is not perfectly true.

R. CORDWELL.—Eosine, erythrosine, cyanine, and other substances recommended for orthochromatising plates, can be obtained from most, if not all, photographic chemists. They are also, we believe, supplied by many dealers in photographic goods, or they will procure them to order. The materials, with the exception of the last-mentioned, are not at all expensive.

CHAS. E. LAST says: "Can you tell me the best means of obtaining the following information? I want to find the address of a good photographer at Pau, and also at Peune or Villeneuve-sur-Lot, France, whom I could apply to for photographs of one or two places in the neighbourhood. I thought you perhaps might know the means of finding any addresses in the profession, or could tell me how to find them."

B. BENSON, JUN.—If the gentleman sat at your solicitation, and accepted a dozen prints for doing so, you were perfectly justified in making the portrait copyright. The gentleman, it seems to us, has no right to give another photographer permission to copy the picture, as you hold the copyright in it. There is nothing, however, to prevent him from giving the man a sitting in the same way as he did to you.

CELT.—If the bath be made according to the formula given, it will certainly yield good tones with gelatino-chloride paper. But the stability of the print is somewhat doubtful, as the colour is produced by sulphur toning. Sulphur toning, as some of the oldest prints prove, does not of necessity produce fugitive results, although, while other methods which promise greater stability are available, its use should be eschewed.

ORLANDO.—There is always a certain amount of risk in printing from gelatine negatives before they are varnished; but if the hyposulphite is thoroughly removed, and the film perfectly dry, and the paper quite dry also, the risk is reduced to a minimum. As a matter of fact, a very large proportion of the negatives taken, particularly by amateurs, are printed from before they are varnished, if, indeed, they get varnished at all.

C. E. S.—Unless the seller is a duly qualified pharmaceutical chemist, it is illegal for him to supply cyanide of potassium or bichloride of mercury for photographic or any other purpose. We are quite aware that some dealers in photographic materials do sell them, but in doing so they contravene the Poisons Act, thereby rendering themselves liable to a penalty. Hence you will see that you are not misinformed, and the risk you incur.

HALLAM.—It is quite possible that some London houses are lax in the way in which they execute orders. But their customers have a very simple remedy in their hands, namely, to transfer their orders elsewhere. What good would arise from the publication of your letter? It would be of little, if any, interest to the readers, and would not remedy what you term a "growing evil." *Anonymous* letters on such subjects are not reputable.

KALIUM.—The electric light in the studio is equally as applicable to copying as to portraits. As a matter of fact, by far the larger proportion of the negatives for typographic blocks are made by artificial light during the winter months, the electric light being the illuminant employed. If you have the electric light in your town, you will find it more economical to obtain the current from the mains, for whichever purpose you require it, than to instal plant for its generation.

S. B. A.—In this column it is impossible to give the working details of the collodion process. We must refer you to some of the old manuals of photography, as well as to the innumerable detailed articles on the subject which have appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY and its ALMANAC. We may mention, however, that you are under a misapprehension in surmising that, as you are so well versed in the use of dry plates, you have not much to learn for wet. The knowledge gained in the use of the former will avail but little in learning the wet-collodion process.

A. W. J.—1. Each of the formulæ given in the current ALMANAC for orthochromatising plates answers well. Some brands of plates, with them, answer better for some subjects than others. A few experiments with two or three different brands will soon show which will answer the purpose best. The class of subject you propose to deal with is an exceedingly difficult one, and, to ensure success, a few tentative experiments may well be expended.

A. T. says: "I have been trying the ferrous-oxalate developer for plates, as I am told it is used almost exclusively on the Continent. But all my negatives with it have a faint whitewashed or milky appearance when dry. Is this the general appearance of negatives developed with iron, or is it something in my manipulations?"—The opalescence is caused by lime in the water forming oxalate of lime. It can be removed by treating the negatives with very dilute hydrochloric acid. A few drops to the ounce of water will suffice.

PICKWICK.—Some wall-papers form a very good background, but of course the patterns must be very unobtrusive and subdued, or, at least, show as such in the photograph. Plain papers known as "grounds"—that is, paper with the ground upon it before the pattern is printed—if of a suitable, tint and neatly hung, forms an excellent plain background. In this case the paper should be hung horizontally instead of vertically, beginning at the upper part first. Any paperhanger will do the work in this way if so instructed.

C. MATHESONS says, "I have several old silver spoons that are worn out; can I convert them into nitrate of silver?"—Nitrate of silver is made by dissolving the metal in diluted nitric acid, and then crystallising. But, as standard silver is alloyed with copper, nitrate of copper is also formed, so that from the spoons a mixture of nitrate of silver and nitrate of copper would be obtained. The copper can be got rid of; but, in the case of one having no chemical knowledge or appliances, the best way will be to sell the old metal to a refiner, and purchase nitrate of silver, or take it in exchange for the metal.

J. H. MARTIN writes as follows: "I have in my possession a negative of a part of the town taken twenty-five years ago, and my father (now deceased) lent it to a friend conditionally that he kept it to himself and made no show of it. He has an enlargement of it in his shop, and I hear he has also made some lantern plates from it. If I have the negative registered, can I stop him from exhibiting the enlargement? He promised at the time that he would not exhibit it, and it is my desire to prevent him doing so, as I, having the original, think I am justified in doing."—If the negative was lent under the conditions stated, it is a mean action of the borrower to make use of it contrary to them. Under the circumstances, we fear you have no legal remedy.

PERPLEXED writes: "I enclose a print, round the edge of the vignette of which you will discern some small white spots, that have come out on it after mounting. It was toned in a tungstate of soda bath, fixed in a one-to-five solution of hypo for fifteen minutes, put through a salt solution to prevent blistering, washed sixteen hours in running water, and mounted with Glenfield starch, at which time they did not show on the print, but in a day or two afterwards two or three prints out of each batch were similarly spotted, and I have not been able as yet to trace any on prints of the same batch which were unmounted. I shall be very pleased if you will kindly give me your idea as to what you think would cause such spots."—As only a few prints out of each batch became spotty, the cause would seem to be something in the manipulation. If all became equally effected, then the mounts or mountant might be suspected. Of course it would be impossible to hazard an opinion as to what, in the working, is the origin of the spots, on the data given.

"WATER" says: "We should esteem it a favour if you could let us know how to get out of a muddle we are in with washing our prints. We will explain matters. This last two days the water has become very milky, although after standing a short time it clears and settles on the edges of the washer in minute air-bells, the milkiness really being due to the air-bells. We are using a Wood's 12×10 washer, and as soon as the prints start washing the air-bells settle all over the faces of the prints like scum, and they will not go round in the washer in the usual way, but stop where the water comes in, the consequence being that they blister frightfully, and, of course, get very much injured. Could you tell us of anything that would do away with the air-bells in the water, as that is really the cause of the muddle, the water being so full of air-bells that the prints are not heavy enough to sink in the water? We may add that we are supplied direct from the main."—Water supplied at high pressure is often charged with air, and this is clearly the case in the present instance. The remedy is not to use the water direct from the main, but to receive it in a receptacle where it can rest for a few hours, so that the air can have time to escape. Have a cistern put up to receive the water, and draw from that.

F. H. asks: "Can you kindly inform me the reason of my toning bath turning brown after it has been used about three times? There is also a difficulty in getting it to tone after it turns brown, as if there were no more gold remaining. The bath I use is chloride of gold, thirty grains; acetate of soda, one ounce; and four drops of saturated solution of carbonate of soda; water, sixty ounces. I never had any trouble with the bath until I used ready-sensitised paper. Will you kindly give me a formula for blue tones on albumenised paper?"—The reason why the toning solution turned brown is that something has been introduced into it that has caused a reduction of the gold. When the gold is reduced, of course there is none left to tone with. Some papers seem to introduce foreign matters into the toning bath; when this is the case, only sufficient solution should be prepared at a time to tone the number of prints to be dealt with. We do not approve of the system of making a strong solution as in the formula quoted, and using it direct for toning time after time. A better way is to make up the solution with, say, half the quantity of water, and keep it as a stock solution; then, when any is required for use, take sufficient of it to tone the prints in hand, allowing, say, a grain of gold to a sheet of paper, and dilute with water. After use, this may be kept, and more of the stock solution added when more prints have to be toned. A formula for blue tones is given in the ALMANAC.

LENS.—The lens being a doublet of somewhat ancient construction, and not by a first-class maker, we question much if any advantage will be gained by enlarging the opening in the fixed diaphragm, unless you will be satisfied with impaired definition.

PHOTOGRAPHIC CLUB.—October 12, Members' Open Night. 19, Demonstration with the Platinotype Company's Magnesium Lamp.

LIVERPOOL CAMERA CLUB.—October 26, *Ilford Printing-out Paper, and the Methods in Use to Obtain the Best Results*, by Mr. W. A. Brown.

THE Salon Club, which has now been in existence twenty-six years, will commence its monthly dinners for the season at the Café Royal, Regent-street, on Monday next, October 10.

IN the *English Illustrated Magazine* for October, there is an illustrated article on "A Summer Among the Dovecots." Mr. Alfred Watkins, of Hereford, is the author, and the illustrations are from his photographs.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—October 13, *Practical Demonstration of Retouching*, Mr. Redmond Barrett. 20, First Lantern Night of the season, and Judgment of Competition Slides. 27, Members' Open Night.

MESSRS. GILMER BROS., the sole representatives of Messrs. Clement & Gilmer, of Paris, have removed from Victoria-buildings, Temple-row, Birmingham, to more spacious premises at Manchester-buildings, Cannon-street, Birmingham.

LEYTONSTONE CAMERA CLUB.—October 15, Lecturette, *Hand Cameras*, by Mr. D. G. Riddick. 22, Lecturette. *Stereoscopic Photography with a Single Camera*, by Mr. A. P. Wire. 29, Members' Lantern Evening. To commence at eight o'clock.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—October 17, *A Chat about Eastman Products*, led off by Mr. Baldwin. November 7, testing of competition slides. 21, *The Pleasures of Photography in the Study and the Field*, by Mr. C. Eldridge.

THE following gentlemen have kindly consented to act as Judges at the South London Photographic Society's Exhibition, to be held on November 24–26, 1892, at the Peckham Public Hall, Messrs. F. P. Cembrano, jun., A. Pringle, and L. Warnerke.

MISS CATHERINE WEED BARNES informs us that in future the business of the *American Amateur Photographer* and *Outing* will be conducted under the style of the American Photographic Publishing Company. Dr. J. H. Worman is President, Miss Barnes Vice-President, and Mr. F. C. Beach Secretary.

NORTH SURREY PHOTOGRAPHIC SOCIETY.—The following are the officers of this Society:—*President:* Mr. J. Morrish.—*Vice-President:* Mr. Lewis Wolff.—*Committee:* Messrs. F. Chambers, J. G. Dalzell, T. J. Bright, J. Larcombe, H. Senier, F. Fitzpane.—*Hon. Secretary* and *Treasurer:* Mr. R. W. Wilson, 42, Norwood-road, S.E. Meetings first and third Tuesdays in each month at 369, Norwood-road, S.E.

THE Hackney Photographic Society will hold its Annual Exhibition and Competition at the Morley Hall, Triangle, Hackney, N.E., Tuesday, Wednesday, and Thursday, November 15, 16, and 17, 1892. Apparatus by all the leading photographic firms will be shown, together with novelties and improvements, and demonstrations of the working of the various processes. The judges in the competition will be Captain W. de W. Abney, C.B., R.E., F.R.S., F.C.S., &c., Colonel J. Gale, and Mr. Ralph W. Robinson. Captain Abney will present the prizes.

"THE Life and Work of Professor Hubert Herkomer, R.A.," will this year form the subject of the *Art Annual* or Christmas Number of the *Art Journal*. The artist, in addition to placing a large quantity of material and illustrations at the publishers' disposal, has himself contributed a full-page original etching. In addition to a photogravure plate of *The Last Muster*, there will be illustrations of the artist's principal pictures, *Pressing to the West*, *Chapel of the Charterhouse*, *Found*, *Our Village*, *On Strike*, &c., also of his well-known portraits of *Miss Grant*, *The Lady in Black* (*Entranced*), *Archibald Forbes*, *Dean Liddell*, &c., together with views of the new house and specimens of the architecture and decoration, which are all being carried out from Professor Herkomer's own plans and designs, and executed under his personal superintendence.

FORTHCOMING EXHIBITIONS.

October 11-13.....	Bedford and District Amateur Photographic Society.
,, 17	Camera Club.
November 10-12...	*Leytonstone Camera Club.
,, 15-17...	*Hackney Photographic Society.
(Date not fixed)	Exeter Amateur Photographic Society.
November 17-19...	Brixton and Clapham Camera Club.
	North Middlesex Photographic Society.
,, 24-26...	South London Photographic Society.

* Signifies that there are open classes.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1693. Vol. XXXIX.—OCTOBER 14, 1892.

ARCHITECTURAL DISTORTION BY THE HAND CAMERA.

When, a few days ago, a friend called and submitted a large collection of views, mostly taken in Antwerp and Bruges with a hand camera, he said that he desired to produce lantern slides from them, but encountered a difficulty, arising from the fact of the camera not always having been held quite level. This, as every intelligent photographer is now well aware, produces a want of parallelism in the lines of a building, a topic we have treated on more than one occasion.

To see the perpendicular lines of a building converge is even more offensive than when such lines are curved. But there are circumstances under which, as in the instance cited above, it is not easy to avoid such a fault. Who that has in front of him a tall edifice, which he is desirous of obtaining, but must wish to have it complete from top of spire to basement? But, unfortunately, hand cameras—so few of which possess either rising fronts or swing backs—do not lend themselves to obtaining a building in this way; hence the pointing of them upwards becomes a species of necessity, notwithstanding the certainty of convergence of the perpendiculars.

In one of our Almanacs of a few years ago the method of obviating this was pointed out. It is not by any means difficult to produce a quite undistorted negative from an original that is replete with distortion of every kind; but it is a still easier procedure to print correct lantern slides from such a negative, and, as the lantern season is now on, a few hints relative to this will probably prove useful to many.

We must presuppose that, when lantern transparencies are to be produced from distorted negatives, it is indispensable that they be made by a camera. Superposition will not do in this case, as it only serves to perpetuate the defect. It is also of importance that the lens to be employed for this purpose be one of short focus. One that we have employed in this way has a solar focus of three and a half inches, which represents an effective working focus of seven inches when copying a thing the size of the original.

A very pronounced degree of converging distortion, such as we found in a negative of the Antwerp Cathedral of Notre Dame, cannot so easily be cured when a lens of long focus is employed, because with a swing back in the copying camera the amount of the swing is frequently insufficient. It is now only necessary that, when the negative is erected at one end or in front of the camera, the back has to be swung to such an extent as to cause the convergent lines of the original to appear quite parallel.

To prevent any blurriness which would arise from the top plane of the plate being proportionately farther away from the negative than the bottom, a very small stop must be employed during the exposure.

When once the camera is adjusted for one of a series of quarter-plates, or whatever other size those of the hand camera may be, there is no occasion to disturb such adjustment until the whole series has been printed. All that is needed is to look upon the focussing screen after each operation to make sure that just the right amount of tilting the screen has been given, for some negatives may be very much less distorted than others.

PRINTS *VERSUS* PROCESSES.

The present Exhibition at Pall Mall is pregnant with examples of the varieties of effect that may be produced by the selection of different printing processes. The prints of to-day, as there displayed, for variety of effect and artistic feeling, offer a conspicuous contrast to those of only a decade ago. The art side of photography has been the gainer, but who shall say what will be the verdict ten or twenty years hence? If the Council of the Society had the power of compulsory purchase of all pictures gaining medals, especially with new modes of working, and would act upon it regularly, hanging or preserving the prints in a suitable way for ascertaining the extent of their power to withstand the effects of time under ordinary conditions of storage, an exceedingly valuable collection of data for forming a judgment on the merits of the varieties of processes, as they become popular or otherwise, would be always available. As things now stand, the question of fugacity never arises with regard to medalling pictures at the Exhibition; and the photographic public generally give no particular heed to it. The researches of Messrs. Davanne and Girard, of more than a quarter of a century ago, dealing with the causes of fading of prints by then-known processes, are still the most complete and scientific elucidation yet published of the chemical changes undergone by a print during the chemical operations it passes through, subsequent to the production of the image in the printing frame. No new lines of investigation have been indicated, and, more important still, the plain lessons to be taught by these able investigators' experiments are frequently ignored, and a manner of working in direct opposition to them is by no means seldom adopted. Not by any means should experiments in novel directions be discountenanced; but, at the least, they should be guided by judgment and directed by knowledge of ascertained facts. Some of the effects to be obtained do not necessarily touch the question of permanency; thus we have prints matt and prints glazed; prints very smooth and prints very rough; prints on white, prints on coloured paper, none of which varieties of appearance have any necessary connexion

with the permanency or otherwise of a print. Nevertheless, some of these particular effects are bounded by the lines of processes where a very important question of permanency or fugacity arises.

We are led to pen these remarks by a suggestion recently made to us by Miss Weed Barnes in the course of a conversation upon exhibitions. It was to the effect that a very desirable feature would be a collection of a variety of prints by as many different processes as possible, from one and the same negative. Both photographers and the public generally might be taught an interesting lesson from such a set of photographs. We are aware that before now prints executed in different styles from a single plate have been exhibited; but the suggestion under consideration is that the set should be a representative one, including not merely two or three pleasing varieties, but as large a number as possible. Mechanical processes might be excluded, seeing that few photographers possess a knowledge and working skill with "process work" as well as ordinary chemical methods; but, apart from these, such a collection should be exhaustive, and include silver, carbon, iron, uranium, &c., developed prints and so on, and each in all its manifold varieties of colour, texture, and surface. We were quite in sympathy with the idea, but felt strongly that it should be enlarged upon. Thus all practical workers know that a certain class of negative is far better adapted than another for producing the best results of a particular process; one style of printing will suit almost any negative, another will be best exemplified when the prints are brought to a special hue or "tone." Some modes of printing can be best carried out from a weak and others from a strong negative; there are few in which the character of a negative is matter of indifference. The suggestion, elaborated as above, therefore would assume the form of a series of pictures by as many known processes as possible from each negative of a set of at least three negatives —dense, thin, average as to depth.

Our opinion is that, if the Photographic Society of Great Britain would offer as a subject for a medal a class embracing the best set of prints from three or more negatives of different depths of density, the prints to be done by as many different processes as possible—the size might be kept down to avoid burdening the wall-space—there would be many competitors, and the result, as encouraging more especially the scientific side of photography, would be equally interesting and popular, and to the careful observer in the highest degree instructive.

In close relation to this subject, and since penning the foregoing remarks, we understand that the Photographic Society has decided to purchase a selection of the photographs shown at its various Exhibitions, commencing with that now open. Not only should this collection form, in future years, a clear reference guide to technical and artistic progress in photography, but it should constitute an instructive, and, at the same time, officially provided, object-lesson in the comparative stability of the different methods of printing employed from time to time.

RESTORING FADED ALBUMEN PRINTS.*

Before resorting to further treatment of the print, it will be well to prepare it for the uniform absorption of the solutions, and also to remove any mechanical dirt that may have become attached to its surface in the course of time. For the latter purpose the best plan will be to sponge it gently with warm soap and water, and, if the operation be performed before removing the print from its mount, there will be less danger of injuring the surface or laying the foundation for future irregularity of action. A copious washing should, of course, follow the soap treatment.

The process of unmounting is frequently a tedious one, especially with prints of any considerable age, and more particularly still if the mountant has been of a gelatinous character. The tendency on the part of the print to adhere tenaciously in some parts, while others leave the mount with perfect ease, is very remarkable, and seems to point to some chemical change in the mountant in the direction of insolubility. In all cases, then, we recommend a preliminary soaking of the picture for some hours in cold water before attempting to separate the print from the mount. This will have the effect of softening the latter, which may then be stripped away in layers, leaving only the final one in immediate contact with the photograph, to be removed by a final treatment with *hot* water. But, even if this amount of care be exercised, the separation is still often a matter of some difficulty, and great care has to be exercised to avoid tearing one or other of the surfaces.

Though, of course, damage to the surface layer of the mount is of comparatively little importance, it is better to avoid even that, if possible, for, in addition to the difficulty there is in deciding with certainty which of the surfaces is tearing, any small fragments of the mount that may remain attached to the photograph will require removal by scraping or friction of some sort, which alone presents a chance of damaging the print, so far as its paper support is concerned, and it is in every way desirable that this should remain intact. The only safe course is to allow plenty of time, and to use water at a high—even boiling—temperature. There need be no scruples in doing this on the score of spoiling the tone of the photograph or otherwise injuring it, beyond a slight chance perhaps, with highly albumenised papers, of blistering or separation of the albumen surface; this, however, is a somewhat rare occurrence, and one that will cause little inconvenience if the blisters are not broken.

If the mount should prove still refractory, the print may be soaked for a short time in very dilute hydrochloric acid—about one part to twenty of water—at the ordinary temperature; this treatment we have never found to fail, and, if it exercises any effect beyond the softening of the mountant, it is of a beneficial character rather than otherwise, for, by also softening the size of the print, it tends to promote uniformity in the subsequent action of the solutions, while it may also help to remove any discolouration due simply to deterioration of the paper. On no account should alkaline solutions be employed, on account of their injurious action upon the albumen surface, and even in applying soap, as first recommended, it should be of the best and mildest quality.

Having successfully removed the print from its mount, if such treatment has not been already resorted to, it is desirable to immerse it for a few minutes in very hot water, after which it should be laid albumen side downwards upon a sheet of glass, and the back gently sponged to remove every trace of the old mountant and any minute particles of the mount that may have escaped previous notice. These precautions may be deemed exaggerated, but their neglect may be the means of causing spots, "mealiness," or other irregularities in the subse-

* Concluded from page 627.

quent chemical processes; and, as their adoption adds little to the trouble involved, it is worth while to do the thing properly. The acid bath may be used also if thought proper, either by itself or in conjunction with the sponging, but the free acid in the bleaching solution will perform all that is necessary if the print be otherwise carefully prepared.

We may just add, that the complete success of the restoring process depends rather upon the proper performance of these "minor" operations than upon the chemical reactions that follow, and this is one reason for laying such stress upon them, and upon thorough washing between bleaching, redevelopment, and toning. By thorough washing we do not mean necessarily prolonged soaking, for the intelligent use of a roller squeegee or similar appliance will prove more effective than the most protracted soaking can possibly do.

The bleaching solution which we recommend above all others is one composed of bichromate of potash, common salt, and a mere trace of hydrochloric acid. The latter addition is not absolutely necessary, but it materially hastens the work, and appears to otherwise act beneficially. The precise formula is immaterial, but the following answers well, and may act as a guide:—

Bichromate of potash	1 ounce.
Chloride of sodium	1 ,,
Hydrochloric acid	2 drachms.
Water	30 ounces.

The energy of the solution depends chiefly upon the free acid and salt, and, when its action becomes slow after treating a number of prints, fresh additions of these ingredients will restore it to its former vigour.

The prints to be restored are immersed bodily in this solution, when the image will be seen to rapidly fade or disappear. It is seldom that the most protracted immersion of a gold-toned print will render the image completely invisible owing to the gold that is present in it, and the appearance of the print before treatment must serve as the chief guide as to when it is sufficiently bleached, the stronger and blacker the tone the deeper will be the colour of the image that remains in the bichromate solution, while with some of the faint brown and purple-toned prints there may be scarcely any trace left. The length of immersion is not, however, a matter of very great importance if only all signs of "fading" from sulphuration and all resemblance to an ordinary silver print be lost. So far as we have been able to ascertain, by treatment extending over some hours, the original image is not apparently affected by possible over-action of the bichromate; so it is, perhaps, the best way to give full time.

On removal from the bleaching solution the print will be found to be stained a bright yellow colour by the bichromate, but this is quickly discharged on immersion in water, disappearing from the back of the print, or the paper, first, and more slowly from the albumen film. Alternate immersions in warm water and treatment with a roller squeegee will remove every trace of bichromate in a few minutes, and nothing then remains but to redevelop. We may repeat here what was said in the first part of this article as to the necessity for performing this part of the work in a subdued light, as, if a strong light be permitted to act on the paper while it contains the chromic salt, the latter may be reduced, and so cause permanent discolouration, or, at least, a stain that will necessitate the use of sulphurous acid or similar bleaching agent.

For the restoration of the image there is a choice of variety of developers and methods of treatment, all, however, consisting in the conversion or reduction of the invisible chloride of silver that still forms the image. The selection must be made according to the character or tone required in the final image. If the neutral black, or cool, grey tones of platinum, gelatino-bromide, or printing-out chloride papers be preferred, nothing answers better than the ordinary development of a bromide positive with ferrous oxalate, though, in view of the trouble of removing the last traces of iron from the paper, many will prefer one or other of the various alkaline forms. We have ourselves obtained the best results of this class with amidol, using the standard formula issued by the manufacturer diluted with ten or twelve times its volume of water. If more or less warm tones are required, a much weaker solution is to be used, and the print exposed freely to light first. Under these circumstances, the development is almost identical as regards colour with that of Alpha paper, and the image so obtained may be toned with gold in the usual way, using, for preference, the gold and sulpho-cyanide bath, which, as in the case of gelatino-developed images, seems to answer better than the gold bath ordinarily used with albumen paper.

With very strongly toned prints—that is, those that have been made from dense negatives and toned to a rich black—we have succeeded in reproducing by development alone a great variety of so-called "photographic" tones in brown and purple, the original gold retaining at least a portion of its influence over the final tone; but obviously, in such cases, the development must be of the character to give a warm colour to the silver portion of the image, and we may add, that it is even then not an easy matter to get the desired tone with certainty.

The prints may be finished off in any desired style as regards surface by the different devices of drying and enamelling. Simply dried and mounted, they present the ordinary appearance of albumen prints with the surface slightly reduced by the treatment. Matt effects may be attained by squeegeeing on to ground glass, and any degree of glaze can be imparted by the usual methods of rolling, burnishing, or enamelling. When finished, we have no hesitation in saying that the result is quite equal to the original print, except, perhaps, in the case of those that have a tendency in the direction of weakness or "delicacy" to start with, for these undoubtedly become further impoverished. We have submitted portions of unfaded prints to the treatment, and the result has in some cases been indistinguishable from the untreated portions, while, in many cases, it is possible to actually improve the tone and character of an unsatisfactory image.

This is particularly the case with over-printed and heavy albumen prints, while we may remark, though it does not come strictly within the scope of this article, that, as a means of improving gelatino-bromide or chloride prints that have been spoilt in development, the process is of the greatest value, as these, from the greater quantity of silver they contain, afford far greater scope for the manipulator than albumen prints do. Thus the delicate grey and flat image may be redeveloped up to vigorous strength, and, *per contra*, a heavy print may be reduced and modified in its gradation.

A Photographic Society for Greenwich.—On Wednesday next, October 19, a meeting, under the presidency of Mr. E. W. Maunder, F.R.A.S., will be held at the Lecture Hall, Royal-hill, Greenwich, to consider the advisability of forming a photographic society for Greenwich. We understand that Mr. Haddon and several gentlemen connected with the Royal Observatory will support the

society if it is formed, which, looking at the admirable opening it has in such a scientifically inclined neighbourhood, we have no doubt will be the case.

Ruby Lamps at the Custom House.—By a new order of the Customs Board the officers are in future to be provided with electric search lamps of a special pattern when "rummaging" for contraband goods on board tank and other vessels carrying petroleum or explosives. The object of this is to avoid the possibility of an explosion while engaged in the work. The order also directs that ruby-coloured lights for the examination of imported cases of "photographic negatives" in a dark chamber are to be supplied. By "photographic negatives" we may surmise that undeveloped plates are meant. One would have thought that the Custom authorities would nowadays have sufficient knowledge of photography to know the difference between a negative and a sensitive plate. Be that as it may, it is to be hoped that some one with a better knowledge of the subject than the Board appear to have will be deputed to see that the ruby glass is of the proper non-actinic character, and that the dark chamber does not admit light.

Carbon Printing Abroad.—Last week reference was made to the fact that, in the earliest days of carbon printing, the exposed tissue was cemented to indiarubbered paper for development, and was afterwards transferred to its final support by the aid of benzol. Although this system has long since been superseded in this country by the use of the commercial temporary support, or, where a large number of copies are required for publication purposes, by making reversed negatives, and printing by single transfer, the old plan is still largely followed on the Continent. Some of the largest publishing houses there of the reproductions of works of fine art still adhere to the old method with indiarubber, notwithstanding the additional trouble and expense incurred. It is difficult to see why this should be the case, seeing that the same end can be obtained by so much simpler and less costly means. Those who still use the original system, we are told, aver that by it they can obtain better results than by any other. It must be admitted that most of the reproductions in carbon of paintings in the foreign galleries are very fine, but are they any better than those produced here by less complicated means—supposing, of course, that the negatives are equal in quality?

Photography as a Witness.—It has more than once been suggested in these columns that in the case of accidents a photograph of the surroundings, if taken immediately after the occurrence, would often serve to show the cause better than any other kind of evidence. The value and practicability of this was well exemplified at an inquest recently held. A servant while cleaning a window fell. No one saw the accident; but her employer, who happened to be an amateur photographer, before anything was disturbed, took a photograph of the window. This photograph showed the position of the sashes, the washleather, dusters, &c., on the sill, and satisfied the coroner that the girl was sitting outside at the time she fell, and was not leaning out from the inside. If the services of the local photographer were invoked by the police in the case of railway and other accidents or catastrophes, the photograph would generally prove the most reliable evidence. It is difficult for the most conscientious witness, some time afterwards, to describe the precise conditions existing at a time of intense excitement and consternation. The time will, no doubt, come when a photographer will be officially attached to every division of police. The subject should receive the consideration of the Home Office without delay.

The New Patent Taxes.—The new regulations with regard to patent fees came into operation on the 1st of this month, and they will prove a convenience to many holders of photographic patents. The advantages of not a few inventions are not fully recognised, or their value fully established, before the inventor has had at the end of the fourth year to pay a 10*l.* renewal fee or to lose his patent. These renewal fees, varying from 10*l.* to 20*l.*, unless a lump sum, in two instalments of 50*l.* or 100*l.*, was paid down, had to be paid; so that the cost of a patent for the full term of fourteen years was 154*l.* By the new regulation made under the late Government, the renewal fees are commencing at the end of the fourth year—5*l.*, increasing 1*l.* annually till the fourteenth year. Thus, instead of a patent costing, for Government fees, 154*l.*, it will now only cost 99*l.*, with the further advantage of smaller payments at the earlier periods. The costs of patents are being slowly reduced in this country, yet the revenue of the Patent Office is increasing. Prior to 1852 a patent for the United Kingdom cost about 400*l.* One had to be taken for England and Wales (150*l.*), one for Scotland (150*l.*), and one for Ireland (85*l.*). Afterwards the law was altered, and one patent sufficed for the whole of the United Kingdom, and the cost for the full term then came to 175*l.* In 1884, the fees were again reduced, and the opportunity afforded of paying them by yearly instalments, as just referred to, until they amounted to a total of 154*l.* Now they only amount to 99*l.* Considerable as is this reduction, the cost of an English patent is much greater than for most other countries, Germany excepted. The cost of an American patent, for example, for seventeen years is equivalent to only about 8*l.* 10*s.* However, English photographic patentees will be thankful even for small mercies.

THE CAMERA CLUB.

The Camera Club Invitation Exhibition will be formally opened by the President (Captain Abney) on the evening of Monday next, October 17, and it will remain open to Thursday, December 8. The Hanging Committee were Colonel Gale, Mr. H. P. Robinson, and Mr. George Davison, and the preparation of the catalogue has been entrusted to Mr. Maskell. During the autumn the premises of the Club have been redecorated.

Captain Abney, Messrs. Pringle and Burchett, Commander Gladstone, Rev. F. C. Lambert, and Messrs. W. Jerome Harrison and H. E. Armstrong, F.R.S., are to read papers in the course of the ensuing months, and a retouching class, under Mr. Redmond Barrett, is being organized.

We gather from the Club *Journal* that the entrance fee will be raised from one to five guineas on and after January 1, 1893.

JOTTINGS.

It is with deep sorrow that I find myself compelled to confirm the rumour of the death of Her Most Gracious Majesty Queen Anne. Consols remain steady. A second historical event of recent occurrence, and of perhaps hardly less moment than the melancholy demise of that sovereign, and of which an inscrutable Fate has ordained that I should be the means of communication to your many readers is that, after a sanguinary and protracted struggle, in which there was enormous loss in killed and wounded on both sides, the fair land of Holland has at length fallen into the hands of the Dutch. The peace of Europe is therefore assured. Item of historical information No. 3 on my list is that the Exhibition of the Photographic Society of Great Britain is as successful as its best friends could wish. All's well that ends well; but I do not hesitate to say that the powerful support which this Journal has given to the old Society during its recent crises has had not a little to do with assuring the undoubted *éclat* with which the present Exhibition has gone off. However, long life to you, "aged P.," as Mr. Wemwick would say.

In a bright and chatty little serio-comic publication emanating from Manchester, and called *Spy*, I find an editorial article with the heading "A Local Photographer and his Lady Clients." This appears upon perusal to be nothing more nor less than a charge of grossly outrageous behaviour on the part of the photographer towards his lady sitters, conduct for which it is also hinted the precious rascal has more than once been soundly thrashed by irate husbands. *Spy* calls the man a "foreign gentleman (?)," and says that he is one of the best known photographers in Manchester, while at the same time a partial threat is given to print his name. For the credit of an honourable profession, I hope that *Spy* will not stop at half-measures.

but, in the interests of photography and the public generally, will do its obvious duty in assisting to drive this man out of the good city of Manchester. Professional photography is, at the best, a calling of such a precarious nature, that it can ill afford to be further disadvantaged by the doings of such a being as he whom *Spy* describes as guilty of conduct which unfits him for any society but that of gaol-birds.

Among recent applications for patents, I observe one for a walking-stick camera stand. I cannot, of course, tell what the particular features of this invention are, but it is obvious that the scope for variety in such an idea is very much restricted; hence, while I hope that the would-be patentee has hit on a really novel and money-making form of camera stand, I cannot help wondering to myself how many years it is since I first handled a walking-stick stand (the name of whose maker or originator I have forgotten), which consisted of a number of ribs with angled surfaces, all fitting closely together, and when not in photographic use being secured at the top with an iron ring, thus forming a serviceable, if somewhat long and ponderous, walking-stick.

I must take exception to some of the chemistry of sulphite of soda as enunciated at a recent meeting of the Hackney Photographic Society. To begin with, it was stated that some sulphite of soda had been exposed to air, did not dissolve in water, and did not "prevent the stain" to the same degree as the fresh substance. I agree with the gentleman who said that the latter effect was due to the oxidation of the sulphite; but, as to the inference that "oxidised sulphite" does not dissolve in water as well as unaltered sulphite, I should like to point out that sulphate of soda, which the oxidised product is supposed to be, instead of being less soluble than the unchanged sulphite, is really just about twice as easily soluble as the last-named body. Again, "a member had developed a lantern plate with pyro and sulphite only," and "it was remarked that sulphite of soda is alkaline." Not necessarily, and not always; otherwise, how is it that pyro may be preserved with a plain solution of sulphite? It would not if it were alkaline. The sulphite I employ for this purpose is neutral, and that is the variety usually sold by the dealers, I fancy. By the way, has the particular variety of sulphite employed with amidol anything to do with the contradictory experiences which some workers with the new developer seem to be having as regards its keeping free from discolouration for a week or two? Possibly, if the sulphite were invariably acidified, the browning of the amidol solution of which complaint is made would not occur.

The correspondent who inquired whether the light from a coal or coke fire would be sufficient to fog either sensitive plates or paper, like so many others "who write to the papers," might have spared himself the trouble of putting such a question had he but reflected a little beforehand. The flame of a coal fire is practically identical in nature with either gas, candle, or oil-lamp flames, and as he could not, of course, be in any doubt as to the effects of these three flames upon sensitive surfaces, it is a little surprising that he should have supposed (as he evidently did) that a flame from burning coal could be ineffective. All the same, a red, flameless fire, either coal or coke, might possibly have no harmful effects in the developing room, since I assume that in that condition it would give off very little actinic light.

There is no gainsaying the enormous popularity which gelatino-chloride printing papers have achieved, especially among amateurs, in a remarkably short space of time; but the process is still open to considerable improvement in one important respect, that is, in securing regularity and uniformity of tone. At present the tones aimed at are not obtained with anything like the certainty of albumen prints. One characteristic of these papers—the blue *nuance* so commonly seen in the half-tones of the prints—is possibly due to some inherent property of the support, the enamel paper for the various commercial gelatino-chloride papers now in use all coming, I am told, from one source.

COSMOS.

THE OBJECT OF PHOTOGRAPHY.

[Photographic Club.]

HAVING been asked to open the discussion to-night, the above subject has been selected as being important, and as permitting considerable difference of opinion. Let me indicate at once the broad, liberal lines on which it seems to me the discussion should be pursued. As long as human beings are not created free and equal, although a certain well-known document says so, they will differ materially in their objects and their pursuit of them. Especially is this true of mental processes, among which, I claim, photography holds no mean place. The object which each worker has in view may, and often does, differ widely from that which he should pursue in order to obtain the greatest possible benefit, and in thus striking the keynote of my paper I hope to point out in some degree the ideal all camerists should keep in sight. We all know the great moral axiom that we best help ourselves by helping others; indeed, it cannot be otherwise, and this help can be given in many ways, only seen by those whose minds are trained to receptivity of all progressive movements. The human mind is an organ, a function, an intangible, incomprehensible force—what you will; but it is great or small, not only according to the impulse behind it, but the use we make of it. We may look at photography through a narrow or wide-angle lens, through the telescope or ordinary view; there is plenty of choice, all depends on the will of the individual worker. Those who are able to learn by everything teachable in the realms of mind and matter will find that in photography these two forces join hands with greater or less energy according to the object of each worker. Those will gain the most whose ideal is the highest, and, as in union there is strength, so photographic workers accomplish most when organized into societies, provided the standard is held high over men's heads and never lowered from fear of criticism, for any purely personal or selfish motive. What if any individual worker should come more prominently than another into the brilliant electric light of public opinion or approbation. Is that a reason for discouragement or lowering one's own flag? Rather should it be an impetus forward on the principle of the fairy in one of Jean Ingelow's stories. "Don't you know," she said, "that in Fairyland what you can do you may do?" The trouble is, we carry on the fight somewhat on the free-lance principle, and "each one for himself" does not advance the general standard of progress. If individual preference be on the high plane of real altruism, well and good; but, usually, the ordinary human being is more exercised in raising his own special average than the general one of humanity.

"WHAT CAN PHOTOGRAPHY DO TO ELEVATE THE GENERAL AVERAGE?"

Let us consider then what photography can do to elevate this general average. If nothing, it is worthless, but it can do much and it is worthy of thoughtful consideration.

The adage that "beauty is its own excuse for being" does not entirely cover photography. The latter adds to the cultivation of the beautiful, that of the useful. Thousands of feet below the earth's surface, as regards land and sea, has the keen eye of the lens revealed to us once hidden mysteries, and beyond the systems of worlds heretofore unknown has it opened limitless possibilities. What other art or science can claim so much? In the astronomical equipment of Harvard University, near Boston, is being set up the largest photographic lens ever made, to be electrically controlled in correspondence to the motion of the earth. The lens has a twenty-four inch aperture, and will be used on a fourteen by seventeen plate. The time is fast approaching when photography will be utilised in all the countless ramifications of human knowledge, and there is no use in artists or scientists denying what will soon be an undeniable fact. Even on the lowest plane of merely personal help to each individual worker, photography is a pursuit embodying in itself broad scope for cultivating the powers of the keenest brain. Much more is this increased when we take into consideration our fellow-workers. Every thought which finds effect in word or act is a stone dropped into the stream of human life whose widening circles touch and influence countless others.

THE OBJECT OF THE INDIVIDUAL WORKER.

Speaking of the individual worker, what is and what should be his object in this work? We know they are not always the same thing. He begins, we will say, because it is suggested to him as an amusement, and many never get any further. They can be left out of the question; but to those who once begin to make a study of the work and find it broaden into one field after another, filling one's utmost limit of mental effort, the interest grows more absorbing as they realise that however great may be their progress, they will never know all there is to be known. The object which at first is pleasure only in the sense of recreation, becomes then something far nobler as a

powerful factor in training, what we speak of so often, and comprehend so incompletely, the human intellect.

If we accept the object of photography as being a mental education, how can it best benefit us? In every study those gain most who come equipped for work by natural or acquired gifts. Perhaps no one faculty in photography is more quickly called into exercise, or more rapidly improves, than that of observation. As this grows keener, the eyes stimulate the brain to act, and in landscape work alone, a fuller, richer appreciation is daily given us of the world of nature. The shortest journey shows us what we might otherwise pass by unheeding, and extended travel sends us home benefited by a wealth of experiences which many of our fellow-travellers lose. We do not need to go on land and sea for such; often near our own doors we learn to see a constantly varying panorama of change. I do not believe that in any more efficient way can we be helped than by aiding this very faculty of observation, especially in the young, when it can be made a fixed habit.

Portraiture and its Objects.

Passing from the world of nature to that of man, we find that, although we are usually gifted with the same physical organs and general appearance, that such are capable of infinite variety when looked at from different standpoints. In portraiture, the object should be to truthfully and kindly represent the sitter's best aspect. We have in this to struggle against preconceived prejudices, as people always think they know for themselves what the old woman called her "congregation side," and it is well occasionally to see ourselves with others' eyes. Once in a portrait gallery I heard a lady say, looking at her proof, "I don't like it at all, but it looks just like me." Another time, the photographer said to me, "There's Mr. A. has been here four times this week to sit, and yet is not satisfied." Do we all know our best side? Every portrait photographer who properly knows his business, understands that the first grand requisite of success is to make the sitter feel at ease under far different circumstances from his usual ones. It would be well if this was more carefully considered and made a more striking feature in our studios, but it draws heavily on one's nerve force, and necessitates more of a strain than most operators are willing to endure, unless really in love with their work, which the majority are not. I have had occasion to see a good deal of the inside of a professional studio, and a day's observation of the different sitters gives an entertaining study of human nature. I have often thought it would pay to have a regular adviser or art director in the studio to advise sitters, men and women, for one is no wiser than the other, what to wear and how to wear it to obtain an effective picture. If the operator attempts this, he too often meets a sharp rebuff. The amateur, if he be willing to use time and patience, has often a great advantage over the professional in respect to this question of being at ease, as his work is done usually amid familiar surroundings. I undertook once to photograph an old artist friend, who would not assume any but the stiffest possible pose of the shoulders, until I placed a palette and brushes in his hand, when his whole attitude became at once perfectly easy, because natural. Figure studies, to one who has a taste for them, are the most fascinating and, at the same time, most trying and difficult branch of photography. There is always something to learn in it, and its difficulty is, to me, its greatest charm. What is easy presents no attractions.

The Uses of Photographic Societies.

Every worker is more or less influenced by others, therefore he best utilises his own efforts, and in his turn exerts influence, by joining, as before suggested, a photographic society. The ideal one has yet to be invented or evolved as the tribes of men increase in not merely technical knowledge, but common sense. As at present constituted, they form, in the main, excellent schools as regards practice for those workers already somewhat proficient, but should do more for the beginner than is the case. As managed here and in America, they vary greatly, and each might gain by adopting some of the others' methods. I differ from my compatriot, Dr. Mitchell, in his advocacy of the club system, believing in the work as a mental education, not as a mental recreation. One point generally lost sight of in such organizations, as soon as they become prosperous, is the great law of majorities—the greatest good of the greatest number. Few human beings are capable of self-abnegation under such circumstances, and when they are, it is often to meet criticism, if not opposition, on the part of those less disinterested than themselves. The true worker should, however, like the Alpine climber on the glacier, be so busy in cutting steps for his feet, that he cannot watch the progress of others, but must attend to his own. When comparative success is gained, then comes the danger common to success, believing the summit has been reached, than which there is no more fatal delusion. It is possible, in tracing out the various by-paths of photography, to make the pursuit in large measure a liberal education, and the widest culture can be used advantageously. I believe in a sound technical training in optics, chemistry, and mechanics, an elementary, if no more, art training, and a wide reading of the best general literature. Here is where so many photographers — more professionals, perhaps, than amateurs—fail to realise the importance of cultivated intelligence in what claims, and rightly so, to be ranked among the fine arts. One should also make a point of keeping in touch with all that is being said and done through the various photographic journals in different countries, not work on blindly in one's own little special pathway.

Photography an Adjunct to Mental Studies.

If the object of photography is to educate, that means liberalise, and for this a thousand ways are opened through literature, science, and art. Decrying the increase of illustrations by photography as injuring wood-engraving, for instance, is like the rebellion of hand-work as against machinery. The world does move if people will act as did some Indians once on the American prairies who attempted to stop a train by holding a long leather lariat across the track. The Indians suffered, not the train. Photography is a most important adjunct in nearly all mental studies, and will become more so as its facilities for work increase. Let each one, therefore, follow out his or her own salvation, grateful for criticism or praise, whichever best aids in keeping high the standard already indicated. Lenses, cameras, instruments of all kinds are only means to an end, discussions upon them and upon methods of work are only valuable as they conduce to the further elevation of photography itself.

I feel strongly on this subject, believing firmly that photography can be of such incalculable benefit to all who pursue it with singleness of purpose, or with a desire to help others. In this connexion let me heartily endorse and offer hearty co-operation to the affiliation scheme recently proposed by the Cheltenham Society. It is a move in the right direction, and deserves the endorsement of similar organizations, wherever located. While not criticising those who look at the object of photography from a different standpoint than my own, I merely place myself on record as regarding photography in the light of a vital, educational force; a responsibility, and not a plaything; a power which can be used in so many ways when seriously considered that I cannot but feel it a privilege to be numbered among its adherents. Time and conscience prevent my wearying you with a longer paper, and yet I feel the subject has been very inadequately treated, my only consolation being that, in presenting it to you, I am enabled to emphasise my strong interest in the work to which my time and energies are devoted.

Catharine Weed Barnes.

AMIDOL.

This new developer has come to stay. Such is, I venture to say, the opinion of all who have tried it, or, better still, used it for many negatives, and on various occasions, because the ability to pronounce upon the merits of an article simply by trying it, instead of using it, is given to few of us.

The writer has now, for several weeks, used amidol, and has developed over fifty half-plates in the same solution, but additions of amidol, sulphite of soda, and bromide have been made. It will now be explained how and why these additions were made, and it will also show how plastic the material is in the photographer's hands.

Upon writing Messrs. Fuerst Brothers at the earliest stage of all, the writer was informed they could not supply less than twenty-five one-ounce bottles of amidol. (It may be mentioned here that they will now either supply one ounce, or else give away a sample.) Well, after a good hunt round town, three-quarters of an ounce were obtained from a photographic dealer, in a bottle without any label or instructions, accompanied with the remark, "I don't think we shall keep it, as there is nothing like good old pyro." Upon further examination at home, the crystals looked very like hydroquinol, or a preparation of hydroquinone. Being anxious to try the material at once, a plate was exposed in the camera, *short*, *normal*, *and full* exposure being given on one half-plate, by the simple dodge of raising the shutter one-third, two-thirds, and full. Some of the amidol in the meantime was dissolving in three ounces of water; within twenty minutes this was dissolved, poured into a developing dish, and the plate placed in the same. Within a few seconds the three exposures became visible, and eventually the one that had received the shortest exposure was the most satisfactory negative, the fully exposed part being flat and greyed all over, and the normally exposed one being in a similar condition

upon looking at it, but by transmitted light it was seen that the fog or greyness in the shadows was very slight, and would not detract from it as a good dense printer. It may be well to say that the words slow, normal, and full, referred to the exposure needful to have produced a negative of good or full dense printing quality by a hydroquinone developer. The lesson learnt was, Give shorter exposures; which, being translated, meant, This is the developer for the winter days now rapidly approaching, and indicated that it was a most suitable developer for children's portraits and groups and other work in which a minimum of exposure had or has to be given. It may be interesting to mention here that (1) the exposures were made in a studio, (2) the lens was a rapid rectilinear, using the largest stop supplied by the maker, *f*-8, and that on that particular day five seconds was the normal exposure. The "short" portions had two and a half seconds, and the "full" portion seven and a half seconds. That is, half the normal exposure in one case, and half as much again as the normal in the other case.

Now to return to the developer. It soon changed colour, so a little sulphite of soda was added, and by the morning it had considerably cleared, and it is now pale sherry colour. The next day another plate was tried, and after fixing it was seen to be covered with a good many spots; upon examining the dish, it was observed that the sides were covered with fine sand-like crystals. Filter the developer immediately flashed through one's brain. This was done, and the next six half-plates developed came up clean, dense, and just right printing density.

The next day a sample bottle arrived, and with it instructions and proportions; as these will be with the amidol my readers may use I will not repeat the formula, beyond saying amidol is a complete developer by itself; but the addition of sulphite of soda supplies the alkali needed if many plates are to be developed in one solution, and also preserves the solution from the action of oxygen. The makers advise the addition of a bromide, if thought necessary, and it is astonishing what a quantity of bromide of potassium can be used without any perceptible slowing taking place, or even any apparent action.

To resume again. Ten ounces of developer was made up according to formula, and it worked neither better nor worse than the old developer made up by rule of thumb, as stated in the commencement, more of each chemical being added in the advised proportions, and the solution filtered each time after using. *This is very important*, as the crystals do not seem to deposit on the bottle, but remain in suspension.

Two experiments made resulted in failure.

To a hydroquinone developer amidol was added, and a plate developed—result, faint image, universal grey deposit, with a few spots. Next was tried starting the development in amidol, and transferring the plate to a hydroquinone developer—result, fair image, thin, but such a plentiful supply of black spots, evidently the crystals above mentioned, precipitated upon the plate, and thus causing greater density.

To those who have used eikonogen and hydroquinone together, or in separate baths as a developer, the reason will be apparent why the last two experiments were made.

In conclusion, amidol in solution should be on the shelves of every worker, even if not used regularly. It will be found most useful on those negatives that have received a short exposure, or those sitters who photograph with extremes of light and shade, as some rugged faces do, and these so often come on bad days, or after the best light has gone.

The solution now measures ten ounces, and although over fifty half-plates have been developed in it its power is still unexhausted. It may be amidol will turn out to be similar to a good acetate soda toning bath. Just add gold each time you tone, and it will, like Tennyson's brook, "go on for ever." ARCHER CLARKE.

TONING PLATINUM PRINTS WITH URANIUM.

[Camera Club Journal.]

I HAVE recently been working with the new cold-bath platinotype paper, and I find, as no doubt others have done, that many prints, although, as far as one could judge on taking them from the printing frame, the details were apparent, yet, on development, turned out to be under-printed. This, in passing, I may remark, is the only drawback I have discovered in the use of the new paper. The tones in prints rightly printed are admirable, and when brush development is used, the normal developer being mixed with an equal quantity of glycerine, the process of development is very much under control.

As platinotype paper is rather expensive, I thought I would try if the under-printed prints could be improved by uranium toning, and I made up the following solutions:—

A.

Uranium nitrate	10 grains.
Glacial acetic acid	1 drachm.
Water	to 5 ounces.

B.

Ferridcyanide of potassium	10 grains.
Glacial acetic acid	1 drachm.
Water	to 5 ounces.

For use, mix equal quantities of A and B. These solutions, unmixed will keep for an indefinite time, but, after mixing, very soon deteriorate.

The prints are developed and fixed in the usual way, and after they have been dried should be inserted, one by one, in the toning solution, and will then, *if all the iron has been properly fixed out*, tone to any colour, from a nice brown to a Bartolozzi red, according to the time they are left in the solution. In order to make sure of the absence of iron from the paper, it is desirable, when it is proposed to tone prints, to give them an extra bath of double-strength hydrochloric acid; the presence of iron is shown in the toning process by blue stains.

The colour in the prints, when obtained, appears to me to be permanent, but, as I have only recently commenced experiments, it is, of course, difficult at present to be certain as to this. It seems to me that this process could be applied to produce sepia prints, and thus avoid having to use the special paper supplied by the Platinotype Company. F. FITZPAYNE.

THE MANIPULATION OF CHLORIDE OF SILVER GELATINE PAPER.

[Birmingham Photographic Society.]

IN laying before you my method of manipulating chloride of silver gelatine paper, I make no pretentions to exhaustiveness or completeness, either as to the various ways in which the paper may be treated or of the various makes obtainable. Besides some that I made myself some years ago, the only brands I have used much are the Ilford, the Eastman, and the Birmingham Photographic Company's "Criterion," most of my prints being on the Ilford and the Birmingham paper. Although the general treatment of them is the same, they all have various characteristics, which require to be known. They differ from each other in the colour they assume in the printing, and they behave differently in the after-operations of toning and fixing. You will see that they are over-printed, certainly not more, if so much, as albumen prints, and in this particular they compare favourably with some of the older gelatine papers, which required such a depth of over-printing as to render it difficult and uncertain to print to a nicety on them. The loss of depth with these papers occurs mostly in the washing before toning, and they lose but little in the fixing. They lose less with the combined toning and fixing than with toning and fixing done separately. Gelatine chloride paper must be kept dry, as it is more susceptible to damp than albumen paper; if not kept dry, it will give patchy and uneven prints. If the printing is done out of doors, it will be advisable to have an indiarubber pad in the frame at the back of the paper, otherwise it is not necessary. After the printing comes the toning, and the formulæ for toning these papers are very numerous.

TONING AND FIXING WITH THE COMBINED BATH.

The toning and fixing operations may be conducted separately, or a combined toning and fixing bath may be used. The simple toning bath varies from the single sulphocyanide of ammonium and chloride of gold one to one of half a dozen chemicals, and some of the combined baths are stupendous mixtures, containing alum and lead salt abominations. Why they are out of place is because they decompose a portion of the hyposulphite of soda, and liberate a portion of the sulphurous acid and sulphur, which is held in combination. These will combine with the silver of the image, and form sulphide of silver, causing what is known as sulphuration, or sulphur toning, and prints so toned are liable to fade and discolour. I have here a series of eight prints toned and fixed in the combined bath. Four of them are on the Eastman paper, and four on the Birmingham Photographic Company's "Criterion" paper. Two of each sort of paper were treated in a bath containing—

Hyposulphite sodium	4 ounces.
Sulphocyanide ammonium	100 grains.
Phosphate sodium	60 "
Chloride gold	2 "
Water	16 ounces.

The other four were treated in a bath in which one hundred grains of borax replaced the phosphate of sodium, and you will see on inspection that there is no perceptible difference in tone.

All combined baths require an unfixed print or some scraps of silvered paper soaking in some hours before use. The one great recommendation of the combined bath is, of course, that it is much less trouble than toning and fixing separately, there is much less swilling and washing. The danger attending its use is that, when it has been in use some time, the fixation of the prints may be imperfect, and, although the gold may be exhausted, it will go on toning. Now, these conditions, imperfect fixation and sulphur toning, are precisely the conditions under which the print may be certain of a short life, and will result in the unmerited condemnation of paper and bath. I know of no reason why, if the bath be used fresh and with sufficiency of gold, the toning and fixing should not be complete and the prints be as permanent as if treated in any other way; but, if the bath is used too much, you get yellow-stained prints with the half-tones, a most unpleasant colour.

I have here some prints made on the Ilford paper more than twelve months ago, and treated in the combined bath. You will see that they are warm in tone, and the combined bath has in my hands given better results in this particular than separate toning. When using the combination bath, the colour is judged from the surface, not by looking through, and the prints dry perceptibly darker.

Toning Pure and Simple.

Coming now to toning pure and simple, the bath I have used mostly is the Ilford formula, viz.:—

Sulphocyanide ammonium	30	grains.
Chloride gold	2½	„
Water	16	„

When a tube of chloride of gold is broken it has to be made up into a solution of definite strength, and will usually be found to be decidedly acid. A small scraping of ordinary chalk, not French chalk, should be shaken up in it to counteract this acidity. The prints require washing in several changes of water before toning, and they should not be left soaking in the first two changes. On immersion in the toning bath the prints change more or less with various papers to a yellow colour. This soon passes away, being succeeded by a purplish brown, and the progress of the operation is judged by holding the print up against the light. At first the print appears of a reddish colour all over. The next stage the lighter half-tones become dark or black, followed by the middle tones, and when the red has almost disappeared from the deep shadows the toning is complete, the surface colour being of a peculiar bluish purple. A washing in two or three changes of water follows, and fixing in hyposulphite of sodium three or four ounces to the pint of water, a small bit of washing soda being dropped in to counteract possible acidity. The prints require a final washing of about two hours under the tap or in a pan of water changed many times. This toning bath, as you will see from these prints, gives dark tones, being what I might perhaps call a warm black. With this bath I have been unable to obtain the lighter or brown tones on any of these papers.

If the print is taken out while there is any considerable portion of red left in it, you have the shadows of a brown colour, but the lighter parts have toned completely to the warm black, and the result is an unevenly toned print, as in two I will pass round. With this bath, therefore, you have to tone completely, and it has the advantage that you can depend upon getting a very fair uniformity of colour in the prints. The bath will keep, and can be used for some time, but I prefer to use it not more than two or three times, adding, of course, more gold as required. It is recommended to use the old bath as part basis for a new one, but I prefer to make up a fresh one, having a weakness for new and clean baths. Most of the toning troubles with this paper will be found to arise from an insufficiency of gold, and we should be generous with the gold, remembering that the more gold the prints will take up the better it will be for their permanence. I have used the borax toning with the Ilford paper, and have obtained pleasing, warm tones with it, as seen from these prints. The proportion is ninety grains borax to sixteen ounces water; gold, two grains, more or less. Gelatine papers require careful handling, as the gelatine, when wet, is very soft and soluble. Advantage is taken of this softness, when wet, to squeegee it, as it is called, on to a surface of glass, or other suitable non-absorbent material. When dry, it is stripped off, and retains the impression, whether glazed or matt, of the surface on which it dried. All mine are, as you see, matt-surfaced, and are done on ground glass, and as there is sometimes a difficulty experienced in separating the print, or some portions of it, from the glass, I have thought it best to go into details.

How to Obtain Matt Surfaces.

In the first place, you must have the right sort of ground glass; the ordinary window description is of no use at all for the purpose, it is altogether too rough and coarse, and the prints will not separate readily, neither will it give the surface required. The sort to employ is such as is used for focussing screens in cameras. The first thing to be done is to make the glass thoroughly clean, and this I do with soap, soda, hot water, and a scrubbing-brush. I do not find acids ammonia, or suchlike, at all necessary. Give the glass a good, scrubbing on both sides, and then wash thoroughly under the tap, rubbing it all over both sides and edges so as not to leave any trace of soap or dirty water. Then dry off with a perfectly clean cloth. This done, it has to be rubbed over with French chalk on a piece of soft rag. Use plenty of the chalk and rub it well all over, but not hard enough to bruise the talc. If the chalk sticks on to any particular part and will not rub off, it is a patch of dirt, and is insufficiently washed. It is not necessary to wash the glass every time it is used; if it is kept clean and not finger-marked on the surface used, it only requires rubbing lightly over with the chalk. Another point, too, worth noting is that after the glass has been stripped from a few times the adhesiveness of the print is very much reduced. The first time of stripping, the hold on to the glass is so great that you feel sure something will happen, but after a few times the print comes away quite easily and altogether. The print may be squeegeed on to the glass direct from the washing water, or it may be dried first. I usually let mine dry, and lay them down on the glass some other convenient time. Taking a dry print, then, it is immersed in clean water till quite limp, which will be in a minute or two, but do not leave it soaking for a length of time. Having then lightly dusted off the French chalk with a clean, dry cloth, we brush over the surface of the print while under water with a camel's-hair brush to remove air-bubbles and any dirt there may be there, and lift out the print by two corners, bringing with it as much water as we can. Then we lay it down on the glass in such a manner as to cause the water to drive out the air from between, and finish with a few light strokes with a roller squeegee. When it is thoroughly dry, but not before, the point of a knife is inserted under a corner, and the print lifted from the glass.

Edwin Underwood.

PHOTOGRAPHIC INDUSTRIES.

Messrs. Newman & Guardia.

For several years past the name of "Newman" has been associated with the invention and production of several excellent shutters, sheaths, hand cameras, &c., which have enjoyed a large measure of popularity. Quite recently a reconstitution of the firm of which Mr. Newman is the accomplished chief has taken place, that gentleman having associated himself with Mr. J. Guardia, who, we believe, is hardly less expert in photo-mechanics than his partner. As is but natural in modern business enterprises, this new arrangement has led to increased activity in the production of the firm's specialities, and it is doubtless safe to prophecy that Messrs. Newman & Guardia will in the future not fail to occupy and maintain a position second to none in prominence in their own especial line of business.

On the occasion of a recent visit to the firm's business premises, we were pleased to note unmistakable signs of activity, something like forty hands, Mr. Guardia told us, being employed. Hand cameras and the firm's new patent changing backs in various stages of preparation met our gaze, and we were particularly interested at observing the excellence and conscientiousness of the work put into the wooden bodies of the cameras—a point, of course, which in the finished article would escape the attention of the purchaser. In the way of hand cameras, indeed, many movements of great combined simplicity and effectiveness were shown us, many of which are adapted to existing cameras of the firm's make, while others are doubtless to appear in future productions. These included a neat and effective self-capping arrangement, small rapid spring doors for disclosing the lens when one is ready to expose, and other convenient devices. The changing back for either films or plates (which are held in sheaths), both in the action of the lifter and in the removal of the plate to be exposed from the back to the front, ready for exposure, is remarkably simple and reliable.

In the production and fitting of the various parts of the firm's shutters, hand cameras, changing backs, &c., a considerable quantity of ingenious machinery is, of course, employed, and all this, we believe, has either been adapted by Mr. Newman himself or laid down under his personal superintendence; that gentleman also exerting a like degree of supervision over the practical part of the business. Altogether, among

modern photographic businesses, Messrs. Newman & Guardia's fills an excellent position with the best anticipations of considerable expansion.

One of the firm's most recent introductions is the "N. & G." aluminium blind shutter, which is fitted with pneumatic regulation release and stopping gear. Besides witnessing the fitting together of the shutters' various parts, Mr. Guardia showed us a collection of the latter, and it was as surprising as it was agreeable to us to note with what accuracy, finish, and delicacy those parts had been made. A further point deserving of notice is that the parts are interchangeable, so that the replacement of any one of them is effected with the utmost ease.

This interchangeability applies to the blind, which is of a specially prepared material; while most of the parts of the shutter are of aluminium, brass only being used to a small extent and that alone where imperative. The lightness of the aluminium inner rollers and other parts is remarkable.

In action, the lever, as shown in the cut, is pulled up, and the index hand set to the exposure required, as marked on the dial at the side, the release being made in the ordinary way. In working, the absence of jar or vibration is very noticeable—this being due, of course, to the air cushion at the bottom of the cylinder. It is claimed that this gives the working parts an immunity from wear and tear, and we should think that practice would well justify such a claim. The shutter may also be used for time exposures, the figures on the dial marking exposures for from one second down to a fiftieth. It may be fitted at the back of the lens, on the hood or front, or between the lenses. Mr. Newman informed us that the system of testing the rapidity of the shutter ensures great accuracy.

Light, well made, neat, simple, and scientifically thought out, the "N. & G." shutter is a veritable photographic luxury and, at the same time, undoubtedly a useful one. We predict great popularity for it.

MR. F. HOLLYER'S EXHIBITION OF PLATINOTYPE REPRODUCTIONS.

At the Dudley Gallery, Piccadilly, Mr. F. Hollyer has gathered together considerably over 200 of his platinotype reproductions of pictures by ancient and modern masters, and a few present-day artists who aspire to attain the latter rank. Both as examples of the elasticity of power which photography has in reproducing in monochrome the relative tone values, the predominant effects of lighting, atmosphere, and of course the subtleties in composition of a painter's work, as well as an attestation of the remarkable suitability of the platinum-printing process for the purpose, Mr. Hollyer's Exhibition is especially interesting to photographers.

Of this "picture copier of the first class" as Mr. H. P. Robinson, with somewhat scanty justice, thought fit to call Mr. Hollyer, Mr. Horace Townsend has the following remarks in the catalogue to the pictures:—

"In these days of overabundant art slang and studio jargon it is difficult to define simply, satisfactorily, and yet convincingly, an artistic position; but it seems at least plausible to advance the thesis that the elevation of picture-copying from a mechanical process to an artistic method necessitates the bestowal upon the reproduction of a portion of the reproducer's personality.

Here it is, I think, that Mr. Hollyer's work is in especial heedworthy, if not absolutely epoch-making as regards the history of photography.

To me at least, in the interesting series of reproductions he has for the first time brought together, there is abundant evidence that, apart from all questions of technical excellence, there is here to be found in each example, however widely differing may be the methods of the original creators, the strenuous note of his own individuality. In each case, however, this harmonises and makes no discord with the exemplar.

How this personal element can assert itself in defiance of the rigid bonds of what would appear to be so purely scientific or mechanical a process as copying a picture by photographic methods, is an inquiry perhaps as bootless as it would be involved and curious. Those, however, who are in a measure acquainted with the practical procedure of photography, and nowadays these are no few, may be reminded that there are three points at least in that procedure at which the artistic individuality of the operator may over-ride his mechanical limitations—namely, the focussing, the developing, and the manipulation of the printing from the negative.

The charge has, and not without foundation, been brought against Mr. Hollyer's reproductions that there is in them not only the original artist but a suggestion of Mr. Hollyer himself, and this in spite of the fact that there is absolutely no retouching of the negative. So far from looking upon this as a defect it seems to me to be the differentiating touch which elevates his work from a process into an art."

Of the pictures in which, to our thinking, Mr. Hollyer is most successful in reproducing, Moreland's *Stable*, Hobbema's *Avenue*, and the small collection from the recent Exhibition of the new English Art Club in the same room, deserve particular notice. The portrait *Study* of Prince Trouvetski is an especially happy example of the way in which Mr. Hollyer has preserved the lights and tones of the original. Among the miscellaneous collection are copies of works by Dawson, Rubens, Etty, Rosa Bonheur, Reynolds, Corot, da Vinci, Raphael, Velasquez, &c. There are eighteen copies of Rossetti's pictures, many of which are familiar to the students of the contents of printsellers' windows; sixty of Burne Jones's; forty-five miscellaneous subjects by G. F. Watts, together with thirty-eight of the latter artist's well-known portraits, and many other subjects. In few if any of these reproductions has Mr. Hollyer failed to prove that, as a master of photographic *technique*, applied to copying purposes, he is *facile princeps*, while it is just as obvious that he is animated by the soundest artistic judgment. Mr. Hollyer's Exhibition should do much to popularise platinotype reproductions, in preference to the almost too-prevalent cheap photogravures and etchings of well-known pictures.

EXTRACT FROM THE DAILY PRESS ON THE PHOTOGRAPHIC EXHIBITION.

[*St. James's Gazette.*]

One photographic exhibition varies but little from its fellows, and as each successive one comes round the same expectations are aroused, and disappointments ensue; expectations aroused by the continuous energy displayed by manufacturers of apparatus, and by the public in making use of the same; disappointments caused by the slow advances apparent in the standard of production, and the still more tardy march of the professionals towards an artistic sense. At the Exhibition of the Photographic Society of Great Britain, now open in Pall Mall East, one would hope to find, if anywhere, improvements apparent in both of these. But this is not to any extent the case. There are, undoubtedly, many examples of mechanical achievements—enlargements which cover such areas that no single piece of paper is large enough to carry them, as ill-disguised joints testify; visions of the growth of such evanescent creations as clouds, of interest, beauty, and use; photographs printed on paper so as to convey the deception of being works painted by hand. But alongside of this there is much that is terrible to the artistic eye, and which, conceived with the idea that it is artistic, can only warrant its reception here to mastery over mechanical difficulties. Such are the unnatural *tableaux vivants*, the stagy interiors with ill-assorted figures, the portraits of nymphs, shepherdesses, and children mast-headed, which we may expect to find held up for admiration by the tout outside the shilling photographers' in the Euston-road, but not by the premier Society in England. In landscape and architecture, which admit of little posing, and which are, we imagine, principally the work of amateurs, the results are better. Attention in this departure may be directed to the works of Karl Greger; Colonel Gale; H. J. Godbold, whose *Rocket to the Rescue* is most interesting; B. Gay Wilkinson, who received a medal, but whose work appears to be lacking in detail (*vide*, *passim*, *Westminster*); W. R. Cassels, who portrays a delightful reminiscence of a Mentone valley; Henry

Little, with a remarkable bromide enlargement of the Vatican Library; U. French; Mrs. Main; and W. Thomas. Nor must the interesting and instructive series of lantern slides, illustrating *Bees and Bee-culture*, by T. E. Freshwater, be overlooked. It is said that the Society is at present disturbed by the action of a certain section of its members who are not satisfied with the quality of some of the work admitted to its Exhibitions. We are not surprised to hear this.

Our Editorial Table.

Photographic Chemicals.

By Messrs. Harrington Brothers, Cork.

This well-known firm of chemical manufactures have sent us samples of pure chemicals specially prepared by them for the use of photographers. Among these are sulphite of soda, oxalate of potash, acetate and carbonate of soda, and similar productions in every-day use. We have found them quite pure and good.

Messrs. Percy Lund & Co., of Bradford, have submitted to us a panoramic album for photographs, its distinctive feature being that the photographs do not require mounting, but may be placed in small slits made at the corners. It should prove useful for holding a series of small prints for carrying in the pocket, &c.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

October 6,—Mr. Thomas Bedding in the chair.

Mr. E. J. Wall presented Eder's book on emulsion-making to the library. A letter from Miss C. W. Barnes was read, in which she expressed gratification at her recent election as an honorary member of the Association. It was stated that the display of members' slides at the Photographic Society's Exhibition would take place on the evening of Wednesday, November 7.

Old Wet-plate Negatives.

Mr. C. Goodwin Norton exhibited a collection of wet-collodion negatives taken in Portugal in the years 1858–63 with an ordinary achromatic meniscus lens of 12 inches focus, the stop used being a quarter of an inch in diameter. The apparatus was carried on the backs of two mules, water having to be fetched from a distance of four or five miles from where the exposures were made. The exposures averaged two minutes in bright sunshine, and the negatives were the work of a chief engineer on a railway, who chose photography as a means of sending home his weekly reports of the progress of the works. Mr. Norton said he would endeavour on a future occasion to bring up for comparison prints from the negatives made at the time, as well as others more recently made.

Prints from negatives taken of groups of the members assembled at Hampstead on October 1, by Messrs. Bridge and Weir Brown, were shown.

Mr. T. E. Freshwater passed round a collection of photographs illustrative of bee-culture, and described the circumstances under which they were taken.

Questions.

The following question from the box was read: "Does a gelatino-bromide plate improve during the first few days or weeks after manufacture?"

Mr. A. Cowan said that the keeping might harden the film, but he did not know of any other way in which the plates would improve. Plates, which were known to have a tendency to frill, when kept for six months had lost the property of frilling.

Mr. P. Everitt asked whether slow plates gave less gradation than rapid plates. Captain Abney stated that slow plates gave less range of gradation than rapid, but in his (Mr. Everitt's) experience it was rather the other way.

Question No. 2: "Does glycerine in gelatino-bromide plates interfere with their keeping or other good qualities?"

Mr. W. E. Debenham thought it would make plates hygroscopic.

Relative Rapidity of Development Printing Papers.

Mr. B. Foulkes-Winks exhibited a number of prints from an average negative (which he also showed) made to ascertain the relative rapidity of the commercial bromide and other development printing papers in use. A duplex oil lamp of sixteen candle power was the illuminant, the range of exposure given being from ten to sixty seconds at a distance of two feet. An iron developer was used in some cases. In other cases amidol (the results given by which were considered very successful), hydroquinone, and rodinal were used. These developers gave considerable variety of colour. Magnesium and gas were also used as illuminants. In reply to Mr. Teape, he said that ferrous oxalate gave him the best results, but the colour given by amidol was very pleasing.

Mr. Cowan and Mr. Everitt had noticed that amidol had a slight tendency to discolour the whites of a picture, and Mr. Cowan suggested that Mr. Foulkes-Winks should repeat the experiments with clean white margins to the prints, so as to show the staining or non-staining properties of the various developers used.

Mr. E. J. Wall, in reference to the rapidities of the various papers as arrived at by Mr. Foulkes-Winks, said that he had made some experiments with the same object, but with different results, using a graduated screen of a Warnerke's sensitometer, which he thought was better than using an ordinary negative and an oil lamp, at a distance of three feet. All the papers were exposed for a certain time, and the bromide papers were developed with fresh ferrous oxalate for each print. He developed up to the very last number he could get out, and by that means calculated the speeds.

The meeting subsequently adjourned.

North London Photographic Society.—October 4, 1892, Mr. R. Tanner in the chair.—This being the first Optical Lantern Night of the season, slides were exhibited by various members, some especially being of a very high order of merit. Among the slides shown were some exceedingly rapid hand-camera shots, taken by the "Frena" camera. Being so early in the season, the quantity of work was not large, many members having hardly begun slide printing yet. Next meeting, October 18. Technical Night and nomination of Council and Officers for the Annual Meeting on November 1.

North Middlesex Photographic Society.—October 10. The Presiden (Mr. J. W. Marshall) was in the chair, and between sixty and seventy members were present.—Col. J. Gale addressed the Society and illustrated his remarks with a selection of beautiful lantern slides. The views were drawn from all parts of the country, and illustrated many different phases of rustic life and employment, and varied atmospheric effect.—sunrise, sunset, mist, snow, hoarfrost, rain, and sunshine. Among the slides were included, by special request, a number which Col. Gale had shown on a previous occasion, noticeably *Abandoned*, *Through the Driftway to the Fold*, and a number of atmospheric effects on the Sussex downs. He then exhibited a fine selection of slides by his friends Mr. Bright and B. Gay Wilkinson. Mr. Wilkinson's slides were chiefly beautiful studies of rustic scenery, and Mr. Bright's were partly marine studies and partly humorous studies of children and animals. One, of a child sitting on the sands and glowering at the camerist, caused repeated peals of laughter. A most enjoyable evening was spent, and a vote of thanks was moved in suitable terms by Mr. F. Cherry, and seconded by Mr. H. Walker, who related how, when recently on a photographic tour in the Lake district, he came across a cottager who showed him, with evident pride, a photograph of her cottage which had been presented to her by Col. Gale. The next meeting will be held on the 24th inst., when an exhibition of members' slides will be given. Ladies are invited, and visitors will be welcome.

Hackney Photographic Society.—The weekly meeting held last Tuesday was an open night. Mr. Beckett presided. It was announced that Sir Albert Rollit, who is an amateur photographer, had consented to open the Exhibition on November 15 next at Morley Hall. A discussion on hand cameras was taken up. The Chairman thought more care should be used in the selection of a picture. The Secretary said that dust was more prevented when dark slides were used, and preferred their use to magazine kind. Mr. Gosling preferred magazine if it worked. The risible faculties of the members were tickled at this, many of whom doubtless had tried a magazine camera. Mr. Gosling went on to say he thought dust could be prevented causing damage to a great extent by painting the inside of the camera with glycerine. The Chairman said that sky printing was more neglected than it should be. Mr. Barker said he used a solution of bromide of potassium, applying it to the sky to prevent the action of developer there. Mr. Hudson then showed some prints on cellodine, a new printing-out paper not yet on the market. It was claimed that a print could be toned, fixed, and washed in hot water, and mounted (with permanence) in ten minutes. Mr. Pollard asked if solution of chloro-platinite would keep. Mr. Soneau said it would. The Chairman thought a good way to use amidol would be dry, as it is easy soluble.

Holborn Camera Club—October 7, Mr. E. H. Bayston in the chair.—Mr. J. H. Avery demonstrated the working of the Platinotype Company's new cold-bath process. He hoped to show that platinum printing by this method was one of the simplest of printing processes, and that the ordinary worker with

but little spare time, and limited space and appliances at his command, could work this process with advantage. In his opinion, while the results were far away in advance of most other printing processes, it was at the same time much more easy and pleasant to work. After further comparing platinum paper with other papers, he went on to speak of the working of the new paper, which he characterised as simplicity itself; no hypo baths required, no tedious washing, and they could develop the prints in their ordinary room by either weak daylight or gaslight. Mr. Avery thought the price had stopped the use of platinotype paper amongst some amateurs. Many thought it excessive, but, if they took into consideration the superior results and the small quantity of waste prints they had, he thought they would find it just as cheap as any other paper. Mr. Avery then went on to give various points in favour of the new cold-bath process over the hot-bath process. He developed a number of prints by this new process and the use and simplicity with which the paper could be worked commended itself to all present. On Saturday last, the final outing of the year took place at Westminster Abbey and the Houses of Parliament, finishing the evening with a tea and smoking concert at the club's headquarters.

Kensington and Bayswater Photographic Society.—October 10, Mr. J. E. Hodd presided.—The following gentlemen were elected officers for the coming year:—*President:* Hon. L. M. Sinclair.—*Council:* Messrs. Bursnell, Frogbrook, Hannaford, J. E. and R. A. Hodd, and Mote.—*Hon. Treasurer:* Mr. F. A. Hahn.—*Hon. Secretary:* Mr. C. W. Brumwell 7, Lower-terrace, Notting Hill, W. The funds of the Society were shown to be in a very satisfactory condition.

Richmond Camera Club.—October 7, Annual General Meeting.—The following officers for the ensuing year were elected:—*President:* Mr. F. P. Cembrano, jun.—*Committee:* Messrs. J. H. Alabaster, A. Ardaseer, C. H. Davis, A. Hunter, F. Neville, G. W. Ramsay.—*Hon. Secretary:* Mr. P. Ennis. The President announced that the Annual Dinner would be on November 28, at the Greyhound Hotel, and that the *conversazione* would be held at the Theatre Royal, on January 9, 1893. The annual report and balance-sheet were accepted. Beginning from October 10 the meetings will be held on Mondays instead of Fridays.

THE first meeting of the Winter Session took place on the 10th inst., it being also the first meeting under the new conditions, that is to say, held on Monday evening instead of Friday, and in the larger room, to secure the use of which has been the object of the change of day. The advantages of the new room were manifest, space, ventilation, lighting, and general comfort leaving nothing to be desired. Mr. Ennis read the paper by Mr. Dawson on "Photogravure," lent by the Photographic Society of Great Britain, and the subject was illustrated by a large number of choice prints lent by Mr. Ramsay, in addition to those supplied with the lecture. The paper was interesting, but the absence of the blackboard illustrations, to which frequent reference was made, rendered some portions of it less intelligible than might otherwise have been the case.

South London Photographic Society.—October 3, the President (Mr. F. W. Edwards) in the chair.—It was announced that the President intended to offer a prize for the best picture taken on Barnet plates, samples of which, by the courtesy of the makers, were distributed, the results to be judged on November 7. Some experiences of developing with amidol were given. It was found that the developer became inert and colourless if meta-bisulphite was substituted for sulphite of soda. One member found that used with hydroquinone it produced fog, while another member had mixed pyro with success. The further discussion of the subject was deferred until the next meeting.

Brixton and Clapham Camera Club.—October 4, first Open Lantern Night of the season.—The rain, which fell in torrents during the evening, somewhat spoiled the attendance, only seventeen members being present. Those, however, who had braved the elements were rewarded by seeing some very fine slides taken on a tour in the Scilly Isles and the Land's End by Messrs. H. and T. Bartrop and J. A. Butler, several of the sea pictures evoking great applause. Slides were also shown by Messrs. T. F. Buckle and A. Howard.

West Surrey Photographic Society.—October 5, the President (Lieutenant Colonel J. Gale) in the chair.—The PRESIDENT gave a short address, in which, alluding to the work of the Society, he drew an interesting parallel between the influence of photography and books. Referring to a recent address of Sir John Lubbock, Colonel Gale showed that most of the claims made for books in regard to mental education as well as amusement could be extended to photographs. The subject of the evening was an address by Mr. Davison touching upon a few practical points in regard to photographic apparatus used with an artistic purpose. This address proved a treat, the experience of such a worker as Mr. Davison proving invaluable in various ways to those present. Subsequently a few novelties in apparatus were shown and described to the meeting. These included a new hand camera about to be introduced by Messrs. Hinton & Co., the aluminium blind-shutter, and the changing back of Messrs. Newman & Guardia, and a new hand camera made by Mr. Hawkins.

West Kent Amateur Photographic Society.—October 7, Annual General Meeting, the President (Mr. Andrew Pringle) in the chair.—The officers for the ensuing year were elected as follows:—*President:* Mr. A. Pringle—*Vice-President:* Mr. A. R. Dresser—*Council:* Messrs. Jones, Court, Taylor, Nash, Clark, Wiseman, Grant, and Pickell.—*Hon. Secretary and Treasurer:* Mr. E. Hawkins. The accounts for the last year, audited by Messrs. Clark and Wiseman, were then presented to the President, and showed a substantial balance. A discussion then arose as to what should be done with the latter, as it was not thought necessary that the Society should go on accumulating funds of this manner. It was proposed that a *soirée* and exhibition of members' work with lantern show should be given, and carried unanimously. It was also proposed that it should be held in Sidcup Public Hall in the first week of December. A Committee was then appointed of Messrs. Pringle, Hawkins, Pickell, Taylor, and Clark, to carry out necessary arrangements and report at next meeting. Prints for competition to be sent to the Hon. Secretary not later than the day before the Exhibition framed, and no unframed prints will be exhibited. Slides to be delivered on or before meeting previous to *soirée*.

Croydon Microscopical and Natural History Club (Photographic Section).—October 7, Mr. Jno. Weir Brown in the chair, the subject being hand cameras and any apparatus which they (the members) may have used, and report on the merits and defects as shown in practice.—The Chairman called attention to the club *soirée* being held, as usual, November 23, and, being the twenty-third annual *soirée*, it was hoped that members would get forward their work so that the Committee would be able to display and hang it to the best advantage. Mr. W. Low Sarjeant was undertaking the management of the photographic section of the *soirée*, so that any information required could be obtained from him. Mr. Bynoe, Messrs. R. & J. Beck's representative, then kindly exhibited and demonstrated the use of their new "Frena" hand camera for films, taking 3¼×3¼, weighing complete three pounds. Mr. Tottem, Messrs. G. Houghton's representative, also kindly showed the working and uses of the "Shuttle" hand camera, which was adapted for plates and films, the quarter-plate weighing four and a quarter pounds with plates and three pounds with films. Mr. Low Sarjeant also exhibited two hand cameras. Messrs. Walker and Carter and several other members showed hand cameras.

Birmingham Photographic Society.—Mr. A. J. Leeson in the chair.—The Assistant Secretary read a letter he had received from the President (Sir J. B. Stone) and which was a reply to the congratulatory resolution adopted at the meeting of the Society held August 23. Two new members were elected, and one nominated for election. Mr. E. Underwood then delivered his paper on the *The Manipulation of Gelatino-chloride Paper*. [see p. 663.] Mr. Underwood, in addition to his paper, gave a demonstration which was of a thoroughly practical nature. The squeegeeing of the prints on to ground glass, stripping them off, &c., was illustrated and explained in such a remarkably explicit manner as to call forth the admiration and thanks of the members present. In the discussion which followed, in addition to the chairman (Mr. A. J. Leeson), Messrs. A. Jones, J. T. Mousley, J. H. Pickard, J. Simpkin, E. Winn, and others took part. This being the first meeting held in the new club room, the chairman announced "that the meetings at the Midland Institute would be discontinued. In future the whole of the meetings (with the exception, perhaps, of one or two large lantern displays) would be held in the new room. The old club-room, which is far too small for the requirements of the Society, will be used as a library and reading-room. The fact of all the meetings being held in one place would, he was sure, still further increase the attendance of the members, and add to the success of the Society."

Bolton Photographic Society.—In connexion with the Bolton Photographic Society, an exhibition of slides was given in the Spinners' Hall, St. George's-road, on Tuesday evening, October 5, by Mr. W. Banks, Corporation-street, the occasion marking the commencement of Society's gatherings to be held during the coming winter at their rooms in Rushton-street. The slides exhibited were the present season's by some of the largest firms of photographers in the country, such as York, Valentine, Wilson, &c., and also by members of the Society, and as each in turn was thrown on the canvas by the means of a powerful oxy-hydrogen light they proved to be a very artistic collection. Some views in Iceland were exceptionally good, as also were those of the Rocky Mountains. Other excellent views, taken on a yachting cruise round the coast of Scotland, came in for much admiration, whilst, for the edification of the younger portion of the audience, some diverting pictures were exhibited. Dr. Barr and Mr. J. S. Roscoe, members of the Society, lent a number of slides, dealing principally with local views.

Chorley Polytechnic Photographic Society.—October 5, the President (Mr. J. T. Brierley) in the chair.—It was decided to have, during the winter months, a series of demonstrations, lantern exhibitions, &c. It was also decided to have a Society album, and that each member of the Society will be expected to contribute his share of prints with a note as to plate exposure, development paper used, &c. Also Wednesday evening in each week was fixed upon as the special time when members would be expected to meet together for exchange of ideas, social chat, &c.

Lewes Photographic Society.—At the Monthly Meeting, October 4, Mr. J. Tunks (the President) gave a demonstration in making lantern slides, developing with amidol, which was followed by a discussion. It was announced that the quarterly certificate was taken by Mr. G. J. Wightman, with a landscape in platinotype.

Midland Camera Club.—Annual General Meeting, October 7, the President (Dr. Hall-Edwards) in the chair. The annual report showed that during the year fourteen general meetings had been held, with an average attendance of twenty-eight. The silver medal for the best excursion picture was awarded by the Judge, Mr. F. P. Cembrano, jun., to the late Hon. Secretary, Walter D. Welford, for a shot in the "Frena" hand camera. The present strength of the club is seventy-eight. The Council regretted that, owing to pressure of work, Mr. Welford would be unable to continue as Hon. Secretary. The Hon. Treasurer's statement showed a small balance to the good. Commenting upon these reports, the President considered that, though they might perhaps have done more, yet the work of the first year was eminently satisfactory. There were always difficulties in working a new club, members not knowing each other, a lack of interest, &c., but he considered they had gone along very well. The average attendance of twenty-eight out of seventy members was good, and he instanced a meeting of a medical society the night before, and an annual meeting, too, 300 strong in membership, with an attendance of only ten. Referring to the new rooms, he thought the members would agree that their club-room upstairs was extremely comfortable and convenient of access, whilst the library in which they were then seated, and which would be used for all large meetings, lantern shows, &c., was one of the most comfortable rooms in Birmingham. Considering the loss occasioned by the removal of the club room, and the preliminary expenses of the club, the Treasurer's balance-sheet was quite as good as could be possibly expected. The following officers were then elected for 1892-3:—*President:* Dr. Hall-Edwards.—*Vice-President:* Rev. J. Henry.—*Council:* Mrs. Welford, Messrs. R. J. Bailey, Frederick Iles, H. R. Leech, M.R.C.S., H. Roland White.—*Librarian:* R. J. Bailey. *Hon. Treasurer:* Mr. Sam G. Mason.—*Hon. Secretaries:* Messrs. C. Jervis, Fowler, and Frank H. Mason.

Oxford Photographic Society.—October 4, Annual General Meeting. Mr. Ryman Hall (President) in the chair.—The report, read by Mr. Bellamy, showed that sixteen members had been elected during the year, one member, Mr. H. C. Hull, had died, and there had been four resignations. Nineteen ordinary meetings had been arranged, including Mr. Paul Lange's lecture on "Norway," the proceeds of which, amounting to 15*l.* 10*s.*, were handed over to the Radcliffe Infirmary. Excursions had been made to places near Oxford, and conversational meetings had been held. The average attendance showed a decrease on the two preceding years. Two competitions had been arranged, but were not decided. A commencement had been made in the formation of library set of slides for loan to members, and about sixty had already been presented. At the beginning of the year the Society was affiliated with the Photographic Society of Great Britain; under this scheme many privileges were secured to members. The report acknowledged liberal donations towards the furnishing of the rooms, and concluded by reminding members that, by a mutual agreement, the rooms of the Photographic Society of Great Britain, and of the Birmingham and Cheltenham Societies, were available for use by members of this Society. The President remarked that the present state of affairs was not satisfactory, and, unless they had a considerable increase of members, they could only improve their current account by increasing the subscription from 7*s.* 6*d.* to 10*s.* 6*d.* Mr. Ryman Hall was elected President, and Messrs. A. F. Kerry, M.A., and J. H. Salter and C. C. Cole, Vice-Presidents, the name of Mr. W. W. Fisher being added in place of that of Mr. A. F. Stanley Kent, who had removed to London. Mr. R. A. R. Bennett was elected Hon. Treasurer vice Mr. Minn, resigned; the Hon. Secretaries were re-elected, and Messrs. W. J. King, G. W. Norton, A. Robinson and G. Smith, were re-elected on the Committee, Mr. Jenkins being added in place of Mr. H. M. Phillips (Ch. Ch.), who had left Oxford, and Mr. Fortt in place of the Rev. W. H. Price, M.A., Trinity, resigned, and Dr. M. D. Stark.

Rotherham Photographic Society.—October 4, Annual Meeting, Dr. J. B. Baldwin (President) in the chair.—The Hon. Secretary (Mr. Hemmingway) presented the third annual report of the Council, which expressed the opinion that the Society had shown unmistakable signs of progress. The membership had increased, the class of work done had improved in quality, and there had been a better attendance at the monthly meetings. The average number of members present each evening was fifteen. Particulars of the business of the twelve months were given. The excursions had been four in number, viz., Comsborough and Sprotborough, Haddon Hall, Wyming Brook and Rivelin, and Wingfield Manor. The event of the year had been the exhibition in St. George's Hall on February 23 and 24, and a most gratifying success rewarded the efforts put forth. The very friendly relations with the Sheffield Photographic Society had been maintained, and several of its members sent pictures for exhibition. The Council realised the help its near neighbour could render, and considered that a general scheme of federation at no very date might prove of mutual benefit. Members were urged to manifest an increased interest in the Society, the Council believing that with a little energy it was possible to attain to much higher things than had yet been accomplished, and to make the organization in every way representative of the district, which has a population of about 60,000 inhabitants. The report, together with the financial statement, which shows a small balance in hand, was approved. Officers were elected as under:—*President:* Dr. J. B. Baldwin.—*Vice-Presidents:* Messrs. E. Isle Hubbard, W. H. Hayward, and G. T. M. Rackstraw.—*Council:* Messrs. I Wright, W. H. Shepherd, W. Mason, J. W. Whittington, and A. B. Clarke (Rawmarsh).—*Treasurer:* Mr. J. Leadbeater.—*Hon. Secretary:* Mr. H. C. Hemmingway. The programme for the coming season was discussed, the principal item being the holding of an exhibition early in the new year. The optical lantern was afterwards brought into use, and a profitable hour was spent in criticising slides made by the President, Messrs. E. Isle Hubbard, G. T. M. Rackstraw, J. Leadbeater, W. Mason, J. Clarke, and H. C. Hemmingway.

Sheffield Photographic Society.—October 4, Annual Meeting, Mr. B. J. Taylor in the chair.—The Treasurer presented his report, which showed a substantial balance in hand, and was considered very satisfactory, and duly passed, after which the Secretary gave his general report of the proceedings for the year, showing that there had been four resignations and eight new members, that the Society had more members on its books than ever before, that it was altogether in a prosperous condition, and that the proceedings throughout the year had been characterised by each member being anxious to promote the general good of the Society. The excursions had received considerable attention and support, and had produced some splendid work. The officers for the ensuing year were elected as follows:—*President:* Mr. B. J. Taylor (elected for the fourth time).—*Vice-Presidents:* Messrs. G. Bromley, T. Firth, and E. J. Chesterman.—*Council:* Messrs. W. T. Furniss, J. Smith, T. G. Hibbert, W. M. Toplis, and E. Sampson.—*Reporter:* Mr. E. H. Pearce.—*Treasurer:* Mr. Bradley Nowill.—*Secretary:* Mr. E. Beck. After votes of thanks to the retiring officers, the members taking part in the photographic exchange produced their pictures, making in all nearly 300 prints.

Edinburgh Photographic Society.—October 5, Mr. H. J. Blanc, A.R.S.A., &c., in the chair.—The principal business was a discourse by Mr. A. Mann, M.A., on *Telescopic Photography*, in the course of which he stated that this was a subject to which he had turned his attention about eight years ago, and one which had acquired more prominence during recent months through the introduction by Mr. T. R. Dallmeyer of a special new lens for this purpose. The speaker disclaimed any intention of discussing the merits of that instrument, which would doubtless find many useful applications; his desire was rather to show how satisfactory photographs of distant objects could be produced by means of lenses possessed by most photographers, amateur and professional. He expressed astonishment that the subject had not received attention much sooner; for, although the expensive appliances for celestial photography might be quite out of reach of the ordinary workers, yet no obstacle stood in the way of dealing with objects on the earth's surface. The instrument by which most of his experiments in this direction had been made was a small pocket telescope by Dallmeyer, his method of use being to dispense with the ordinary objective and attach the telescope itself to the front of the camera, fitting it into a new portable front he had made—of course, at right angles to the focussing glass. The telescope is fastened—light-tight—at a point distant about one-third of its length from the eyepiece. Before fastening it, he found that, although the instrument could be used of the full length, and as it was, yet it was a great improvement to remove the two inside lenses placed in such instruments a little in front of the eyepiece for the purpose of reversing the image. This, he showed, could be very easily done without injuring the instrument, those two lenses being fixed to one tube, and removable in a moment. The eyepiece is then pushed forward into the place previously occupied by them, which shortens the instrument by about one-third of its length. Three important advantages are thus gained. The telescope being much shorter, the leverage on the front of the camera is reduced, four reflecting surfaces are got rid of, and the width of angle embraced by the instrument is doubled, while the magnifying power is still quite sufficient. One thing requiring special attention is the prevention, as far as possible, of all superfluous light from passing through the camera. When the object-glass of the telescope, which is about twelve inches focus is unscrewed from it and placed in front of the camera, the image on the focussing screen is seen to be a circle of about ten inches in diameter, and it behaves exactly in the same way when placed in the telescope tube. The reversing lens or eyepiece which has to receive the image is only half an inch in diameter, and can only deal with a circle of that area; and, as the area of the one circle is just four hundred times that of the others, it follows that only one-four-hundredth part of the light entering the telescope is utilised in forming the image, the other three hundred and ninety-nine parts tend only to do mischief. This great cone of light strikes against the sides of the tube, and a portion of it is reflected through the eyepiece into the camera, and tends to fog and enfeeble the image on the plate. The most effectual way of dealing with this evil—an evil which applies to all kinds of telescopic arrangements—is to place a blackened board tube of sufficient length in front of the telescope, to cut off all light save that which comes from the object which is being photographed. Such a tube is easily extemporised. For focussing the telescope, the method he preferred was to take it to his eye and focus accurately upon the distant object wished to be photographed, and then draw back the eyepiece a short distance, say a quarter of an inch, before inserting it in its place in the camera. If this is not done, the focus will be much too long for any ordinary one. The camera is then moved out or in until the image is in sharp focus; the nearer the eyepiece is to the object-glass, the larger will the image be on the focussing screen, and *vice versâ*. Another mode of getting the focus is to rack the camera to a suitable length, and varying the distance between the eye and object-glasses of the telescope. A telescopic arrangement for photographic purposes consists essentially of two parts, viz., an object-glass (which may either be a single lens or a combination of lenses similar to those used for ordinary purposes) to form an image of the distant object, and a smaller lens of very short focus placed a little behind that image for the purpose of reproducing it. This arrangement combines the action both of the ordinary photographic camera and that of the magic lantern, so that it can do the work of a whole battery of lenses of different focal lengths, enabling the operator to photograph a distant object to any scale from the same position. As an illustration of the capabilities of this arrangement, the lecturer stated that some time ago he had photographed the gilded figure on the top of the University buildings from a distant window by means of the small telescope already alluded to attached to a whole-plate camera of the ordinary dimensions, and that he had thereby obtained an image six inches in height, while the ordinary lens of the camera, a rectilinear of eight inches focus, gave an image of only a quarter of an inch in height from the same position; so that, to have produced a negative in the ordinary way of the same size, a lens and camera would have been required twenty-four times that of the rectilinear lens, which would have amounted to one hundred and ninety-two inches, or sixteen feet, of a camera from lens to plate. Mr. Mann showed a portrait taken by him with the same apparatus seven years ago, which he said showed fairly sharp definition on the lantern screen, even when enlarged to several times life size; also a telescopic combination suitable for more rapid work, which he had extemporised out of a rapid French portrait lens working at *f*·3 and the eyepiece of a small telescope fitted inside the camera for delineating the image formed by the portrait combination. A short cylindrical tube was fixed to the inside of the camera front of sufficient diameter to admit of the portrait lens being racked in and out, and into the end of this tube was fixed the eyepiece; the focussing was performed by the rack arrangement of the portrait lens, which enabled the image produced (in air) to be placed at any desired distance from the eyepiece. Reference was also made to some of the uses to which such a contrivance could be put, inasmuch as interesting studies of wild animals, sharp photographs of ornaments or designs in the upper parts of buildings and other inaccessible places could be secured from a distance at which they are quite invisible to the naked eye. At places of public resort any one posted on some coign of vantage could command the surrounding district and photograph what and whomsoever they pleased, while in military operations an enemy's position could be surveyed and photographed from a point beyond the range of his guns. A short discussion followed, and Mr. Mann received a cordial vote of thanks for his communication.

Correspondence.

THE LANTERN POLARISCOPE.

To the EDITOR.

SIR,—I beg to offer you a few remarks upon the article by Mr. G. Baker, which appears in your last issue, October 7th (see page 2, *Lantern Supplement*). For many years I have been experimenting on projections and made numerous lanterns here for trial, before placing the work out to be made in a final and presentable form.

I have also had in my hands the counterpart polariscope (by Ahrens)

of Mr. Spottiswoode, which is the property of Mr. Crisp. The results arrived at are these. Mr. Spottiswoode's form of polariscope is now quit "out of the running." My own will not only show numerous results and phenomena not possible with the older apparatus, but also on a far larger scale. A 20 ft. disc of great brightness is attainable by means of the electric light, and suitable lens.

I have been able to show that very fair results may be obtained with limelight; indeed, for experimental research and exhibition the electric light is essential for the polariscope, hence apparatus and means can be employed wherein much light is lost without any inconvenience. Consequently I have used polarising Nicols no larger than ¾ in. in diameter (having a clear way of only ½ in.), giving results not inferior to polarising prisms of 2 or 3 in. diameter. The method is to draw down the large condenser beam, then parallelise it forming a small beam of ½ in. diameter after passing the polariser, this beam is again expanded and parallelised to form a beam of 2 in. diameter, or more if needed. The whole polarising apparatus may be made for 5*l*., and working may be direct, with all the advantages of a large Nicol, no longer to be obtained for love or money. Regarding incandescent 100 candle power (and less power) focus lamps, I would advise no one to use these. With the 100 candle power lamp, nearly half-horse power is converted into heat, and slides will be broken one after the other; the lantern becomes so hot as to be dangerous in a very short time.

I have tried every possible expedient to overcome the difficulty. Of course nothing will prevent the heat of the lamp being generated, but water-screens may be employed to shelter the slides, and lanterns may be enlarged and better ventilated. After making lantern after lantern, and many water-screens, I reached a point where the lantern became a sentry box, into which I could hide myself, and the water-screen a volume of water sufficient to cook an Irish-stew for a small family. Finding that the end in view had not even then arrived, I gave this matter up. However, the lantern was used for some time as a drying cupboard, and for producing warm water. I also was lent a lantern made by Messrs. Steward constructed especially for these focus lamps. But I failed to find the difficulty eliminated, and returned them the lantern as useless in my estimation. In saying this I do not wish to do an injustice to this firm. The lantern was made to the pattern of a customer, so that they were not responsible for the result. Messrs. Steward's lanterns are so well known that it is not likely that I should attempt to disparage their work. My own triple, built by them, is perfection itself.

There is no doubt whatever that the arc light is the right thing in the right place when inside a lantern, and, after all, the additional expense is not large. The same, or even more, horse power is utilised in forming the arc than in incandescing the filament of a 100 candle power focus lamp, yet it must be remembered that light giving rays are produced in the far larger quantity than the heat giving rays, *i.e.* more yellow and blue rays; in the other case the red rays predominate. To put the matter generally and briefly; for a small arc lamp using the same current as a focus lamp, about ten times more light is produced, hence, in round numbers, the focus lamps give ten times more heat. These figures are not accurate, only sufficiently approximate to give a general idea. It is evident, therefore, that all being equal for the same current, a focus lamp gives ten times less light and ten times more heat than the arc lamp. Possibly these remarks may interest some of your readers.—I am, yours, &c.,

DAVID SALOMONS.

Broomhill, Tunbridge Wells, October 8, 1892.

THE EXPANSION OF AMMONIA SOLUTION.

To the EDITOR.

SIR,—My attention has been called to Mr. Haddon's criticism of my article on ammonia in *Dry Plates*, the monthly magazine of the firm of Cadett & Neall. Let me begin by saying I am quite ready to learn from those who know better than myself, and, if Mr. Haddon is right, I can only offer him my best thanks for his correction. I would, however, first point out the disclaimer in my paper where I mentioned that the statements are not original with me. I have simply done what Mr. Haddon himself has done, and quoted from tables by chemists of repute, and accepted their statements as correct, without any personal proof.

I am at a disadvantage in taking Mr. Haddon's criticism from the abridged reports of the journals, as I was not at the meeting;* he must therefore kindly make allowance in what I am going to say in case I am under any wrong impression.

My authority for the statements in my paper is the late Mr. John Joseph Griffin, F.C.S., in his work, *The Chemistry of the Non-Metallic Elements, the tenth edition*. Of course, the work is rather out of date; but, considering that many of the latest books quote from tables much older, I need not apologise on this score. Mr. Griffin was (and the firm still is) the maker of the "Ammoniometer." Thousands of these have been sold and are in use all over the world. Mr. Griffin gave considerable personal attention to the testing and analysis of ammonia in a large commercial way, and he gives directions in his book for: Determination of the chemical strength of liquid ammonia; determination of the strength of ammonia by the ammonia-meter (hydrometer); preparation of liquid ammonia of particular degrees of strength for testing and other purposes.

* The report given in this JOURNAL was an *unabridged* one.—ED.

Now, no human being is infallible, I know that personally *very well* but I may, I think, be forgiven for taking an authority, who perhaps had the greatest experience in the commercial testing of alkalies and acids in the United Kingdom, and I must confess, that until I have tested, personally, Mr. Griffin's tables, or have had further evidence that his statements are wrong, I shall not lightly surrender him as an authority.

Though, until now, I have never doubted Mr. Griffin's statement, "ammonia has the remarkable property of possessing the same bulk in all its combinations with water," I have always been aware of the great discrepancy between various authorities in s.g. tables of *all kinds*, and I have often wondered at it, but doctors will never agree, even in matters one would suppose to be simple facts. I have not Watts' Dictionary, but I presume that the statement, that liquid ammonia of a s.g. of ·884 contains 36 per cent. of real ammonia, is from Carius. It must not be forgotten that Carius was at variance with Roscoe and Dittmar on the important question of the amount of absorption of NH^3 at various pressures, and therefore his s.g. tables may be open to question.

Mr. Haddon has very kindly (and I am sure we all thank him) taken the trouble to put the expansion question to practical test; but he has left one important part undone, he did not verify or question the s.g. table in Watts', neither did I question Griffin's tables, so we may both shake hands on that point.

Let us now turn to the practical side of the matter. An expansion 0·37 per cent. (as per the journals) is, for all practical purposes, a very small matter indeed, and, if Mr. Haddon makes his curve on the data of his experiments, he will be close enough to a straight line to satisfy any photographer's faith in the ammoniometer. The so-called 20 per cent. error in reading strength is purely one of variance in a.g. tables, and, whether right or wrong, does not in any way affect the relative testing with the ammoniometer to an appreciable degree. If the dilution to the extent carried out by Mr. Haddon only gives 0·37 per cent. expansion, how much less must be the expansion between samples of ammonia high in strength!

It becomes mere *straining at a gnat*. I do not say that Mr. Haddon is wrong; but, as he makes the expansion so little, it would be well for him to test the question again under most careful conditions as to the temperature. Surely a curve made on the results of his experiments would scarcely agree with the s.g. tables in Watts' Dictionary.

I will, when not so busy, put the matter to a practical test. Griffin's s.g. table gives for s.g. ·884 a percentage of 31·9 at 62° F. against Watts' 36 per cent.; some one please say who is right; there surely should be some table up to date; however, from a practical point of view, I do not find sufficient reason for Mr. Haddon's experiments to prevent photographers from testing their ammonia, as recommended in my paper. They will not, in any case, be more than a small fraction per cent. in error, one that they would hardly notice in measuring.

An article by Mr. Haddon on ammonia would be much appreciated by us all, and not the least by, yours faithfully,

JAMES CADETT.

Cadett and Neall Laboratory, Ashtead, Surrey.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the EDITOR.

SIR,—There are various reports as to the state of business amongst photographers during the past season, but those who are in the best position for knowing tell us that the winter outlook for assistants, at any rate, is a bad one. This being so, may I say a word about the "Benevolent," and the claim it has upon photographers?

In various recent cases of distress local efforts have been made and special subscriptions raised, without any appeal being made to the Benevolent Association, the committee of which has usually heard of the case when too late to be of use. As the Association is always prepared to grant prompt and practical relief, not only in money, but also in that help which is often better than money, no man who knows of a deserving case need be afraid to make application. In every case the Association makes the most careful inquiries, but treats the particulars in strict confidence. Where a loan will afford the necessary relief, the grant is always made in that form, and it is satisfactory to subscribers to know that in some cases men who have been entirely broken, financially, have been so firmly set on their feet by the Benevolent as to be able to pay back every penny advanced, so that an excellent work has been done without any real expenditure of the funds.

In connexion with the work of the Association there is an Employment Bureau, upon which we have at present the names of a large number of assistants of almost all classes, and some of them very good men, who are seeking situations. Employers who want assistants will greatly help the work of the Benevolent if they will make application to—yours, &c.,

THE SECRETARY, *Photographers' Benevolent Association.*

Memorial Hall, E.C. October 10.

NEGATIVES FROM NEGATIVES.

To the EDITOR.

SIR,—Referring to your article in this week's JOURNAL, October 7, 1892, in reference to reversed negatives, or rather a negative from a negative, as the process is more generally called, I, being in some doubt

as to the success being due to ferrous-oxalate development, I exposed two plates, one Ilford, one Britannia, and developed them with a pyro soda developer. I herewith enclose you the result, with the original negative for comparison. I may say that these negatives are a fair sample of the results obtained. The exposure was eight seconds to fairly good daylight through the studio window. My opinion is the success is in the exposure, for this reason: If you begin with a short exposure, you obtain a transparency; continue the exposure, you get a negative; further expose, and you again find you have a positive; and these changes undoubtedly occur many times over. The chemical action being the same, it must be caused by some reversing action of light on the silver salt. A very good plan to observe these changes is to cut up a few plates—say a dozen pieces, two quarter-plates, six out of each—and make one dozen exposures, beginning at one second, and each time increase as, say, 1, 3, 5, 7, 9, and so on; then develop them and see the result. It is very simple, and the time spent in developing will not be thrown away. The developing is longer than for an ordinary negative. If carefully done, the experience gained will teach a great deal that is useful. The same thing can be done with gelatino-bromide paper, and the change from positive to negative will occur.—I am, yours, &c., E. Frewino.

26, *Eden-street, Kingston-on-Thames, October* 10, 1892.

[The examples of the process our correspondent sends are exceedingly good, it being difficult to differentiate between the original and the copies.—Ed.]

PROPOSED PHOTOGRAPHIC SOCIETY FOR GREENWICH.

To the Editor.

Sir,—I beg to inform you that a meeting will be held at the Lecture Hall, Royal Hill, on Wednesday, October 19, at eight p.m., at which Mr. E. W. Maunder, F.R.A.S., will preside, to consider the advisability of forming a Photographic Society for Greenwich, and to arrange the necessary business details.

It is hoped that you will find it convenient to attend and support the scheme.—I am, yours, &c., Leon. I. Atkinson,

193, *Greenwich-road, S.E.* *Hon. Secretary* (*pro tem.*).

THE PHOTOGRAPHIC EXHIBITION.

To the Editor.

Sir,—I am instructed by the Council to inform you that they have determined to endeavour to obtain yearly a selection from the pictures in the Exhibition such as shall show the progress of the art from year to year.—I am, yours, &c., R. Child Bayley, *Assistant Secretary.*

Photographic Society of Great Britain, 50, Great Russell-street, Bloomsbury, London, W.C., October 12, 1892.

MR. HUBERT AND "UNFORTUNATE."

To the Editor.

Sir,—It would have given me great pleasure to reply to your correspondent, but for the simple reason that "Unfortunate" preferred to hide his lights from my expectant gaze. It may be that so many employers, jealous of my opportunity to possess such a boon, offered him work, that forthwith he went to the highest bidder.

However, it seems to me only right to mention that the printer I engaged in his place on the whole turned out very satisfactory, and is with me now. He was one of those not above being taught, and after I explained the different processes scientifically, which previously he performed in a hap-hazard way, he has now managed to reconcile me to the loss of the other, whose conscience may perhaps be awakened by the renewed correspondence. If he will name his employer, I will forgive; but woe to the latter if I meet him.—Yours, &c., J. Hubert.

238, *Mare-street, Hackney, Oct.* 2, 1892.

SMELL OF THE OIL LANTERN.

To the Editor.

Sir,—In your new "Lantern Record," which I hope will be much appreciated, you allude to the old grievance of the smell from the oil lantern (page 1, Lantern Supplement).

If you remember, I some months ago sent you my method of avoiding this trouble.

From a continued experience and some dozens of trials, I am quite convinced that all unpleasantness may be avoided by following out this plan, viz., never leave in the reservoir or the wicks any oil; to do this after your entertainment is over, and the lamp turned out, immediately empty the reservoir, then relight the wicks, and let them burn *quite out*, by which means all oil is removed from the wicks and lamp.

Do not recharge the reservoir until you are ready to show your slides. The wicks will simply want a rub with a cork or soft pad.

I should not trouble you with this if I were not so satisfied with the result of my discovery.

What was a constant course of annoyance and a deterrent to using the lantern has quite disappeared.

I constantly show to my friends, in a small room, slides with the greatest ease and pleasure. So badly was I annoyed with the murky smell before making this alteration, in working the lantern for parlour showing, that I was contemplating abandoning the use of it. No carefulness in cleaning, wiping, putting in new wicks, or anything else will be so efficacious as this method I have described. Of course, use the best crystal oil, and don't turn up your wicks too high.—I am, yours, &c.,

Camera Club, October 8, 1892. Frank Howard.

DISCOLOURATION OF AMIDOL SOLUTION.

To the Editor.

Sir,—I shall be much obliged if you can give me some advice as to mixing amidol so as to get it to keep.

I have tried the developer with both under and over-exposed negatives, as well as some I believed to be correctly timed, and like it very much.

I find, however, that it discolours in a very few days. I have mixed it in the proportions of amidol, soda sulphite and water, as recommended.

The first time I used tap water (the water is rather hard with a good deal of lime in it), boiled for about an hour, and the time allowed to settle, and poured off clear. The bottle was well stoppered and kept in a dark cupboard. On looking at it after a fortnight I found it almost black. It, however, developed all right, though not so rapidly as at first.

I then mixed some more in the same proportions, but with distilled water (got from a local chemist); and now, after ten days, it is a rich purply brown with some dark coloured sediment in the bottom of the bottle.

This is hardly what one would expect when one is told "the solution keeps well." I should, therefore, be obliged if you can give me any advice on the subject so that I may find out whether the discolouration is my fault.—I am, yours, &c., J. H.

October 10, 1892.

[The discolouration of which our correspondent complains may possibly be avoided by acidifying the sodium sulphite in solution before adding it to the amidol solution.—Ed.]

THE DANGERS OF OXYGEN MAKING.

To the Editor.

Sir,—Our unfortunate friend Mr. T. B. Walshe (see page 8, Lantern Supplement) has had a terrible experience, but a little caution would have saved him a lot of suffering. If he had placed about a saltspoonful of the mixture on a shovel, and placed it on the fire, he would have been warned of its true character. *This should always be done with a fresh batch of oxygen mixture.* Again, it is not necessary to use black oxide of manganese for its *catalytic* action, as fine sand does just as well, and the risk of having black antimony supplied for black oxide of manganese is avoided. This same mistake has been made before, with fatal results, and, if my memory serves me, it happened in Ireland.—I am, yours, &c.,

Liverpool, October 10, 1892. James Wood.

"COOL WATERS" (SHOULD NOW BE "HOT WATERS").

To the Editor.

Sir,—Mr. Whitfield's letter in your last issue clearly shows that he is determined not to be convinced that we *did not* endeavour to pass the picture off as our own production, either by suggestion or otherwise.

To continue harping upon the same false string with such blind pertinacity is, to say the least, irritating after the overwhelming evidence brought forth disproving the entire accusations.

The sweet benevolence in reminding us that it is not yet too late to apologise—for something we had *not done*—is almost sublime.

Reading between the lines of the whole of this affair, it appears to us very like a little game we believe the Yankees call "spoof."—We are, yours, &c., Morgan & Co.

Old Christchurch-road, Bournemouth, October 9, 1892.

West London Photographic Society.—Annual Meeting, 14th inst., at headquarters.

Mr. and Mrs. W. J. Anckorn received a gold medal at the late Paris Photographic Exhibition.

Photographic Club.—October 19, Demonstration of the Platinotype Company's "Magnesium Lamp." 26, Smoking Concert.

Croydon Camera Club.—October 17, *The Pictures at Pall Mall*, by Mr. Maclean; and *Intensification and Reduction*, by Mr. A. E. Isaac. 31, Lantern Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—October 20, Fire Lantern Night of the season, Judging of Competition Slides. 27, Members' Open Night. November 3, *Rapidities of Various Printing Processes* (continuation), Mr. B. Foulkes Winks.

THE Blackfriars Photographic and Sensitising Company inform us that they have been appointed sole London agents for Messrs. Walter Griffiths & Co.'s detective, enlarging, and lantern-slide cameras. The Company will also this season cater more for the lantern trade in general than they have done hitherto.

INVITATION EXHIBITION AT THE CAMERA CLUB.—An Exhibition of Pictorial Photographs, selected from contributions made by the leading artist photographers at home and abroad, will commence at the Camera Club, Charing Cross-road, on Tuesday, October 18th, and will be open free to visitors, from 10 a.m. to 12 a.m., and 2 p.m. to 4 p.m. daily, until December 8, on presentation of cards, which may be obtained from Exhibitors, from Members, or from the Honorary Secretary. The Exhibition will consist of selected pictures produced direct by means of photography during the past year.

ON Monday, October 3, while some *employés* of Mr. James Bacon, photographer, Northumberland-street, Newcastle, were at work at 20, Ridley-place, an ignition of guncotton took place. Ernest Baker, thirty-seven years of age, who was using the cotton, was burnt on the face and cut about the arms, and the back kitchen was slightly damaged. Some of the woodwork caught fire, and word was immediately conveyed to Pradhoe-street Police-station, from which place the alarm was raised at the Westgate-station. Superintendent Mathews, with a staff of firemen and the tender, at once proceeded to the place, but the fire was extinguished by a few people employed on the premises, and by some neighbours, before the fire brigade arrived.

BOLTON PHOTOGRAPHIC SOCIETY.—November, *Development of Platinotype Prints (Cold Bath)*, by Mr. S. G. B. Wollaston, and exhibition of "Key" camera work. December: General Exhibition of members' work obtained during past season; Paper by Mr. W. Collier, *A Short Trip to Brussels*, illustrated; *Photography* hand camera competition prize prints. January: Paper by Mr. W. Banks, *Slops: their Areas and Relation to Exposure*. February: Demonstration—*Printing and Toning Gelatino-chloride Paper*, by Mr. J. S. Roscow; General Lantern Exhibition. March: Paper by Mr. R. H. Abbatt, *Process Blocks and Photo-mechanical Printing*. April: Demonstration, *Photo-micrography*, by Mr. W. Hutchinson; *Photography* prize slides. May: Demonstration, *Stereoscopic Transparencies*, by Mr. C. K. Dalton; Arrangements for summer season.

THE HINTON HAND CAMERA.—Messrs. Hinton & Co., Bedford-street, Strand, have brought out a new hand, or stand, camera bearing the above designation. It is half-plate size, and is not magazine, but works with dark slides. It has a focussing screen which is always in position. This screen is seen from behind through adjustable winged doors, which close sufficiently near to obviate the necessity for a focussing cloth. By an ingenious adjustment a strong magnifying-glass is fitted just behind the ground glass, and which is capable of being brought opposite any desired portion of the screen. The shutter, situated behind the lens, is actuated by pneumatic means, and is adjustable as regards rapidity. The camera extends to a considerable range, has two finders, and numerous effective movements, which unite to constitute it a very excellent type of camera.

A DISHONEST PHOTOGRAPHER.—Frank Dudman, thirty-seven, photographer, was recently indicted for having embezzled sums of money received by him on behalf of his employers, Messrs. Hollis & Sons, photographers, of 160, High-street, Camden Town. Mr. Blackwell prosecuted. The case for the prosecution was that on the 12th of August the prisoner called on one of the prosecutors' customers, and collected the sum of twelve shillings for photographs that had been supplied, and on the 22nd he collected a further sum of six shillings, which was not accounted for. The prisoner was manager to one of the prosecutors' branch establishments in High-street, Camden Town. He left somewhat suddenly, and then wrote certain letters admitting that he had taken certain moneys, which he offered to repay on getting work. Detective Taylor, Y Division, on telling the prisoner the nature of the charge, stated that he said in answer to it "I admit it, and am sorry for it, and I intended to pay it back." He was found guilty, and sentenced to six months' hard labour.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A committee meeting was held on October 7 in the rooms of the Photographic Society of Great Britain, Mr. W. Bedford in the chair. The Secretary reported that, since the last meeting, he had received intimation through Mr. Bedford of a legacy of 52*l.* 10*s.* left to the Association under the will of the late Mrs. Emma Mary Evans. Subscriptions had been received from four new members, and small sums from two collecting boxes. One case of distress had come before the Association. The applicant stated that he had been for twenty years a photographic printer, that his last employer had been obliged to discharge a portion of his staff through decreasing business, and that he (the applicant) had been three months out of work, and with his family was on the verge of poverty. He gave four references, including his last employer, and covering about fifteen years' situations. He asked for assistance in finding a situation, or a grant of money as a temporary relief. The Secretary had made inquiries from three of the references, all of whom gave the applicant an excellent character, and failing to find for him a situation as a printer, recommended him for a different class of situation, which he obtained. On the proposal of Mr. Mackie, Mr. R. Child Bayley was elected a member of the Association; and Mr. H. W. Watts, Rangoon, Burmah; Miss Catharine Weed Barnes, New York; and Messrs. John Lewis and F. Gillard, both of Birmingham, were elected on the proposal of Mr. H. Snowden Ward. The arrangements for the lantern evening at the Photographic Society of Great Britain were fully discussed. The arrears of subscriptions were considered seriatim; various members undertook to personally wait upon certain subscribers, and the Secretary was instructed to write to the remainder.

OUTING OF MESSRS. MORGAN & KIDD'S EMPLOYÉS.—The annual outing of Messrs. Morgan & Kidd's *employés* took place last Saturday, when the party, numbering close upon one hundred, proceeded by rail to Portsmouth, and thence by tram to Southsea. Owing to the growth of the business, the number present this year was larger than at any previous outing. Upon arriving at Southsea, the party proceeded to inspect the various places of interest. Dinner was served at the Esplanade Hotel, where full justice was done to the good things provided. One of the novelties of the dinner-table was a unique invitation and menu card, designed by Mr. Durham (Messrs. Morgan & Kidd's chief artist), and executed in collotype by Mr. Berghoff, the plant for this process having recently been laid down at a great outlay. The health of Mr. and Mrs. Kidd was drunk with great enthusiasm, and a hearty vote of thanks was accorded to Mr. Kidd for his kindness in providing the day's pleasure, this being proposed by Mr. Ernest Morgan and seconded by Mr. Dennes. Both spoke of the great interest Mr. Kidd always took in his *employés*, no matter how humble the position they might hold in his establishment. Mr. Kidd, upon rising to respond, was greeted with rounds of applause, and must have been gratified at a reception which clearly showed his popularity as an employer. He thanked them all for the kind way in which his name had been received, and expressed the hope that he and Mrs. Kidd might long have the pleasure of meeting them at similar gatherings. "Success to the Collotype Department," as the latest addition to the establishment, was proposed by Mr. Dennes and seconded in an able manner by Mr. Durham, who spoke at some length upon the great future which he believed was before this department. As the party were more inclined for sight-seeing than making speeches, an adjournment was made to the beach and pier, and at seven o'clock the journey home was undertaken. Richmond was reached shortly after ten o'clock, all agreeing that a most enjoyable day had been spent and that the annual outing of 1892 would long be remembered.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange a diamond frame Safety bicycle for whole-plate camera and lens, or a good lantern.—Address, H. HOWARD, 63, Victoria-road, Aston, Birmingham.

Whole-plate landscape camera, never used, cost 7*l.* 10*s.*, will exchange for hand camera.—Address, SEWELL BRADY, Portsmouth-road, Long Ditton, Surrey.

Exchange lantern, slides, and gas bags worth 25*l.* for landscape camera, slides, and rectilinear lens 12×10 or 10×8 size.—Address, T. H. PRICE, Photo, Dursley, Glos.

Wanted, first-class hand camera, 5×4 preferred; exchange pair dissolving lanterns, mahogany bodies, four-wick lamps, tripod stand, complete in two cases, slides.—Address, H. COUCH, 11, Waterloo-crescent, Dover.

Will exchange 5×4 "Optimus" rapid rectilinear lens, Waterhouse diaphragm fitted with pneumatic (plunge) shutter, for time and instantaneous, for 5×4 "Optimus" rapid euryscope with iris diaphragms.—Address, J. K. SMITH, Little London, Rawdon, near Leeds, Yorks.

Wanted, fifteen-grain tubes chloride of gold or whole-plate mounts, in exchange for roller-blind shutter for hood one and one-sixteenth inch diameter, Watson's drop shutter for hood one and seven-sixteenth inch diameter, and Lancaster's cyclist's clip.—Address, BERNARD GREEN, Cockermouth.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPH REGISTERED:

John Hosburgh & Sons, Edinburgh.—*Portrait of Dr. Russell, Lord Provost of Edinburgh, in robes of office.*

M. & M.—See answer to T. Sohne.

C. H. OAKDEN.—We shall be glad to have the promised particulars.

J. W. MOORE.—We know nothing more of the method than that given by the author. No doubt oil of cloves is meant.

H. S. ELLERBECK (Kronstad, Orange Free State).—We have duly received the notes and will utilise at an early date. Many thanks.

R. G. asks: "Are thirty grains of citric acid too much for a ten per cent. solution of pyro?"—No. You might even increase the quantity to sixty grains.

A. Z. (Leeds).—In photographing the vault the magnesium light will be best. It will be advisable to have two or three lights fired simultaneously from different points.

WM. MCC.—If iron protosulphate fails to precipitate the gold from your phosphate toning solution, try the effect of strongly acidifying the iron solution with sulphuric acid.

FERROTYPE PHOTOGRAPHER.—I. Formulæ for iodised collodion are to be found at p. 775 of the ALMANAC for 1892. 2. Saxe paper may be ordered of any photographic dealer.

C. SACH.—Any optician will supply lenses accurately paired for stereoscopic purposes. Two lenses of the rectilinear type, taken haphazard from stock, are not necessarily identical in focus.

DOMO D'OSSOLA.—To obtain a greyer print on bromide paper than the sample sent, expose longer and develop less. Bromide does affect the colour, and for the result you aim at had better be omitted.

BISHOP says: "Would you tell how to make a collodion transfer, and oblige?"—The required information would occupy too much space in this column. Better refer to past volumes of the JOURNAL.

ROSEBUD writes: "Could you inform me of a good work on miniature painting, and are they (miniatures) in demand much?"—We know of no such work. Miniatures are only in slight demand we believe.

BELFAST.—The enlargement in question is not a single print made from one negative. It is composed of several prints—four or five—from separate negatives. But great skill is displayed in the joining.

W. R. W.—1. For portraiture, one light (with suitable reflectors) of from five to six thousand candle power will suffice. 2. So that the light falls on the sitter at an angle of about forty-five degrees. 3. Any of the commercial arc lamps.

R. A. S.—Carbon lantern slides do not require varnishing, though there is no objection to its being done. Some workers say that varnish rather tends to give greater transparency to the picture. In this case varnishing is an advantage.

R. COHEN.—The process may be practicable, but the public will, we imagine, be very chary of investing in any Company formed to work a method of producing "photographs in natural colours." We trust that from past experiences and exposures investors will be more cautious in the future.

S. ROSE.—Unless your business is very extensive in enlarging, it will scarcely be necessary to supplement your present arrangements with artificial light for the winter, considering that your work is confined entirely to bromide paper. If you were situated in London or some other large town, the case would be different.

THE NATIONAL AND PROVINCIAL PHOTOGRAPHIC AND PORTRAIT PAINTERS ASSOCIATION ask for any information as to whether there is a book published that deals with the artificial or electric light for photographic studios.—There is no separate work devoted to the subject that we are aware of. Past volumes of this JOURNAL contain all the information published in reference to it.

ANGLICAN.—If the premises were taken on a repairing lease, we do not see how the landlord can be held responsible for any damage that may arise from the wind or storms. We expect that you, as the tenant, will have to do the repairs. By leaving the building as it is, further damage may accrue in the event of another storm. We are not surprised that the landlord does not move in the matter.

T. SOHNE.—The spots on the paper are due to air bubbles at the time of floating between the paper and the solution. They are not noticeable, as you say, until the paper begins to discolour, but they are there all the same. If the paper be printed, or be exposed to light so as to give it a tint, they will then become manifest. Until the paper becomes discoloured the insensitive patches are not seen.

ST. MUNGO asks: "1. Would you favour me with some information regarding the 'Albo-Carbon Light' for retouching by at night? 2. Also, could you explain why the white round the edge of vignettes in chloride prints (aristotypes) so frequently turns yellow?"—I. The albo-carbon light will answer very well for retouching by. The light from the burner had better be reflected on to the negative, otherwise it may prove too trying to the eyes. 2. Imperfect fixation

C. A. S. sends us two negatives that are badly fogged, except for a band of about three inches across, which corresponds with the hinge of the shutter. The plates, our correspondent says, were allowed to remain in the slides about a week after exposure. The hinges of the shutters, he says, are of some black material, coated, he surmises, with indiarubber. Fogging of the plate opposite the hinge of the shutter used to be no uncommon circumstance; but in this case it is clear that the evil arises from some emanation from the wood itself—unless, indeed, the wood allowed light to pass through it. This is quite possible if the shutter was thin and the slide was exposed to sunlight for long.

W. POTTER asks: "Is there any work published on the process of anastatic printing, or where am I likely to gain some information? I have some very old engravings, and want to reproduce by that process some copies for friends. Is it true that the matter must have been recently printed?"—The anastatic process is referred to in most works on printing, but we are not aware that any work specially devoted to the subject has been published. The process is described in *Richmond's Grammar of Photography*. With old prints considerable difficulty is experienced in getting the ink to "set off." The anastatic method has been almost, or entirely, superseded by photo-lithography and photo-zincography.

FAIRPLAY asks: "1. Is an employer entitled to pay all expenses, board, lodging, and railway fares when he sends an *employé* out of town to do a job for him, and thereby deprives him of the use of his own home? 2. Providing this has not been done, what is the best way to recover the money laid out by me."—In reply: 1. Unless there is some agreement to the contrary, we should certainly say that the employer should pay all reasonable out-of-pocket expenses. Indeed, we are surprised that any one should demur to do so. 2. The County Court, we expect, would be the only means of recovery. Perhaps some of our correspondents will kindly inform "Fairplay," and possibly others, what is the custom in such matters.

A. BROWNFIELD asks how to recover the silver from gelatine emulsions.—Several methods have been from time to time recommended, but probably the best, and at the same time most simple, is this: Liquefy the emulsion by heat, and then stir in gradually sulphuric acid in the proportion of about one pound to the gallon. The mixture should be made in a large vessel, and after the acid has been added it should be filled up with hot water. The acid destroys the viscosity of the gelatine, and the bromide of silver settles to the bottom. After decanting the supernatant liquid, and washing the bromide with one or two changes of water, it may be collected and dried ready for reducing in the furnace, or sending to the refiner.

H. D. MASON, of 46 Annerley-street, Earl-road, Liverpool, says: "Could you, or any of your readers, tell me how I can get my specimens back from Messrs. Neil & Co., Melbourne? I answered their advertisement in August 1890, and sent specimen, &c., as desired, and have never heard from them or seen the specimens since. I have applied to their agents (Gordon & Gotch, St. Bride-street). I sent stamps to pay postage back, so they have not that excuse. The specimens were chiefly 13×8, and 24×18 direct. Being the only specimens I had of those sizes, it has lost me more than one engagement."—Our correspondent's case appears an extremely hard one, and we trust that the publication of his complaint will lead to the recovery of his specimens.

THE Leytonstone Camera Club are holding their first annual exhibition and competition on Thursday, Friday, and Saturday, the 10th, 11th, and 12th of November, at the Masonic Hall, High-road, Leytonstone. There are eight classes, four members' and four open. Sixteen medals are offered for competition. Lady Brooke has consented to open the exhibition of Thursday, the 10th, at six o'clock p.m., and will in all probability be accompanied by Lord Brooke, who, by the way, are both amateur photographers. The Judges are Messrs. A. Horsley Hinton, Rev. F. C. Lambert, and Mr. E. J. Wall. The exhibition will consist of photographic productions of the leading amateur and professional photographers in the United Kingdom. Apparatus, &c., will be exhibited, together with some of the latest novelties and appliances. Lantern displays will be given twice during each evening. A fresh feature every half hour throughout each evening. High-class musical selections by the Veronese Orchestra, under the direction of Signor Constantine Baga. Entry forms and particulars of the open classes and spaces for exhibits can be had on application to the Hon. Secretary, Albert E. Bailey, Rose Bank, South-West-road, Leytonstone.

FORTHCOMING EXHIBITIONS.

October 17	.....	Camera Club.
November 10–12	.....	*Leytonstone Camera Club.
,, 15–17	.....	*Hackney Photographic Society.
,, 17–19	.....	Brixton and Clapham Camera Club.
		North Middlesex Photographic Society.
,, 24–26	.....	*Exeter Amateur Photographic Society.
		*South London Photographic Society.

* Signifies that there are open classes.

JOURNAL OF PHOTOGRAPHY.

No. 1694. Vol. XXXIX.—OCTOBER 21, 1892.

MYSTERIOUS MARKINGS ON NEGATIVES.

It is by no means an infrequent thing for some photographers to meet with strange markings, or fog on negatives, for which, experienced though they be, they cannot at once account and sometimes entirely fail to discover the origin. Several instances of this have been brought under our notice during the last two or three months. The kinds of markings under consideration may be, more or less, classified as fog, and have evidently more than one origin. Some appear only in irregular patches, while in others the plates are marked or fogged almost all over. The fog is not, however, homogeneous, like ordinary fog. Often the defects, from their appearance, if occurring on a wet-collodion plate, would at once have been put down to dirty glass, except that nothing is to be seen on the glass side of the film, and that it is more or less granular in nature.

Some negatives of the whole-plate size were recently sent us in which the markings were in patches of various sizes, some very pronounced, and others so faint as scarcely to be noticed at all. A careful examination with a lens showed that in this case the granularity took the form of the grain in some kinds of thin paper. The plates in question, it turned out, had been packed with paper between them by the makers. From this it was concluded that the plates had been packed either before they were thoroughly dry, or that the packets had been kept in the damp after they had been issued from the manufactory. There is yet another way in which the moisture might have found its way to the film.

It is no unusual thing, with plates of larger sizes than those in general use, to open a packet, take out what is required for immediate use, and repack the remainder, which may not be wanted for some time. Now, the atmosphere of the dark room usually contains a considerable amount of moisture, and, if the plates have been kept in a cooler place than this apartment, moisture will at once condense upon them, and consequently be absorbed by the film. Then, if paper, however pure, were pressed against it for perhaps some weeks, its effects would certainly become manifest. We mention this, as it is scarcely conceivable that plate-makers would send out plates unless they were perfectly dry at the time. It may be asked, if dampness be the cause, why the markings are not uniform all over the plate? It must, however, be borne in mind that, the closer the film is pressed in contact with the paper, the more pronounced will be the effect, and that much of the glass used is by no means flat.

It was no uncommon thing, at one time, for plates that had been kept in dark slides for a long period to show on development a band of fog across them corresponding with the position of the hinge of the shutter. This was obviously due to some deleterious emanations from the material of which it was composed. This may, however, be considered a thing of the past, as camera-makers now only employ such material for the hinges as they know to be inert.

Among some of the negatives lately submitted to us, that portion of the plate which had been opposite the hinge of the shutter of the slide in which it was kept has been perfect, while the whole of the other part has been fogged. In these cases it is clear that the hinge has acted as a protection, and that the evil is due to the shutter itself; and in this instance the fog appeared to be marked indistinctly with the grain of the wood. As in all wooden shutters mahogany is employed, it can scarcely be imagined that it would exhale anything that would act injuriously on the bromide film. Hence, if the evil arises from pernicious fumes, they must be sought for in the material with which the inside of the shutter is blacked. In one case, in which we had the opportunity of seeing the slide, it had been blacked with a size colour, which had become removed in places by constant dusting, leaving the naked wood exposed. Now, it is quite conceivable that, if decomposed size was used, and the slides were stored in a slightly damp place, and afterwards exposed to the heat of the sun, something might be given off that would act deleteriously on the sensitive film. The vapours of some resinous matters also have a pernicious effect on sensitive films. It was long since found that dry-collodion plates suffered by being stored in grooved deal boxes.

It must not be taken as conclusive, however, that because fogging appears only on such portions of the negatives as are opposed to the wood, and not where it is covered by the material forming the hinge of the shutter, the evil is due to exhalation, because it may arise from quite a different cause. Wood, when sufficiently thin, is transparent, it is also porous; and some of the inferior sorts of mahogany, such as is used for some cameras, particularly so. Many shutters of dark slides are not more than the eighth of an inch thick, some even less. Now, it is easy to see that a highly sensitive plate, protected only by such a shutter, would become affected if the slide were exposed for a time in strong sunlight; and this is often the case with some workers, who seem to consider that, so long as the joints are good, the slide is perfectly safe. That is a mistake.

When plates are fogged, and the fog appears on those portions that were opposite the wood of the shutter, and is absent opposite the hinge, it is more likely to be caused by light passing through the wood than from any exhalations from it. In either case we should recommend, as a preventive of the trouble, that the inside of the shutter be treated in the following manner:—First remove the old black; if size colour, with

sponge and warm water; if varnish colour, with spirit. Then mix some "vegetable black" with thinned spirit varnish—ordinary negative varnish will answer—and coat the wood with it, well working it into the pores. After the coating has become quite dry and hard it should be rubbed down with fine glass paper. This will remove some of the black from the surface, but will leave it in the pores of the wood, which will still appear as hollows. This treatment should be repeated, and a third time if necessary. The final coating must be left intact. Unless the coating were smoothed down with the glass paper, the successive layers might make the shutter too thick and uneven to work freely. The object of this treatment is to entirely fill up the pores of the wood and render it impervious to light, and, at the same time, obtain a coating of varnish that will prevent the exhalation of injurious matters.

THE STORAGE AND TREATMENT OF SENSITISED PAPERS.

It is difficult to realise that we have already nearly arrived at the end of autumn, and that we shall soon be surrounded by the innumerable troubles that arise during the colder months of the year from damp and attendant causes. It has been customary, in years past, to briefly allude to such matters as they are likely to arise, and to suggest the necessary precautions for their avoidance, but we believe that hitherto no place has been found amongst these seasonable warnings for any mention of the necessity for special winter treatment of our modern sensitised papers.

This is chiefly owing to the fact that several of the newer kinds of printing paper can scarcely yet be said to have taken a firm hold on the popular fancy, although, perhaps, in some hands they are beyond the trial stage. Platinotype has, indeed, been in use for so many years, and is employed by so large a proportion of both amateur and professional photographers, that it may be removed from the category of "new" processes, though even it, in some of its more modern forms, can hardly yet be deemed to have passed its trial. We need not, however, stay to discuss the precautions against damp necessary in working platinotype, since these form amongst the most important of the instructions issued by the manufacturers of the prepared paper for the guidance of the consumer.

The printing surfaces to which we desire more especially to allude are those having gelatine as a basis, but more especially those in which the sensitive film is composed of that substance in conjunction with a soluble salt of silver, or of other soluble and hygroscopic matter in the absence of active silver compounds. Gelatine itself, we all know, is readily acted upon by damp, which it freely absorbs if the opportunity present itself; but the danger thus arising is comparatively small, for the carelessness must, indeed, be great that would submit sensitive films, whether plates or paper, or even finished negatives, to such a degree of moisture, or to such conditions, as would cause their destruction without other aid.

Dry gelatine plates, or films on paper that are prepared for development, may be considered comparatively safe from damp if stored in an ordinarily common-sense way, though, of course, even these require the exercise of some additional care in winter. But the different "printing-out" papers which possibly contain soluble and more or less hygroscopic matters that, though inert while perfectly dry, are brought into a state of activity in the presence of moisture, must be considered from an entirely different standpoint.

Going back to the old days of albumenised paper—before the advent of the ready-sensitised article—it will be borne in mind how difficult it was to preserve the whiteness of the paper after sensitising, *especially in summer*. Here we seem, at first sight, to have the reverse conditions; but such is really not the case, for it was only the high temperature that assisted the moisture in the albumen film to cause the rapid discolouration in hot weather. The soluble and hygroscopic nitrates formed during sensitising acted, in the first place, by keeping the paper slightly damp, and then the heat completed the mischief; but, if such paper were perfectly desiccated after sensitising, and then hermetically sealed in a dry atmosphere, the discolouration was prevented for a very considerable time. In the winter months the difficulty took another form, for, though the discolouration failed to make its appearance with the same rapidity as in summer, the protracted period in the printing frame—sometimes extending to days—and the increased proportion of moisture in the atmosphere often rendered it scarcely less troublesome.

The conditions that prevail with our modern papers are not one whit more favourable to keeping, while the additional trouble is added of the decomposition of the gelatine film itself, or what is equally as bad, its softening and subsequent adhesion to anything with which it may be in contact. The coagulated albumen film had the advantage of insolubility, though even it would stick to the negative if allowed to get damp. But nowadays, with gelatine negatives and gelatine paper, the danger is immensely intensified under all circumstances where moisture has a chance of obtaining access, whether in the storeroom or in the printing frame.

As an instance of this, we some time ago purchased a packet of cut gelatine paper at a suburban dealer's, where possibly, though a good business was done, that particular article did not "move" very rapidly. At any rate, the particular batch of paper we refer to was found, upon being opened, to have been converted into a solid block by the damp of the previous winter and subsequent drying. Being a development paper, we managed to make some experimental use of it by soaking the sheets apart and redrying, a course that would have been hopeless with the ordinary run of "printing-out" paper.

What we would recommend our readers, especially the younger ones, to do is to always, if possible, open their gelatine films in a warm room, and to see that they are perfectly dry; if not, to render them so by the application of gentle heat. In the case of printing-out paper, there need not be the least difficulty in doing this, as the sensitiveness is such as to allow of the packet being opened in the ordinary sitting-room, and, if necessary, dried at the open fire. It is seldom, however, the paper would be issued from the maker's so carelessly packed as to require the latter treatment; but a very few minutes' exposure in a cold room at this period of the year will suffice to set up such conditions as not only to require drying at the fire, but to utterly ruin the paper in a very short time if that precaution be neglected.

It is this point we wish especially to emphasise, namely, that, though the paper may be in perfect condition when opened, it will in a very short time, especially in a cold room, such as most amateurs' dark rooms are, absorb sufficient moisture to set up a chemical change if the film contain soluble matter, and most likely to stick the whole into a solid block if repacked in that condition. Hence we say, First of all open the packet in a warm room and see that it is dry.

In repacking it also observe that it is still dry, and add the

additional precaution of wrapping it in tinfoil outside the first paper. This, if properly done, will prove a perfect protection against damp, and will remove all danger from that cause.

Then, again, in using the paper, before placing it in the printing frame make sure that not only the paper itself but also the negative film are perfectly free from moisture, otherwise there will be every probability of the two adhering. Even if this do not occur, the negative is pretty certain to absorb some silver from the paper, with the result that in a short time it becomes hopelessly stained.

Finally, see that the pad of the printing frame is perfectly dry. This is, at the present season, perhaps, the most important point of all, for it is really remarkable what an immense quantity of moisture is absorbed and persistently retained by a pad of felt, or even of bibulous paper. In our own practice we use felt, and, after a day's use, we find it necessary to place the pads for a considerable time in a hot oven until they cease to show signs of dampness. A pad that has lain in the printing frame for a week will, upon holding it to the fire, give off steam, as if it had just been wrung out of water.

It is scarcely necessary to point out how injurious would be the action of such a pad upon a sheet of gelatino-chloride paper placed in contact with it for a whole day, or even longer, with perhaps the chance of a stray gleam of sunshine occasionally to help draw out the moisture. In order to avoid this risk, we again recommend the resort to tinfoil as a final safeguard, a piece of it being placed between pad and print to isolate any chance damp that may be left in the former.

After printing, if an airtight case be not in use, the prints should be wrapped in tinfoil until required for toning. If this precaution were invariably observed, there would be fewer complaints of difficulty in toning.

Volcanic Photographs.—A paper, illustrated by a large number of photographs printed from process blocks, appears in a recent number of *Nature*, and shows plainly the great value of photography in recording the facts of natural phenomena. A few years ago only these photographs would have been translated by the graver's tool into very pretty woodcuts, the scientific value of which would entirely depend upon what could only be termed the engraver's interpretation of the photographic prints. These photo-engravings, large and small, are eight in number, and give a most excellent idea of the various localities at different times and conditions of the volcanic outburst.

Effect of the Ultra-violet Rays on Plant Life.—A very interesting memoir on this subject was recently presented to the Paris Academy of Sciences. The whole paper was replete with descriptions of remarkable experiments; but, as they are foreign to our science, we may merely say that it was found that the particular rays which are so specially active in photography were powerfully so on plants. While the rest of the spectrum rays had an accelerating effect on the growth and development of the plant, it was found that even at a distance of three or four yards the ultra-violet rays were prejudicial to the normal development of the plants, and to correct this glass shades were employed as interceptors.

"A Black Sheep."—Respectable Manchester photographers are to be congratulated upon the thorough *exposé*, by a local paper, of the evil doings of a photographer for some time past domiciled in that town. For years, it seems, this man's disgraceful behaviour towards his lady sitters has been notorious, and we are glad that the courageous revelations of several of them have [illegible] enabling our contemporary, *Spy*, to denounce him in such a manner as to, we hope, leave him little chance of carrying on his loathsome doings in future. His real name is said to be, not Sauvy, but Zalkind, and, instead of being French, he is a Polish Jew. His address is (or was, we trust) 22A, King-street, Manchester. The thanks of photographers throughout the country are due to *Spy* for its forcible and vigorous action. For our part, we are happy to know that Zalkind is a conspicuous exception to the general rule that photographers are a body of men as honourable and well conducted as any other in the community.

Retouching by Electricity.—"Some time ago," says *Anthony's Bulletin*, "we published a series of articles on retouching by Mr. Redmond Barrett. Taking these articles as a guide, retouching may be made simple and rapid by the use of an instrument now on exhibition in the store of our publishers. This is a small metal pencil-holder, at one end of which is a little electric motor worked by two bichromate cells. The other end carries the pencil, which is carefully sharpened with fine emery cloth. The holder is supported by a brass spring, the hand, therefore, simply serving as a guide. The cells being connected, the pencil rapidly revolves with a slight wobbling motion. The negative is rubbed over with Venice turpentine, fixed upon the desk, and all that is necessary is for the operator to guide the pencil. The instrument cannot certainly supply the worker with the requisite knowledge of anatomy, but it gives him the mechanical part, and supplies him with the means to rapidly and delicately carry out his ideas to the desired end. A cabinet bust portrait may easily be completely retouched in fifteen minutes, entailing but little fatigue to the operator."

Stills and the Excise.—That we were not in error in alluding to a widespread ignorance in the matter of excise requirements in regard to stills has further proof, if it were needed, in a letter to the editor of the *Chemical News* last week. The writer, Mr. P. Gerald Sanford, F.C.S., states that one of the results of his application for permission to purchase in quantity the old form of methylated spirit has been the visits of four Government officials, who, discovering, as was natural in a chemist's laboratory, a variety of stills and retorts, informed Mr. Sanford that he had no right to use them without a licence, which would cost 10*s.* 6*d.* Having made inquiries, and finding that few, if any, chemists paid such a licence, he refused to pay; and, after a correspondence extending over several months, he at last obtained—chiefly, he believed, through the efforts of the Secretary of the Institute of Chemistry—the necessary permission to use stills and retorts "for the purposes of his profession." This fresh evidence does but give fresh force to our suggestion that the Photographic Society of Great Britain should place themselves *en rapport*, similarly, with the Inland Revenue officials.

Wanted, a Donor of a Big Telescope.—Not content with their own existing possessions, Professor Pickering, the Director of the Observatory of Harvard College, has issued a circular inviting the wealthy to consider the opportunity offered for a donor of two hundred thousand dollars "to have his name permanently attached to a reflecting telescope, which, besides being the largest in the world, would be more favourably situated than almost any other, and would have a field of work comparatively new." The telescope in question would be placed in the station established by the Harvard College Observatory, near Arequipa in Peru, at an altitude of more than eight thousand feet. The great drawback to the use of these large instruments, and especially when photographic purposes are in view, is the difficulty of obtaining a clear and still atmosphere; but in the proposed regions the sky is nearly cloudless, and a small telescope already established there has shown that the atmosphere is also remarkably steady. The circular concludes by saying: "Even under the most favourable circumstance a startling discoveries—relating, for example, to the existence of inhabitants in the planets—are not to be expected." "It is disappointing to learn this, for a syndicate of photographers might otherwise be started to photograph them. That their [illegible] would ten[illegible] a commercial success cannot

Improvements in Photographic Lenses. — One is frequently seeing improvements in photographic lenses announced, usually through the Patent Office, and often by amateur opticians, who have but little knowledge of optics, and no cognisance of what has been done before. Here is a case in point. The specification of a patent has just been published for an improvement in the adjustment of the optical and visual foci of photographic lenses. The improvement consists in fixing to the sliding tube, in which the lenses are mounted, a pin, which works in a slot in the jacket of the mount, corresponding with the distance between the optical and chemical foci of the combination, so that, after the visual focus has been obtained, the tube is moved the distance permitted by the fixed pin and slot. Now, most persons are aware that the difference in the optical and chemical foci of under or over-corrected lenses varies according to circumstances. As the conjugate focus is increased, so is the difference between the two foci increased also—a condition not allowed for by the patentee. No opticians now turn out photographic lenses in which the two foci do not coincide. The patentee dates from the Optisch-occultisches Institute, Munich. But for the fact that the world-wide-known firm of Steinhiel are at Munich, one would, in the face of this specification, have surmised that the Bavarian capital was fully a quarter of a century behind the age in photographic optics. But the same may, perhaps, be said of some patented lenses initiated in London.

THE CAMERA CLUB EXHIBITION.

In this admirable Exhibition, held in the large room of the Club (which has been newly redecorated), there is a fine collection of photographs, excellent alike in execution and intention, in many of which, however, technical excellence has been placed on one side in favour of pictorial merit. It is a tribute to the catholicity of selective taste felt by the Club Committee that among the two hundred or more pictures hung several are the work of professional men, while many of them are duplicates of some of the most successful photographs now on view at the neighbouring Exhibition of the Photographic Society of Great Britain. The *raison-d'être* of the Camera Club Exhibition is given in the following brief preface to the catalogue:—

"The intention of the promoters of this Exhibition has been to gather together, by careful invitation and selection, the best photographic pictures of the year. Such a system, it may be said, of invitation and selection is now, for the first time in the history of photographic exhibitions, initiated in England, although Vienna and Brussels have already adopted such an obviously rational course. The invitations have been limited, and addressed to those photographers only who are known to produce artistic results. So enthusiastic has been the response, and so large the number of contributions sent in, not only from this but also from foreign countries, that the exigencies of space in our gallery have rendered the question of hanging the exhibits a somewhat embarrassing one. The space at our disposal has, of course, necessitated the exclusion of some contributions; but it is believed that such a necessity was anticipated by the exhibitors, and will meet with cheerful acquiescence. There can be little question that the title, 'Photographic Pictures of the Year,' is one which is justified by the conditions under which the Exhibition has been organized."

Although perhaps not the most excellent from a purely pictorial point of view, there is nothing in the Exhibition that surpasses in general interest a series of five photographs by Shapoor N. Bhedwar, of Bombay, depicting the consecration of a Parsee priest. The first picture shows the Zoroastrian head priest invoking a blessing upon the initiate, the expression of whose face must touch the spectator. In five progressive stages is shown the whole progress of the initiation, until the young candidate for "holy orders" is duly qualified as a priest.

Among several pictures exhibited by Baron N. de Rothschild, that of *Nach der Arbeit* (After the day's work) will be inspected with admiration. In it we have a peasant enjoying himself outside a wine house, a common enough subject, but well treated.

Although the *Caller Herrin'* of Mr. A Burchett is one of the most imposing photographs in the room, and is undoubtedly well composed, yet is the lighting not natural. Here we have a girl in the open with a basket of fish beside her. In the rather dull surroundings we have no strong light or shade apparent, and yet in the girl's face there are shadows so heavy as to suggest that the figure has been taken in a studio specially adapted to give such strong contrasts as to leave portions altogether dark. In nature one does not find such discrepancies as are there presented.

Ralph Robinson's picture, *A New Pet*, is probably the best of all his exhibits. A certain "something" has just arrived in a farm outhouse, but whether it be a calf, a foal, a kid, or something of like nature, is left to the imagination of the spectator, who is less fortunate in this respect than the three rustics who are outside and peering into the interior. A second picture by the same artist, *Making Friends*—a peasant woman engaged in getting into the good graces of a young calf—is highly meritorious, while his two other exhibits are also good.

A noticeable feature of the Exhibition is the large number of small pictures—quarter-plates and smaller. Of these we like Mr. H. M. Hastings' *Coming in with the Tide*, a delicate little yacht study; and the same exhibitor's *Tyne*, *Drawing Timber*, and *Ploughing*—these last three, however, to our fancy, would have had the finer details better rendered on a surface paper. Mr. T. J. Bright, with two placid studies of *Home to the Midday Meal* and *The Barley Harvest;* Mr. J. Guardia with *A Normandy Smithy*, Mr. H. E. Davis with *A Break in the Storm* (the cloud effects of the latter being forcibly treated), *Far from the Madding Crowd*, a solitary reaper at work, and the Hon. Sec., Mr. Davison, with ten small landscapes, are among those who shine in this particular class, most of the pictures being printed on rough sepia toned paper.

Mr. Karl Greger is represented by several pictures in his Pall Mall vein, of which we like the crisp and brightly lighted *June in the Fens;* Mr. Bergheim by several of his fine head studies, while Colonel Gale also has half-a-dozen pictures, than which nothing is better than *The Incoming Tide*, full of poetry and clever treatment of atmosphere. Lieutenant Gladstone's interior, *Mont St. Michael*, is technically excellent, and in the department of architecture, Mr. F. H. Evans also excels with his Canterbury and Gloucester series. Mr. H. P. Robinson's two pictures scarcely do him justice, the lighting of the women *Gossiping on the Beach* being rather faulty. *The Rising Lark*, a large study of two women looking upwards, is the better of the two; while his *Midsummer*, which is so placed as to elude general observation, is one of the most extraordinary landscapes in the room. Mr. Sutcliffe has a series of six not up to his usual mark. In one, the *Orthographer and his Fond Father*, a child spelling the name of a boat in the presence of a small crowd of salts, it is difficult to pitch on the man who has the honour of paternity of the phenomenon. Mr. W. L. Colls' series are admirable in technique and composition, and we like the effect of Mr. Keighley's *Gathering Clouds*. Mr. Clarence Moore's study of *Two Little Niggers*, a boy and a girl smiling together, is a clever and natural bit. Mr. Henry Stevens's *Orchids and Ferns* is quite in his usual admirable style, while the picture of his inevitable fox terriers in *Ratters*, is a capable example of animal photography. Mr. W. Crooke sends a large well-executed portrait of *Paderewski*, and Mr. Maskell three portraits of a lady, Mr. Davison, and Mr. Corbould; the one of Mr. Davison is not a good likeness. Mr. Paul Lange's *Off Aalesund* is noticeable for the cloud effects, which are vigorous and full of animated contrast.

Mr. S. Bourne's landscapes are sound, conscientious photographs, and in *The Old, Old Story* Mr. W. R. Cassels very ably depicts the fateful moment when a lover is presumably putting the question of questions to the object of his affections. Mr. Lord's *How's That*, Mr. Durrant's *Monk* studies, and Mr. Diston's *Highland Smugglers* are duplicates of those gentlemen's Pall Mall exhibits, which it is unnecessary to criticise. The lady in Mr. Lyddell Sawyer's *Study* is most naturally and elegantly posed, and Mr. D. Alexandre's *A Bivouac* and *A Modern Lesson in Anatomy* (the latter a group of students round a patient) are successful examples of subjects difficult owing to their lighting.

Tennysoniana is the theme of the exhibits of Mr. H. H. Hay Cameron and the late Mrs. Cameron, the portraits shown being in the well-known style of both artists. Other exhibitors include Richard Keene (with good architectural subjects), B. Alfieri (whose *Grey Dawn* shows a capital effect of mistiness), R. Terras, M. Auty,

E. G. Lee (whose small work is of the same quality as his lantern slides), R. Briant (the extreme fuzziness of whose *Reed Fringed Mere* is, we believe, due to the picture having been taken by means of a slit), B. Gay Wilkinson (with a beautifully defined *Millpool*), A. Horsley Hinton (whose *Reed Harvesting* has his usual "broad" treatment), P. Ennis, A. R. Dresser, G. Loppe, A. Kapteyn, Rev. F. C. Lambert, S. Conway, H. Tolley, A. J. Leeson, Captain Abney (with three excellently exposed and defined views of *Folkestone Harbour*), D. Strakosch, Lyonel Clark, F. Hollyer, E. Calland, and others.

The one thing of special interest from a semi-scientific point of view is a group of exhibits by H. Van der Weyde. It is a means of reducing the dimensions of any particular part of a photograph. For example, we all know that ladies sometimes complain of the undue dimensions given to their hands or feet by the photographer; or the head may be too large for the figure of the sitter. By the discovery of Mr. Van der Weyde this species of imaginary discrepancy may be entirely rectified. The details of his method for effecting this have not yet been made public, although it will be so eventually, as he has promised a demonstration at an early date. It is understood, however, that the interposition of a lens between the negative and the offending and too large member, has to do with the method of cure. Be the precise *modus operandi* what it may, the results thus obtainable will appeal to a large mass of the community as an improvement. Projecting parts of a figure are in the photograph sometimes considerably enlarged, and if by optical means these can be reduced in dimensions, all the better, at any rate from the art point of view.

The Exhibition, which is to be open for several weeks, is one in which the Camera Club may take legitimate pride, and is highly creditable to its organizers. The principle of only hanging invitation exhibits doubtless ensures a high average of excellence, but it has the drawback of excluding works by unknown men which might conceivably be not less worthy of such a distinction than the productions of those known to fame. In this respect the Photographic Society's and other similar Exhibitions still fill an office the utility of which is beyond question.

CONTINENTAL NOTES AND NEWS.

Restoring Faded Prints.—*Apropos* our recent articles on this subject, we observe that a Continental journal summarises the following method. Immerse the print in a solution consisting of

Saturated solution of mercuric chloride acidified with HCl	20 drops.
Distilled water	1000 c.c.

When the print has attained the necessary depth, it should be washed and dried, and may then be carried to a warmer tone in a toning bath of chloride of gold and potassium.

An Exhibition of Photographic Journals.—At Brussels, next May, an international exposition devoted to the Press, ancient and modern, is to be held in the Musée des Beaux Arts, and our Belgian contemporary, *Helios*, has been given charge of the section embracing photographic journalism, and will endeavour to gather together a complete collection of the publications devoted to photography throughout the world.

Celluloid Varnish.—The *Rundschau* mentions a fact, several times referred to in these columns, but still apparently not generally known, that celluloid dissolved in amyl acetate forms an excellent varnish for a variety of photographic purposes.

The "Bulletin Belge."—M. Hector Colard has resigned the Editorship of the *Bulletin* of the Association Belge de Photographie, which, as we have frequently had occasion to remark, forms an admirable *résumé* not only of the proceedings of this important Photographic Association, but also of the current literature of photography.

Toning with Cobalt.—M. Redares has communicated to the Société des Amateurs Photographes de Paris a note relating to the employment of cobalt for toning, in place of chloride of gold. He has tried different salts and has selected the chloride, the others only acting very slowly. The cobalt, he observes, instead of being deposited on the albumen-silver image in the metallic state, is thrown down as a brown oxide. The following is the formula he employs:—

A.—Water	1000 c.c.
Chloride of cobalt	10 gr.
B.—Water	1000 c.c.
Acetate of lime	40 gr.

100 c.c. of A and 120 c.c. of B are mixed and allowed to stand for three or four days, the solution filtered, tested with litmus paper, and, if found to be acid, a few drops of a ten per cent. solution of bicarbonate of lime are added, or, if alkaline, hydrochloric acid 1 : 10 is added, it being necessary that the bath should be neutral, otherwise it will not tone. Toning, however, takes two or three days, but fixing is accomplished as usual in hypo. The author says the results leave much to be desired, but he hopes to improve them. He also states that he toned with a similar bath in two hours, but he does not give the formula.

Potassium Chloride in the Oxalate Developer.—As a means of imparting sepia tones to bromide prints developed with ferrous oxalate, M. Hector Colard advocates the addition of chloride of potassium to the developer. The following is the formula:—

A.—Water	1000 c.c.
Oxalate of potash	330 gr.
B.—Water	1000 c.c.
Chloride of potassium	130 gr.
C.—Water	500 c.c.
Ferrous sulphate	24 c.c.
Citric acid	2 grammes.
Potassium bromide	2 „

For use twenty parts of A, five of B, and five of C. The more of B that is used the more decided will be the brown tones obtained.

AMIDOL.

THERE appears to be much interest taken at the present time in all the photographic journals in the above new developing agent. I therefore venture to offer the following description of some of my experiences with the above developer, thinking it may be of interest to many of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY who may not yet have tried the above valuable developer.

To all who have not tried it, I say do so as quickly as possible, as the time of year is now coming on when all the help it is possible to get from developers will be of the greatest service. It is one of those things that, when it has been once fairly tried, it will be always used, for all rapid, or other particular, or important work.

On Saturday, October 8 last, I had to take three cabinet negatives in a very bad light (heavy black clouds, no sun), just before it rained, between 11.30 and 12 midday. One was of a restless pony, another of the same pony in a trap containing a lady, little boy, and a dog, and the other was the lady, little boy, and a dog. A rapid rectilinear lens of 12 in. equiv. focus was used; the first had *f*-32 stop, and the two last *f*-24 stop. The exposure given was cap on and off as quickly as possible, time probably between a quarter and half a second, certainly not more than the latter. I commenced to develop with one part amidol stock solution, to three parts of water, which developed a great part of the image. I then added some crystals (several grains, number unknown) of amidol and sulphite of soda to the developing solution from time to time during the hour or thereabouts the development was taking place.

These additions, of course, increased the developing power of the solution wonderfully, and saved all the negatives. In fact, they were much better than could have been expected under the circumstances, and I firmly believe no other developer known to me would have produced anything like the amount of detail in the deepest shadows as these negatives show. *Of course, they were all more or less underexposed*, but not so much as to be useless, as, after being intensified with bichloride of mercury and ammonia, they yielded good, clear, and quick printing negatives. After developing the above negatives,

I came to the conclusion that two seconds each would have been the proper exposure to, have given with the stops employed and the light present, but the nature of subjects rendered this length of exposure impossible. Under similar conditions I shall use *f*-20 or *f*-16 stops for the future, and advise any one else to do the same.

But the foregoing experience shows the capabilities of both the developer and the plates employed. I find bromide of potassium has a very powerful effect as a restrainer with this developer, and tends to produce thin images; therefore, for normal exposures and general work, *one-eighth of a grain to each ounce of developing solution is ample*. For instantaneous or under-exposures, *no bromide* should be used. I may also add that the gentleman for whom the above were taken was very pleased with them all. All were developed with the same solution.

J. T. HACKETT.

CLOUDS.

[Manchester Amateur Photographic Society.]

To print a photograph of landscape or seascape with a purely white sky is so untrue to nature and so inartistic that nowadays it is a rarity except in the productions of the variest tyro, and we seldom see it perpetrated. That clouds are an improvement to most pictures is universally admitted, but we must not rush to the other extreme and use this power ignorantly or rashly; rather let us quietly consider how, by its means, we can convert our mere photographs into things of beauty.

SUNNING THE PRINT.

Most certainly the method of obtaining clouds on the same negative as the landscape is to be given the preference over all others; but if there is a clear blue sky you may ask, "How is this to be accomplished?" Well, unless you are using isochromatic plates your sky will most likely print white, and this, as I said before, is untrue to nature. You will have noticed the blue of the sky is darker towards the zenith and lighter when it approaches the horizon; therefore we must try and imitate this by what is technically termed "sunning the print," and is performed as follows:—Cover up the lower portion of the print, place it in the sunlight for a few seconds, shading it with a piece of cardboard, kept in movement so as to give a graduated tint on the sky—a very slight tint, indeed, is necessary, which can be gauged by keeping one corner covered by the thumb-nail.

USE OF THE LENS CAP.

Should well-marked clouds appear in the sky at the time of exposure, we should by all means try to obtain them on our negatives by giving the sky a shorter exposure than the landscape. Many ingenious mechanical means have been devised, but a simple method of taking off the cap is almost as effectual. The cap should be taken off by an upward motion and raised and lowered slowly; that is the whole procedure. There is one class of cloud subject which should invariably be taken with the landscape, or, better still, seascape. I refer to sunsets and sunrisings; the former will, perhaps, be more often attempted than the latter. There is nothing very difficult about it, although I am sorry to say it is rarely that we can secure a true impression of the scene. The principal points to be observed are to wait until the sun retires behind a suitable cloud, and to use a small proportion of pyro in the development.

HOW TO OBTAIN CLOUD NEGATIVES.

It is, however, not often that we can obtain clouds of a suitable quality on the same plate as the landscape, therefore we must have recourse to double printing, but before we do this we must get a number of cloud negatives—mind, I do not say one or two, for we should at least have over a dozen; if not, we shall most likely fall into that popular error of printing and perhaps exhibiting side by side two landscapes with the same cloud, an event that could scarcely happen in nature. It may be asked what kind of clouds we are to photograph, and I answer any kind and every kind we can get hold of—cumulus, stratified, wind-blown, mackerel sky, quiet sleepy-looking clouds; they will all come in useful at some time. Those clouds with the sun just off the angles of view are the easiest to obtain and, of course, the best illuminated. Use a plate of medium rapidity, by about *f*-22 stop and a slow shutter; use a normal developer, and, so as to get a clear, quick-printing negative, say pyro and soda.

Our friend, Mr. Shirley, advises iso. plates, which, he says, give greater detail, but personally I have found little advantage to be gained, though I may not have carried my experiments far enough.

When photographing clouds the camera should be level or nearly so, with a little of the landscape showing on the negative; it goes without saying that we must have a fairly clear view of the horizon, no poplars or factory chimneys reaching half way up the plate. To steer clear of this difficulty, some people point their cameras at an angle of say 45°, but the results are so obviously wrong that I will not stay now to point out the why and the wherefore. These people may be classed with those who gravely advise you to use your cloud negative upside down for a change.

It is necessary that every-one attempting cloud photography should be slightly inoculated with the Emersonian doctrine, for his clouds must not be quite sharp. For this reason, in a landscape we generally have the foreground and middle distance sharp, but the distance is out of focus, therefore it stands to reason that the more distant clouds should partake also of a fuzzy nature. I have some pictures by a well-known artist which show this defect very clearly. The foreground is sharp and the rest of the picture out of focus excepting the clouds, which are as sharp as the foreground.

PRINTING IN CLOUDS.

Having now got our stock of cloud negatives, we must consider next how to use them. There are several kinds of negatives to deal with, which for the purpose of this paper may be roughly divided into two classes: those giving a perfectly white sky, and those showing a decided tint. The former is the easiest to deal with, so we will take that first. Our initiatory proceeding is to take a print ready for toning in the usual way, then, choosing a suitable cloud negative, place the said print in contact in the printing frame; but, if we made no further preparation, the clouds would print on the landscape as well as the sky. To obviate this, we must take a piece of brown paper and roughly tear it to the shape of the sky-outline of the landscape, taking no notice of trees and suchlike dark objects that project into the sky. If the general objects in the distance are dark, then the clouds can overlap, but, if light, more care must be taken in the printing, and one or two thicknesses of tissue paper must project past the edge of the brown paper; this will soften the lower portion of the clouds; or another way is to keep the brown paper moving during printing.

Should the sky in our landscape negative be rather thin, we must resort to a little dodging, thus: place the back of the cloud negative we intend to use in contact with the film of the landscape, and, taking some Indian ink on the end of the finger, dab it over the high lights of the clouds, softening them off where necessary, then print as before described, but under tissue paper or in shade.

Another method is to keep the whole of the sky white by covering it while the landscape is printing, but this requires great care. It should also be remembered that on a hazy day, when we have an undefined horizon, clouds are not often seen in the lower portion of the sky, therefore should be lightly printed. Indeed, in any case do not be tempted to print the clouds too dark. Many a picture is overbalanced by this fault, and though dramatic in its effects, and so takes with the superficial observer, is ofttimes untrue to nature.

I have already mentioned that we must choose a suitable cloud negative, and much depends upon our judgment in making this choice.

LIGHTING, BALANCE, AND REFLECTIONS.

One of the first things we must consider is whether the lighting of the clouds is in the same direction as the landscape. Cloud negatives on films have here a distinct advantage, for they can be printed from either side. The next thing in importance is the artistic balancing of the picture, and in this we have in our hands a power for good or evil. Some few years ago I attempted to put before you as clearly as I could as to what was implied by a true balance of light and shade in a picture, and then went on to mention how clouds could be made to assist that important phase known as breadth in picture-making. To make this better understood, I will instance a photograph of a landscape taken on a bright summer's day. In the middle distance is a lake, and on the margin a little nearer at hand to the left is a cottage and a tree. Far away is a range of mountains clearly cut in the sunshine; but, unfortunately, the sky line is too uniform, and stretches across the landscape in a jagged line, cutting the picture almost in two, thus violating all canons of art. We now, by shading a portion of the landscape, print the mountains above the cottage somewhat darker, thus enlarging our mass of shade. We now take a cloud negative, which prints rather darker to the left than to the right, utilising it as before described, and it is now obvious that the scheme of light and shade we have been aiming for is accomplished, and will repay us for the trouble expended.

If our picture includes a sheet of still water with perfect reflections, it must be obvious that clouds wind-torn and jagged are unsuitable, but some well-rounded, quiet-looking clouds must be chosen and lightly printed for such a subject. If a portion of the sky is reflected in the water, we must then turn the cloud negative over and print also on the water, and whilst doing so covering up the sky. The film being separated by the thickness of the glass from the print just gives the right amount of fuzziness, but in carrying this out we must be careful

to have the true angle of reflection or the critics will be merciless to our faults.

It is scarcely within the scope of this paper (but might with advantage be individually considered) to do little more than mention the meteorological aspect of clouds. For our purpose the mere rudiments would be sufficient, though it would be rather trying to the temper if we were to send one of our pictures to an exhibition and call it an "Early Morning," the Judges awarding it the gold medal, and with a glow of pride and admiration we stand before it and listen to the adulation of others. Soon a rusty old savant comes along and gives a grunt of disgust, blurting out, "Why! the idiot has printed midday clouds into a morning picture," and we go home slowly and sadly, hoping that no one else has discovered the fault. But we can console ourselves with the fact that unless we have some scores of cloud negatives with notes as to the time of day and year, aspect of landscape, &c., it would be impossible to use them correctly. This being almost impracticable, we must do the best we can under the circumstances.

Different Forms of Clouds.

It might, perhaps, be advisable to mention the different forms of clouds, and for this purpose they may be classed under three heads, viz., the cumulus, the stratus, and the cirrus. The first is easily distinguished. It is often in grand rolling masses somewhat like mountains and is essentially a day cloud, forming after sunrise, and attains its maximum at noon. The word stratus indicates at once this form of cloud. It generally lies in low horizontal strata, forming in the evening and dispersing with the morning sun, therefore should only be used in morning and evening effects.

The cirrus cloud is of a fibrous nature and takes many forms; it is often called the mare's tail cloud, and is dependent on the state of the wind. These notes, perhaps, are sufficient to indicate the importance of studying the subject from a meteorological point of view.

J. W. Wade.

PHOTOGRAPHY IN SOUTH AFRICA.

Photography is decidedly overdone in South Africa; the large towns teem with studios, and prices are exceedingly low. Yet, in spite of this, it is astonishing how few amateurs there are, and how little enthusiasm exists amongst those few. This may probably be accounted for, however, by the fact that there is very little beautiful scenery here, that travelling is very expensive, and that every one is confoundedly lazy. Detective cameras are never seen, although there is a magnificent scope in that direction. The half-nude, picturesque Kaffir, the quaintly-clad Coolie, the childlike but wily Chinaman, all of whom, having a strong objection to courting death by coming under the evil eye of the camera (on the tripod), could easily be snapped off by a "detective." And the unsophisticated Dutchman can only be obtained in his picturesque state unawares; otherwise his great ambition, when photography is mentioned, is to go and wash himself, grease his hair, put on his store clothes, and stand like a Roman sentinel (with bell-bottomed unmentionables on), calm and cool, in front of a background representing a volcano in a particularly violent state of eruption; or sit in an easy attitude, with his hat on one side, and a hand spread out gracefully on each knee, in the best drawing-room of a palace, with all the studio accessories piled round. The Dutchman in his Sunday best is rather like a costermonger dressed for a bank holiday, the Dutchman at home, *i.e.*, on his waggon, with his slouch hat and long bullock-hide whip, is an interesting individual—photographically speaking. Walking by the side of his waggon, he can with the said whip pick out any one of his team—generally consisting of from sixteen to twenty oxen—which happens to be lagging. He has a name for each beast, and it is a significant fact that that one which is the most obstreperous, and consequently receives the largest number of lashes, nearly always goes under the name of "Rooi-neck"—an endearing term, signifying "Englishman."

There can be no doubt that the Dutch element is largely responsible for the very second-rate work which is turned out of most studios. The number of real artist portrait-photographers in South Africa could be counted on the fingers of one hand. The average photographer is quite content while he can keep his negatives pretty black and white, retouch up to an appalling degree, and give as much gloss on the finished photograph as possible. The following letter, which went the rounds of all the studios of a certain town, will show the tastes of the people:—

"Dear Sir,—I am coming to town shortly to have my portrait taken. I have heard that you are a good photographer. Please send with bearer a sample of the polish you use. Yours truly,—J. Van Dyke."

Take a three-quarter face, and your customer will turn the card round to look for his other ear; a three-quarter length, and he will inquire after the fate of his feet; let his face be anything but a chalky white, and he asks indignantly whether you take him for a half-cast. On the other hand, an elegant pose at a card-table, with one foot on an expensive footstool, and surroundings of flower pots and posing chairs, with a background depicting a shipwreck or a wild scene in Mashonaland, will bring joy to his heart.

Wages are fairly good. On the coast they run slightly higher than in England. In Kimberley and Johannesburg, and generally "up North," a good retoucher and operator can command from 3*l.* 10*s.* to 5*l.* per week; printers from 2*l.* 10*s.* to 3*l.* 10*s.* Expenses are in proportion. And the risk of being killed by the fine dust—which in Johannesburg carries off scores of new-comers—is also moderately high.

One year ago the lowest price in Johannesburg for one dozen cabinets was two guineas, and in most studios the charge was much higher. Now, one can be taken cabinet size—and not in the old-fashioned, common, ordinary, every-day manner—but by the "new patent, instantaneous process," for twenty shillings, and have a "beautifully finished life-size enlargement thrown in!"

To those thinking of emigrating from England to South Africa, it is most difficult to give advice. For good all-round men—a printer, operator, or retoucher, who understands only his own branch, must by all means stay at home—with a little capital, there are openings in many of the smaller towns which have no resident photographers; but it must be remembered that life out here is very different to what it is at home. The cold winter days—and very few of the houses contain fire grates—when one does not see a cloud for three or four months together, when the prints and negatives have consequently to go content with two changes of water; and when one's customers bring back the "permanent photographs," and demand an explanation as to "those yellow spots;" and the still more awful summer days, when the thermometer stands at 100° in the shade, and the airy mosquito and the vivacious flea become quite friendly, and tropical thunderstorms stroll round about twice a day; when the paper blisters as paper never blistered before, and the plates frill until one imagines that they are discontented with their condition, and have suddenly decided to become stripping films; when one learns that the coloured servants have acquired a taste for methylated spirits, and are executing a war-dance in the reception-room, or that a cyclone has carried off the roof of the studio and several of the best backgrounds—when such details as these happen, the English photographer is apt to seek out the coolest spot in the house, ponder profoundly, and whistle "Home, Sweet Home."

H. S. Ellerbeck.

ACCIDENT AND INTENTION.

[Holborn Camera Club.]

There is probably that in the experience of every picture-maker which will enable him to at once anticipate the general drift of my remarks to-night. My remarks—call it a paper if you will—shall be very brief because if they be worth anything they will then be easier remembered and because it will give us the more time to air any pet ideas which may arise, and talk over our individual good intentions (of course, none ever have any bad ones), and further discuss our accidents and failures.

The Honesty of Photographic Workers.

As my experience of photographic work and workers increases, I am bound to admit that my opinion as to their honesty (I refer to the *works*, not the workers) is not improved, and I don't think the workers often err on the side of excessive candour.

If every successful photograph were conscientiously accredited to happy chance—that is, to accident—or, on the other hand, to deliberate and premeditated intention, I wonder which list would be the longer! And, *vice versâ*, how rarely is a *bad* picture attributed to the *real* cause of its failure? How often the unreproachful instrument, the weather, the light, or "those wretched plates" bear the blame! Our own judgment, impatience, or skill, never! Oh dear, no! "Just like my luck, don't you know." Or, if it may be pointed out that the picture would be much better composed if such-and-such a feature were not quite so central, or ought to have been otherwise arranged, we get the answer, "Quite so. I know that; but, you see, I only wanted it as a memento of the place, and didn't trouble about the picture." "Didn't you? Well, then, you ought." And, oh, the deceit of it! for, if the truth were known, the camera was carefully set up, and on the ground-glass screen the subject was thought perfect and delightful, and not until the print was shown to some knowing one was the error noticed. And then there's the charming little bit of landscape, which somehow comes out all indistinct and fuzzy, no one knows why; and the critic's approval of the treatment is silently

received, as though it were due to one's artistic motive, instead of clumsiness in shaking the lens or stumbling over the camera-legs during exposure. We all know the sort of thing, from your President to the last newly elected member; an accident gives us a prize, and we unhesitatingly take the credit, and keep silence about the failures, and shirk the responsibility of them.

THE HAND CAMERA IN THE HANDS OF A TURNER OR CONSTABLE.

But all this is by way of introduction. I am not here to preach a sermon on morals, it is hardly my mission, for I fear I am so unorthodox as to believe that out of evil good may come, and hence I am seeking to show how, in the absence of good intention, or with the lack of ability to do the right thing, much good *may* arise if we only have the judgment and adroitness to turn it to account.

Now, I do not hesitate to say that if a Turner or a Constable were to arise from the grave and a hand camera placed in their hands, a brief half hour's instruction as to its use, and an open order on the nearest material dealer given them, that medals, awards, and general applause would be theirs within a few weeks. And why? Certainly not from their expert use of camera and apparatus, but from their ability (being artists) to judge when chance had given them a good result, and when a bad one, discrimination between what was worth preserving and what should be consigned to the waste heap.

In this idea of mine may be found an explanation of how some photographic workers so often score a success when, perhaps, a far more careful competitor fails. One has only to expose a sufficient number of plates to inevitably secure *some* successes, due, of course, to lucky accident. It is a question of percentage.

I remember a very well-known hand camera devotee telling me that he rarely got more than three or four good plates out of a dozen exposures, and whilst I could not help thinking that he must be as atrociously bad a photographer as he must be good customer to the plate makers, yet I could silently commend his discretion and strength of mind shown in sacrificing the bad, and only saving those children of accident, his good negatives.

MERE CHANCE.

Now, the question at issue is that if it be granted that most excellent things in photography are obtainable through mere chance—and whereas the results of chance cannot be admitted as art, what evidence is there on the other side which shall support the claims of photography as a deliberate means of artistic expression? And, further, what lesson may be drawn from the foregoing?

The occasional triumph of fortuitous circumstances in pictorial photography is undeniable, but I should not hesitate to assert that the instances of accidental success, which would not have been even greater if to the same circumstances artistic knowledge, ability, and judgment had been added, are so rare, so very rare, that they cannot be in any way accepted in the calculation. The measure of success may be so great that we are satisfied into leniency, and forbade to criticise too closely, and yet, as we study the work longer and think about it, somehow there is a something akin to soullessness which comes to the surface, and we gradually weary of it; we grow accustomed to it, and find, when the first impression has worn off, that it is wanting in that very power of endurance which is the best quality in a carefully thought out and satisfactorily produced picture. This may sound a little like dogmatism, claiming too much without definite proof. Well, I am not prepared to-night with any practical examples, but I would ask you to think this over, and apply it whenever opportunity offers. If you are content to get a moderate number of pictures which will win for you the admiration of your friends, set yourself the task of exposing a few gross of plates under fairly favourable circumstances, and you need have no fear of missing your desired end. But if you aspire higher, if your object is to attain to the best possible, then do not trust to the capriciousness of fortune and to chance; besides, what fearful disappointments will always await the photographer who depends on accident—for who has not learnt that if there be a bad negative in the batch it is sure to be that particularly favourite and much prized subject, whilst the thing we didn't care anything about turns out trumps?

OPPORTUNITY PLUS ACCIDENT.

I am convinced that opportunity *plus* accident, whilst it may furnish many successes, yet the same opportunity *plus* deliberate intention will, if the intention be the outcome of knowledge, yield a higher average of merit, even if the successes be fewer, and, moreover, we shall have failures which, because we know what we intended, and therefore know in what we have failed we should be able to turn to account and derive some useful lesson thereby.

In this direction two lines of thought suggest themselves to me which, for the sake of being definite, I will call "discrimination," or the knowing a good thing when we have it, and "application," by which I mean the faculty of turning the good to the best account.

In both of these cases a certain amount of art knowledge, instinctive or acquired, is necessary, and, important as is the *selection* of the subject, it is hardly more so than the exercise of the two above-named faculties, both of which, it may be noted, come into operation after the negative is made, and in a great measure irrespective of its qualities.

In the discrimination and recognition of the good, and in the method of making the most of it, the artistic ability of the photographer is, perhaps, first discernible, and his individuality most displayed.

At one time and another it has been my lot, I might almost say my misfortune, to have passed through my hands parcels of photographs made by the most absolute tyros; photographs taken, perhaps, during a summer holiday, of every description of subject from every conceivable situation, from the shore, from shipboard, mountain summit, or river bank, and from amongst a collection of less than ordinary merit, there now and again appears a gem which, from the rough and imperfect manner of its printing or some such character, has evidently not been appreciated by its author.

Has it not occurred within our own experience that, on looking through a batch of old prints which we had long ago thrust on one side as of little importance, we have been surprised to find some picture which, in the light of greater experience and knowledge, seems wholly satisfactory. Have we not at some time found that some friend of culture or artistic tendency has discovered, from amongst a bundle of discarded photographs, some one which he points out as a desirable and satisfactory picture. We had never noticed it before, but now that our attention is drawn thus to its merits, we are astonished that we could have overlooked it.

AN "INABILITY TO RECOGNISE THE GOOD."

How can we account for this singular inability to recognise the good? Is it because, when we first made the print and then cast it aside, we were not in a mood or frame of mind responsive to its particular sentiment? or is it because we are deficient in a knowledge of Nature, and the eye is not fully educated to perceive when a poetic aspect of Nature is transferred or reproduced in the picture? In either case we have an accidental success, and if we can decide the cause of our failing to recognise it, and then cultivate our senses and faculties accordingly, our accident will have become a source of education to us, and will enable us, not only to do, but to surpass by intention, what before was effected through chance.

This would be one phase of application, but what I had in mind was rather the preservation of an unsatisfactory print by one process in order that we may ascertain what better can be done with the subject by a different method. Let the unsatisfactory print be an object of careful study, and endeavour to draw from it an explanation of its failure. Is it the characteristic of the paper used? is it that the clouds included are not in harmony with the sentiment of the scene? is it printed too dark to suggest sunshine, or too light, or too flat, for twilight? Are the relative tones of foreground and distance incorrect, or some detail too strong or too weak, one false note in the chord producing a discord. By dodging, by shading, by cutting down, try to correct the evil, reluctant to the last to abandon it. Thus out of our failure, also an accident, we may, by deliberation and intention, come to a successful issue.

I know not if my remarks have been at all suggestive, but the recollection of certain instances in my own brief experience, when premeditated results being built upon a foundation of accidents have, in the end, proved very satisfactory, prompted the hope that these notes might not be without some indirect use. Before resuming my seat, however, I should like you to remember the following few sentences (in reality the skeleton of this paper):—Conscientious admission to oneself; submit results to experts, and endeavour to find the good in every picture; chance pictures not as enduring as premeditated ones; that, where luck has done much, knowledge would have done more; take a hint from an imperfect picture and improve upon it; do not discard a picture because at once it appears undeserving, put it by and study it another time, there may be something in it you had not suspected. A painter's parallel: the painter gets a suggestion, a hint, from an almost unintentional stroke of his brush, a passing shade, or what not; it is an accident, but he pushes it further, he builds upon it, and out of accident that was kind grows a perfect work which is not the result of blind chance, but of definite aim.

A. HORSLEY HINTON.

ABERDEEN PHOTOGRAPHIC EXHIBITION.

(In connexion with the "Scottish Homes Industries Association.")

THIS was, we believe, the first amateur photographic exhibition that has been held in Aberdeen, and, taking into consideration the short time

that they have been advertising and getting the pictures together, it turned out highly successful.

The time and place were propitious for a photographic show—for the Exhibition, of which this was a section, was opened by the Princesses Beatrice and Louise, and the streets were gay with decorations in honour of the Royal visit to the city, and visitors came to the city in thousands.

Great credit is due to Dr. McKenzie Davidson and Miss Perrie, for the very able manner by which they overcame so many difficulties in connexion with this photographic section, and on the day before the opening to be in a position to present to the press, &c., one of the most unique and charming of exhibitions, though small.

Prizes were given in amateur classes only, but in the non-competitive sections many high class and beautiful productions were sent in by professionals.

The judges were—Mr. George Mason, Glasgow; and Mr. James Ewing Crown-street, Aberdeen. The following is the list of awards:—

Class I.—Landscape—Whole Plate and over—Medal, Mr. John Milne, 4, Devanha-terrace, Aberdeen; highly commended, Mr. W. F. Wilson, Honolulu; commended, Mr. James Bowman, jun., The Square, Huntly.

Class II.—Landscape—Half Plate or under—Medal, Mrs. Greig, Cobairdy, Huntly; highly commended, Miss Emily C. Pirie, Watertonhouse, Auchmill; commended, Mr. V. C. Baird, 3, Camperdown-place, Broughty Ferry.

Class III.—Portraiture and Figure Study—Medal, Mrs. Gordon, Ellon Castle, Aberdeenshire; highly commended, Mrs. Greig, Cobairdy, Huntly; commended, Mr. George Muirhead, Mains of Haddo, Aberdeenshire.

Class IV.—Marine Clouds—Medal, Mrs. Norrie, Cross-street, Fraserburgh; highly commended, Mr. John Milne, 4, Devanha-terrace, Aberdeen; commended, Mr. James Bowman, jun., The Square, Huntly.

Class V.—Hand Camera—No awards.

Class VI.—Enlargements—C. W. Moffat, 7, Queen's-gardens.

Class VII.—Lantern Slides—Medal, Professor Finlay, Aberdeen; highly commended, Mr. Wm. F. Borthwick, 25, View-terrace, Aberdeen; commended, Mr. G. Brodie, 2, Powis-terrace, Aberdeen.

Class VIII.—Stereoscopic Slides—Medal, Mr. R. Murray, North of Scotland Bank, Dundee.

In the non-competitive classes Messrs. G. W. Wilson & Co.'s show of lantern slides and transparencies for the stereoscope was highly representative of their work, showing, as it does, the best class of work at its best.

They also showed in larger photographs—in carbon and platinotype—many specimens, and all of a high order of merit, notable amongst these, *Purple and Gold*, *Among the Breakers*, and *Sunshine and Shower*.

Messrs. Valentine, of Dundee, showed large platinum pictures of Norway scenery which attracted universal attention.

Mr. James Ewing's carbon enlargement life-sized bust of Captain Reid, is an artistically finished piece of work, and his case of 12 × 10 platinum groups show careful manipulation and artistic posing.

Messrs. Morgan make a large show, embracing, as it does, work from life-sized busts down to cabinet size, a well-arranged selection of pictures that speaks highly for the manipulative skill of the exhibitors.

Mr. McMahon, Mr. Geering, and Mr. Middleton are represented on the walls by excellent work.

The Exhibition was visited by the Princesses Beatrice and Louise, and Lady Aberdeen, who expressed themselves highly pleased with the photographic display.

Our Editorial Table.

The "Ilford Year-book" for 1893.

An elegant little pocket-book, in limp morocco covers and gilt edges The wisdom of the Britannia Works Company is shown by their giving a chief place in their *Year-book* to a diary, for which there are three days to a page. There is a judicious review of the doings of the past year by Mr. John Howson, in which he takes a rapid and comprehensive survey of most of what has transpired during these twelve months. There is also a variety of other useful information in this handsome diary.

Trade Catalogues.—Those before us include, first, that of Mr. John Harmer, Littlehampton, whose list is devoted mainly to enlargements, in carbon and otherwise. Mr. Harmer's speciality is the preparation of negatives for any of the processes by which enlargements are printed: and, secondly, that of the Thornton-Pickard Company, whose productions are now too well known to need specifying. We perceive that the firm has opened a new factory and offices at Altrincham, near Manchester.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

The fourth meeting of the delegates held on October 11, at the rooms of the Photographic Society of Great Britain, Mr. Mackie (North London Photographic Society) in the chair.—The Chairman announced the business of the evening to be the arrangement of a winter programme, but there was also upon the agenda "the appointment of a working committee." Mr. P. Everitt (London and Provincial Photographic Association) inquired if that had not been arranged at the last meeting, and the extract from the minutes was read, recording that it was deferred. After some remarks by the Chairman, Mr. Marchant (North Middlesex Photographic Society), and Mr. Golding (Holborn Camera Club), it was decided that the matter be deferred. The Assistant Secretary announced that a set of slides for circulation had been received from the Leeds Photographic Society, and sets promised from the Hull, Lancaster, and Madras Societies. The North Middlesex Society had also offered for circulation papers on *Gelatino-chloride-of-silver Paper and its Manipulation*, by Mr. J. C. S. Mummery, and *Notes on Landscape*, by Mr. Pither. Major Bruno (Southsea Photographic Society) stated that he was authorised on behalf of his Society to offer a set of slides; and the offers of slides were accepted with thanks. Mr. Everitt suggested a course of lectures on photo-mechanical processes, and, after some remarks by the Chairman, Messrs. Clifton (Photographic Club) and Marchant, it was resolved that arrangements be made for a series of technical lectures to be held, if possible, at 50, Great Russell-street, on some branch of photo-mechanical printing, and that a committee of three members be appointed to make inquiries as to the best means of carrying it out. The constitution of the Committee was then discussed, and the meeting adjourned until Friday, the 14th inst.

Adjourned meeting of delegates held at 50, Great Russell-street, Friday, October 14, Mr. W. Bedford (Photographic Society of Great Britain) in the chair.—Mr. Marchant called attention to the fact that there were no rules as to the calling of meetings of delegates, and thought the scheme ought to be put on a business footing, and suggested the appointment of a Chairman with power to call meetings and to be responsible for the agenda. It was proposed by Mr. Everitt, seconded by Mr. Marchant, and carried unanimously, that Mr. Bedford be appointed Chairman, with power to call meetings and arrange the business. The Chairman thanked the meeting for such an expression of confidence, and called on the delegates to resume the discussion left unsettled at the previous meeting, viz., the appointment of the committee to carry out the proposition as to technical lectures. Mr. Warnerke (Photographic Society of Great Britain) stated that he felt sure the parent Society would regard this proposition in a sympathetic manner, and after some remarks by the Chairman, Messrs. Everitt, Mackie, Cox (North Middlesex Photographic Society), and Clifton, it was decided that the committee consist of the Chairman (*ex-officio*), Messrs. Warnerke, Marchant, and Everitt. The Chairman referred to a circular that had been received from the International Union of Photography, the object and present position of which Mr. Warnerke explained. A question was raised as to whether an Affiliation of Societies could join such a union, and, after some remarks by the Chairman and Mr. Cox, Mr. Warnerke promised to obtain further particulars. The Chairman asked if it were possible to obtain for circulation the lantern slides sent in to the Pall Mall Exhibition, and the Assistant Secretary was instructed to see what could be done. Mr. Zachariasen (Putney Photographic Society) proposed that tickets should be printed to be issued to all members of affiliated Societies, to act as proof to the fact that the holders were members of an affiliated Society, but, after a discussion in which Messrs. Mackie, Clifton, and the Chairman joined, it was determined to obtain a stamp, and that the Secretaries of the Societies should be invited to send their ordinary members' tickets to the Assistant Secretary to be stamped. The Assistant Secretary announced that at the present moment the papers, &c., at the disposal of the Societies were as follows:—1. *Photogravure*, by Mr. A. Dawson, with examples by various firms. 2. *A Proposal for a National Photographic Record and Survey*, by Mr. W. Jerome Harrison, F.G.S., with examples by the Birmingham Photographic Society. 3. *Photography applied to the Detection of Crime*, by Dr. Paul Jeserich, illustrated by lantern slides. 4. Set of sixty Indian and Colonial lantern slides. 5. Set of seventy-one lantern slides of Yorkshire scenery by the Leeds Photographic Society. 6. Set of lantern slides by the Hull Photographic Society. 7. *Gelatino-chloride-of-silver-Paper and its Manipulation*, by Mr. J. C. S. Mummery. 8. *Notes on Landscape*, by Mr. F. L. Pither. 9. There was also an offer, of which several Societies have availed themselves, by Mr. W. E. Debenham, to demonstrate either *Transparencies by the Carbon Process* or *Collodio-bromide*, and the meeting adjourned.

PATENTS COMPLETED.

AN IMPROVED HAND CAMERA.

No. 5132. ARTHUR CHARLES SMITH and ALBERT ARTHUR SMITH, both of 258, Albert-road, Peckham.—*September* 10, 1892.

A CAMERA made according to this invention consists of an outer case of wood or metal, in one end of which is the lens, and in this case a reservoir to contain the sensitised plates is formed, consisting of an upper and a lower chamber, grooved or otherwise.

The unexposed plates are fitted with suitable sheaths, and stored vertically in the upper part of the magazine, in the space between the plane containing the focus of the lens and the front of the camera. Exposure takes place in the lower part of the camera, and the plates are dropped, one by one, through a narrow opening, into the required position.

When the top half of the magazine is full of plates, the back of the lower half is in a line with the opening or slot through which the plates fall. As the plates pass into the lower half of the magazine, the whole reservoir is caused to move backwards, and the lower chamber increases in depth while the upper chamber decreases, until all the plates are in the lower part, when the end of the upper part of the magazine nearest the front of the camera takes its place over the slot.

The plates are supported in the upper chamber by a loose floor which, when a plate is required, is slid back so as to form a narrow opening large enough for a plate to drop through into the lower part of the camera.

After the plate has fallen, the opening is closed by replacing the sliding floor, and the plate is pushed against the back of the lower chamber; the pressure is continued, and the magazine, containing the whole of the plates, recedes from the lens a distance equal to the thickness of the plate.

An efficient method of releasing the unexposed plate, pushing it against the back of the lower chamber, and giving motion to the magazine, is provided by the use of a frame which slides in the lower part of the camera. This frame is really a small trunk open at both ends, and is so placed that the light may pass through it from the lens, and act upon the sensitised plate.

The top of this frame serves as the loose floor to the upper chamber, and one end is utilised to press against the plate opposite the lens. The use of the frame renders the changing of the plates a very simple operation. By means of an attachment on the outside of the camera, the sliding frame is moved forward, and the opening is made for the plate to drop through; and by bringing the frame back to its normal position the plate is pressed into the correct position for exposing, and the magazine travels backwards.

To ensure each unexposed plate falling in front of the exposed ones, the bottom edges of the plates in the upper chamber are arranged a little below the top edges of those in the lower half of the magazine.

Instead of storing the plates vertically as described, they may be placed horizontally in the upper chamber, and the opening arranged so that the plates may swing into the vertical plane opposite the lens. In this case the sheaths containing the plates have trunnions attached to the upper corners, and these trunnions are placed in vertical grooves formed in the sides of one end of the chamber. The magazine is made to travel in a manner similar to that adopted when all the plates are disposed vertically, namely, by pushing it along the thickness of a plate at a time.

To indicate the number of the plate about to be exposed, a series of numerals is placed on the side of the magazine, and these figures can be seen through a small aperture in the side of the camera.

A shutter, which works behind the lens, is provided consisting of a piece of metal, or wood, containing the necessary aperture, fixed at right angles to the outer edge of a sector of a circular plate so centred that, by means of a rod or rods, the apertnre may be moved across the lens from side to side.

AN IMPROVED DEVELOPING TRAY OR DISH FOR PHOTOGRAPHIC PURPOSES.

No. 10,023. ANDRÉ DESBOUTIN, 70, Thurlow-hill, West Dulwich, London.—*September* 10, 1892.

THIS invention relates to the novel construction of a tray or dish for developing photographic plates or films, whereby I am enabled to dispense with the use of a special dark room.

In carrying out the said invention I provide a dish proper of *papier mâché* or other suitable material, and having a spout. This dish proper is provided with a closely fitting lid having in it a sheet of glass of a non-actinic colour—say yellow—and in the bottom of the dish proper another sheet of glass, also of non-actinic colour—say red—is inserted. Across the part of the dish having the spout I form a screen, which serves to prevent any light from entering the dish or tray through the aperture between the spout and the dish.

IMPROVED COMBINED SUBSTANCES FOR THE DEVELOPMENT OF PHOTOGRAPHIC IMAGES.

No. 14,542. JULIUS HAUFF, Feuerbach, near Stuttgart, Germany.—*September* 17, 1892.

IN completing experiments with the series of the diamido compounds of phenol and cresols, for the purpose of testing their utility in the development of photographs on halogen-gelatino-silver plates and on halogen-gelatino silver paper, it has been found that, besides the o-p-diamido-phenol, the o-p-diamido-o-cresol, and o-p-diamido-metacresol, can be used as a developing means in the same manner as the first-mentioned compound. Likewise can these two new developing substances bring out the latent image in combination with sulphites of the alkalies, or sulphite of ammonium, without the presence of free alkalies, or of carbonates of the alkalies, while, in the same manner as for diamido-phenol, their developing power exceeds that of the other developing means.

As an example, I may use—

100 cub. cent. of water.
0·5 gramme of diamido-cresol.
5 grammes of the crystallised sulphite of an alkali.

It may be remarked that, by increasing the addition of the sulphite, the reducing power is likewise increased, while this power can be decreased by the addition of acids (preferably of sulphurous acid), or of bromides or chlorides of the alkalies, so that the manner of using the developing substance for more or less exposed plates becomes obvious. Instead of neutral sulphites, acid sulphites may be used when, at the same time, all or only a portion of the free acid is neutralised by means of carbonates or bicarbonates, the recipe being thus capable of generalisation.

Having now particularly described and ascertained the nature of this invention, and in what manner the same is to be performed, I declare that what I claim is:—The employment of o-p-diamido-o-cresol and of o-p-diamido-m-cresol, in combination with soluble sulphites (such as sulphite of soda, sulphite of potash, sulphite of ammonium, sulphite of lithium), for developing photographic images on layers containing halogen silver.

IMPROVEMENTS IN APPARATUS FOR WASHING PHOTOGRAPHIC PRINTS AND NEGATIVES.

No. 19,706. HAROLD HOLCROFT, Ettingshall Foundry, Wolverhampton, Staffordshire.—*September* 17, 1892.

THIS invention has for its object improvements in apparatus for washing photographic prints and negatives, more especially for the purpose of ensuring an equal flow of water in a given direction only over the surfaces of the different prints or negatives, and ensuring a thorough constant change of the water in such manner that no portion of it passes twice along the surface of a print or negative, and of securely preventing in a convenient manner prints from coming in contact with one another or being doubled up or otherwise creased or injured by the flow.

Apparatus constructed according to this invention comprises, as an important feature, a carrier or vessel into which the prints or negatives (or prints and negatives) are placed, and through which a constant stream of water passes in one direction only, and consists, in its preferred form, primarily, of such carrier and of a rectangular water cistern or washing vessel, which may be open-topped, within which the carrier, formed as a box or shell open at each end, may be inserted. The carrier is of a width which allows of it fitting easily down between the sides of the cistern, and of a depth somewhat less than the cistern, so that when placed therein it is covered with water; and the carrier is shorter than the cistern, so that when placed therein a space may be left at each end between itself and the end of the cistern. The sides of the carrier are provided with narrow ledges, or with corrugations or other guides, to receive horizontal trays or slides upon which the prints or negatives to be washed are placed. These trays are each formed of a frame strung across in both directions for the purpose of carrying the prints or negatives, or having netting stretched across for such purpose; and it is preferred that the stringing or netting shall be of such material, or be so coated or otherwise prepared, that it will resist the action of moisture and of chemicals used in the photographic process. Each print or negative to be washed is laid upon a separate tray, and the trays are pushed endways horizontally into the carrier, each upon a pair of ledges or guides. Water is allowed to drip or run from a tap into one end of the cistern, and flows through the carrier and consequently along the surfaces of the prints or negatives therein, and out therefrom into the other end of the cistern, from whence it passes off by an overflow. It is preferred to fix a transverse wall across the top of the carrier to prevent any flow of water over the top thereof. As the flow of water through the carrier might tend to wash the prints out of the trays, a number of vertical bars of wire, sheet metal fixed edgeways to the line of flow, or other substance, pass across the outflow end of the carrier; and, to prevent any risk of the edges of the prints getting between such bars and the edges of the trays, holes, corresponding in position with the bars, are notched in the edges of the trays, and the trays are pushed up to cause the bars to be within the notches, which securely prevents the edges of the prints from getting over the edges of the trays. The bars may be set somewhat inwards from the end of the carrier, so that when the trays are pushed up in the manner described their edges will not come beyond the end thereof.

As the water flows entirely in one direction, and cannot, after having passed through the carrier, return into it but must pass away by the overflow, there is a constant and thorough change of the water passing through the carrier, no portion of it passing twice along the surface of a print or negative.

If desired, in order to more completely ensure an equal flow of water over the surface of each print or negative, the water may pass into the carrier through a division having holes pierced therethrough at heights corresponding to the spaces divided off by the ledges or other guides, and the water may pass out from the carrier through a similarly perforated division.

Instead of forming ledges or other guides to receive the trays, the trays themselves may be formed, each with turned-up edges, to carry the next tray above it.

The following are the claims:—1. Apparatus for washing photographic prints and negatives (or prints or negatives) in which trays which carry the prints and negatives (or prints or negatives) are carried in position one above another within a washing cistern (having a space at each end unoccupied by the trays) in such a manner that, with a proper depth of water (which may be controlled as desired at the outflow end), a constant supply to one end of such cistern will all, or substantially all, pass in a continuous stream once only through the portion of the cistern occupied by the trays, and thence into the other end of the cistern and away through an overflow, substantially as described. 2. In apparatus for washing photographic prints and negatives (or

prints or negatives), the combination of a carrier with a cistern, within which it is a fairly good fit widthways, in order that, with a proper depth of water in the cistern (which may be controlled as desired at the overflow end), a constant supply of water to one end thereof will all, or substantially all, pass in a continuous stream once only through the carrier into the other end of the cistern, and thence away through an overflow, substantially as described. 3. In apparatus for washing photographic prints and negatives (or prints or negatives), the combination of a horizontal carrier with a horizontal cistern provided with a suitable overflow at one end, said carrier being a fairly good fit widthways within the cistern, but shorter than it, so as to leave a space at each end between itself and the end of the cistern, and being fitted with trays (more especially for prints, but usable also for negatives) or with ledges or grooves for the negatives, or with both trays and ledges or grooves, substantially as described for the purpose set forth. 4. In apparatus for washing photographic prints and negatives (or prints or negatives) in which a number of horizontal trays are carried within a carrier, forming such trays each with portions projecting outwards from the plane thereof so that they may rest one upon another, substantially as described. 5. In apparatus for washing photographic prints, in which the prints are carried upon trays placed within a carrier, through which a stream of water is caused to flow, the employment, at the outflow end of such carrier, of bars which prevent the prints being washed out thereof, substantially as described. 6. In apparatus for washing photographic prints, in which the prints are carried upon trays placed within a carrier, through which a stream of water is caused to flow, the employment at the outflow end of such carrier of bars, which prevent the prints being washed out thereof, in combination with notches in the edges of the trays, so that when the trays are placed in position the bars are within the notches, and the edges of the prints are securely prevented from getting over between the bars and the edges of the trays, substantially as described. 7. Apparatus for washing photographic prints and negatives, substantially as described with reference to the drawings herewith, and the modified arrangements thereof, substantially as described.

Improvements relating to the Adjustment of Photographic Lenses.

No. 19842. Gerhard Hodenstock, Optisch-occultisches Institut, Munich, Germany.—*September* 17, 1892.

This invention relates to the adjustment of photographic lenses, and its purpose is to allow the lens to be adjusted for the actinic or chemical focus as well as for the visual or optical focus.

The lens tube or tube carrying the lens or combination of lenses is movable back and forth in a socket, which may be fixed when the lens does not require optical focal adjustment, or movable when the focal position varies according to the distance of the object photographed, and the ground glass or sensitive surface is not movable to and from the lens.

The movement of the lens tube in its socket aforesaid is limited by any suitable device, such as a pin and slot, the latter plain or provided with a right-angled recess or recesses, or a spring, or spring clip or clips, or detent or detents, or simply with marks, so that the lens tube may be easily shifted from its position for optical focus to that for actinic focus, or *vice versâ*, the object being to enable the lens to be adjusted to give a sharp optical definition on the receiving screen, and afterwards be shifted the exact amount to bring it into focal adjustment for a sharp actinic or chemical image.

The claim is:—A lens tube having a limited or measured free movement longitudinally equivalent to the distance between the optical and actinic foci for its adjustment in the manner described.

The Use of Aromatic Amido Compounds and of Derivatives of Phenol for the Development of Photographic Images.

No. 20,690. Julius Hauff, Feuerbach near Stuttgart, Germany.—*September* 17, 1892.

This invention has for its object the use for developing latent photographic images or views of substituted amido-phenols which have the property of dissolving readily in carbonates of the alkalies. These compounds belong to the "glycine" class, and are produced by replacing an atom of hydrogen in the group NH_2 of the amido-phenol by an acetic acid residuum. The typical formula for these compounds is:—

$$C_6H_{3-4}OH.NH.CH_2COOH.$$

These compounds are the glycines of the following amido-phenols:—

1. p-amido-phenol,
2. o-amido-m-cresol,
3. m-amido-o-cresol,
4. m-amido-(v-) m-xylenol,
5. m-amido p-xylenol,
6. o-amido-(v-) o-xylenol,
7. o-amido-(s) m-xylenol.

These compounds are used in solution with sulphites and carbonates of the alkalies for the purpose of developing latent photographic images or views.

For instance, I dissolve in one hundred c.c. of water, four and a half grammes of crystallised sulphite of soda, one and a half grammes of glycine, and two and a half grammes of potash, this compound forming a developing means particularly suitable for the development of landscapes. For portrait work and the like, the solution may be concentrated or further diluted, according to the temporary conditions as to light, plates, &c.

Having now particularly described and ascertained the nature of this invention, and in what manner the same is to be performed, I declare that what I claim is:—The use of the glycines of the following amido-phenols for the development of the photographic views or images in layers containing halogen silver:

1. p-amido-phenol,
2. o-amido-m-cresol,
3. m-amido-o-cresol,
4. m-amido-(v-) m-xylenol,
5. m-amido-p-xylenol,
6. o-amido-(v-) o-xylenol,
7. o-amido-(s-) m-xylenol.

An Improvement in Hand Cameras.

No. 14,274. Joseph Haigh, 77A, Dale-street, and 95, Lord-street, Liverpool.—*September* 24, 1892.

A method of carrying for exposure a number of sensitised photographic plates or films, by means of a frame working on an axle or pivots.

The axle is pivoted at each end, and revolves by means of a handle attached to one of the pivots, the handle being outside the camera.

Fixed to the axle at right angles to each other are four carriers, having catches top and bottom of each side for the purpose of holding plates or films to be exposed in rotation or otherwise at the will of the operator. The slides or plates when in a horizontal position are protected from light by sheets of a flexible material impervious to light, fastened to axle between each carrier.

Improvements in Portable Photographic Cameras.

No. 20,177. John Henry Skinner, East Dereham, Norfolk.—*September* 24, 1892.

This invention has for its object to produce a photographic camera wherein space is economised, and which is more easily and quickly manipulated than those hitherto in use.

According to this invention I make the camera with a fixed box front, having two wings hinged to the sides of the front, which fold down over the back when the camera is closed. These wings are provided with grooves or channels, which serve as guides, in which work pins or pegs secured to or carried by the camera end. The extremities of the said grooves or channels are recessed, and when the inner or bellows body is drawn out the pins or pegs are caused to enter these recesses. This may be effected by making the pegs or pins spring-actuated, or the wings may be hinge-bound to the sides of the camera front—that is to say, set on their hinges in such a manner as to open rather less than ninety degrees, so that when fully opened the wings are not quite parallel, but are slightly inclined towards each other. By this construction, when the inner or bellows body is drawn out, the pins or pegs on the end of the camera ride up the grooves, and entering the terminal recesses automatically secure the camera in its "opened out" position. The same result may be effected by the use of springs, catches, or their equivalents, in substitution for the pins or pegs hereinbefore referred to.

Another feature of my invention is to provide the camera with a double swing back. This is effected by providing the camera end with one central pin or peg at each side, riding in a corresponding slot in each wing, so that when the camera is opened out the end thereof turns on these pins or pegs as on axis, the axial line being always in focus, no matter in what position the camera back may be placed. When the desired position is obtained, the end of the camera can be fixed in this position by a set screw passing through one of the wings, or by equivalent means.

I economise space in the construction of my cameras by making the camera back, or double dark slide, to slide over the end of the camera, instead of sliding it into the end, as at present made. I am thu enabled to produce a camera of small size which will give as good practical resnlts as one considerably larger when made by the ordinary method of construction. In cameras of the kind known as portable photographic cameras economy of space is of great importance. In carrying out this part of my invention I secure a metal plate on the edge of each side of the double dark slide and turned inwards towards the centre to form grooves. On the edges of the camera end I cut away the wood, and secure a metal plate on each edge, so as to form a rabbet, which enters the corresponding groove in the camera back or double dark slide when the same is passed endways over the camera end.

The glass frame is, of course, made in the same manner as the double dark slide, so as to fit on to the camera end.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 24	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 24	Gloucestershire	
,, 24	Lantern Society	20, Hanover-square.
,, 24	North Middlesex	Jubilee Hall, Hornsey-road.
,, 24	Richmond	Greyhound Hotel.
,, 25	Great Britain (Technical)	50, Great Russell-st., Bloomsbury.
,, 25	Lancaster	Storey Institute, Lancaster.
,, 25	Leith Amateur	
,, 25	Warrington	Museum, Bold street, Warrington.
,, 26	Bath	Roy. Lit. & Sc. Inst., Terrace-walks.
,, 26	Barnsley	Bank Chambers, Hargreaves-street.
,, 26	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 27	Birmingham	Lecture Room, Midland Institute.
,, 27	Camera Club	Charing-cross-road, W.C.
,, 27	Hackney	206, Mare-street, Hackney.
,, 27	Halifax Photo. Club	Mechanics' Hall, Halifax.
,, 27	Hull	Royal Institution, Hull.
,, 27	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 27	Liverpool Amateur	Crescent Chambers, 3, Lord-street.
,, 27	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 27	Oldham (Annual)	The Lyceum, Union-street, Oldham.
,, 28	Cardiff	
,, 28	Holborn	
,, 28	Maidstone	"The Palace," Maidstone.
,, 28	Swansea (Annual)	Tenby Hotel, Swansea.
,, 28 ..	West London	Chiswick School of Art, Chiswick.
,, 29	Putney	High-street, Putney.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 13,—Mr. W. E. Debenham in the chair.

Mr. Ripley was elected a member.

Mr. WARNERKE, in reply to a question as to the best means of working and breaking up large bulks of emulsions, gave a sketch of the arrangement he employed, which consisted of a cylinder with a mesh (five to one inch) through which the set emulsion was forced into another vessel. Mr. Warnerke introduced to the meeting M. F. M. Richard of Paris.

THE "PHOTO-JUMELLE" FIELD OR OPERA GLASS CAMERA.

M. Richard exhibited a small camera which looked like an ordinary opera glass. Twelve plates or thirty films in sheaths were available for exposure. In focussing the image, the latter could be seen on a ground glass projecting from the side. Negatives, transparencies, and prints produced by the aid of the "Jumelle" were shown. The size of the plate or film was $2\frac{1}{4} \times 1\frac{1}{2}$. For enlarging purposes M. Richard showed an enlarging camera in which the negative was placed in a tube open to the source of light, a sheath being provided for holding the paper or plate to form the enlarged picture, the camera being of the solid body variety. An exposure of two minutes to daylight, using Eastman paper, was necessary. A special printing frame, a changing back, a frame for affixing the opera-glass camera to a stand, and other items were included in the exhibit, price of which was said to be 175 francs.

THE "FLYING" LANTERN SLIDE CARRIER.

Mr. T. E. Freshwater exhibited the "Flying" Carrier or Lantern Slide Holder. In use, having placed a slide in one end of the camera, it is pushed forward into the lantern as usual, and when the image is on the screen the second slide is inserted into the other end and pushed in the opposite direction; the first is then automatically removed, and, the second being shown on the screen, the third is inserted, and so on. A movable block which passes across the screen between the two slides acts as a dissolver. The Carrier is self-centreing, and no light can penetrate through either sides of the frame.

These rapid movements are principally effected by means of a roller inside the Carrier, which aids the slides in travelling from one side to the other.

RETOUCHING.

Mr. REDMOND BARRETT, in discoursing on this subject, said he would not discuss the worthiness or unworthiness of retouching, but he might point out that, from the earliest times, it had managed to hold a position among photographers which seemed unshaken at the present day. Overworking, however, had been introduced, and this had gradually injured the better class of work among retouching. He thought that retouching, judiciously carried out, might be considered to benefit portraiture. For example, ladies' portraits were seldom satisfactory in the natural state, consequently a little retouching was always more or less advisable; and even many gentlemen did not care to present to friends their portraits which had not received the aid of the retoucher. As regards retouching itself, he did not advocate any special touch. For himself, all he could say was, that if he saw a blemish on a negative he took it out. A great number of people preferred cross hatching, but in many negatives it was absolutely impossible to render faithfully the likeness. He had many negatives through his hands in which the likeness could not be preserved by cross hatching. If the negative were delicately lighted, cross hatching must undo the work of the operator. The retoucher, he thought, should be as free as the artist when painting a picture who forms an idea in his own mind as to the effect he wishes to produce. So in like manner the retoucher should go for effects, and get them with as small an amount of work as possible. The more lead one put on a negative the more likely to be the loss of likeness. The retoucher, however, had to work according to the ideas of the photographer. Referring to a number of untouched and touched specimens he had brought with him, Mr. Barrett said that the latter, were ordinary work such as were acceptable to the general public, and drew attention to one (a square head) in which the facilities for spoiling by the retoucher were, he thought, very great. In retouching this, he claimed to have removed defects without destroying the likeness or unnecessarily rounding the head. He appreciated thoroughly those photographers who insisted upon the limitations of retouching. Alluding to the alterations which the retoucher sometimes has to make on a negative, he said that, now and then, by cutting away portions of the waists of ladies of uncertain age, unsuccessful pictures may be made quite successful. Once a negative of a certain aged Baroness was put into his hands with strict orders to make her as youthful as possible. He did, and the lady liked the picture exceedingly. As regards alterations of the features, he said that, compared with the nose, the alteration of the jaw was very easy. He quite agreed that retouching should be limited to the bettering of the negative sent. The negative of a first-class operator having a fully developed image should only require a slight amount of retouching. The retoucher, in fact, should help the operator, and the retouching should be kept subservient to the likeness. He had often been asked to describe his method of working. The only peculiarity of his method, if he had one, was perhaps a certain amount of taste, a small amount of knowledge, and a little common sense mixed up with it. He simply took out defects with whatever stroke was necessary, always keeping the main object of the preservation of the likeness in view. He could not see how cross hatching could be accepted as the ideal of retouching, while S's all over the negative, unless produced with great precision, would not conduce to a good effect. He considered a quarter of an hour a fair time to spend over a cabinet vignette head; but one of the most successful retouchers would spend as much as three hours, which was quite needless. People made a mistake in wishing the retouched negative to look bright; to make it so one had to overwork it. The retoucher should be able to judge of the printing qualities of the negative. If a portion of a negative printed white, why should the retoucher cover it with more work, and so perhaps take away a delicate half-tone? Negatives upon which a great deal of work had been put might look ten times better than those upon which less work had been placed, but the former would come out as shadows in the prints. He advocated the treatment of negatives in a broad and open style. Scraping was simply done by cutting down—he preferred a clean cut on the film, backing it up with transparent paper and "drawing in." In this connexion he mentioned a group in which the Princess of Wales figured, and in which the head of one of the gentlemen rested against Her Royal Highness's bustle. Of course, the Prince of Wales objected to the proof, and a negative was sent to him (Mr. Barrett) to cut out the figure of the gentleman. In such a case he advocated printing one or two copies before getting the background correct; it was wise not to try and get the result at once, as they would be likely to overdo it. One of the best ways to work on the film was when one had done with pencil and colour was to varnish, and then follow up with pencil again. In the cutting of ladies' waists, they should be careful not to disturb the balance of the body. It was a pity, he thought, that operators did not as a rule retouch, it was so easy. An operator should certainly speak to the retoucher on the subject of the negative to be retouched, and thus give him the chance of making alterations which would be beneficial to the picture. For instance, in the matter of altering ladies' waists, this could be helped out by the operator in the positions of the arms. Mr. Barrett concluded by pointing out that the photographer often took credit for what was to the credit of the retoucher.

Mr. J. S. TEAPE asked if Mr. Barrett could say anything of the quality of the medium in relation to the pencil. Many retouchers used H. B.; others four or five H.'s. He supposed a different medium was used in each case?

Mr. BARRETT said he used any pencil with any medium, but he did not believe in hard pencils. Of the soft grades, No. 3 was a good and safe pencil. Hardmuth's ordinary No. 3 would be somewhere about B., and was very soft. The softer the pencil, the greater the deposit. For a four-inch head he would use a very soft pencil. He recommended a light touch and a broad point, objecting to fine points on the grounds that scratching effects resulted. With a soft pencil more continuous effects were obtained.

Mr. TEAPE said that with some of the mediums in the market he found it impossible to produce a delicate touch with H.B., the medium having such a tooth that it would not take a small quantity of lead, but received it in the form of powder, although he only used a small quantity of the medium.

Mr. BARRETT said the medium he used for many years was the Autotype Company's. Rubbing on with the finger was unsafe, as, if there was the least particle of moisture upon it, the negative was likely to be injured. He generally applied the medium with a little cotton wool.

After further discussion,

The CHAIRMAN in moving a vote of thanks to Mr. Barrett, which was carried, said that Mr. Barrett stated that retouching was generally bad. He (the Chairman) quite agreed with that. What was bettering the negative? He thought it was where they made up for faults in the photographic process, and then retouching was strictly legitimate and desirable. The difficulty of rendering the gradations as they should be in the deeper tones made the shadows of flesh too dark, and if they lightened those, and did nothing more than that, and corrected the defects of colour, they were certainly trying to do what photography would do if it was perfect. He thought, on the whole, that retouching had been a great affliction to photography, and that it was the cause of the great depression in photographic portraiture. People had got used to retouching, and that certain amount of prettiness that went with it, and were not satisfied without it. At the same time these portraits did not afford the same satisfaction that portraits did before retouching came in. It was that want of thorough feeling of satisfaction that had made people indifferent. He agreed with Mr. Barrett in denouncing cross hatching, but quite thought he (Mr. Barrett) was mistaken in saying he had no method. There was a great deal in method, and Mr. Barrett doubtless used a great deal of method himself, although he might not recognise it. There was a great deal of method in drawing and cross hatching in ordinary artistic work in black and white, crayon or pencil, or anything of the kind. Mr. Barrett's method would have been of use to the members. He was glad to hear him say that it was not necessary to spend a long time over a negative. A great deal more work was often put on a negative than was necessary, which tended to remove the likeness. They constantly saw photographs with the faces fattened out, which the retoucher said was making the sitters look younger. Was that improving the negative? If the negative were brought back to the proper point, it was an improvement; but going beyond that a mixture of the present face with the face of twenty years before was a great mistake.

AMIDOL AND HYDROQUINONE.

Mr. Archer Clarke showed several negatives, covered more or less with opaque spots, caused by commencing development with amidol, and then, to obtain density, using a hydroquinone developer, the result being, as he described it, an utter failure.

The meeting then terminated.

Holborn Camera Club.—October 14, Mr. A. J. Golding in the chair.—The SECRETARY announced that the annual supper of the Club would take place at Anderton's Hotel on Saturday, December 3, and that the annual exhibition had been fixed to be held in February next year. Mr. A. HORSLEY HINTON read a paper on *Accident and Intention* (see page 679). A discussion followed.

Aldenham Institute Camera Club.—October 11, Mr. W. Vere Mingard in the chair.—The CHAIRMAN called on Mr. H. J. Redfern to give his demonstration on *Enlarging*. Having fully explained the method of focussing, and the uses of vignetting cards, Mr. Redfern exposed two enlargements of a view of the Forth Bridge, which he subsequently developed in the presence of the members, also showing them the various dodges resorted to in development, &c.

Kensington and Bayswater Photographic Society.—October 17, Mr. R. Frogbrook presided.—It was resolved that a lantern should be purchased as soon as the funds should permit. The following donations had already been offered, namely, 1*l.* each from Messrs. Robinson, Hahm, and Brumwell. On ascertaining the total cost of lantern and accessories, Mr. Robinson kindly offered to increase his donation to the amount required, which is 9*l.* 16*s.*, thus making his generous gift amount to 7*l.* 16*s.* A hearty vote of thanks was presented to Mr. Robinson for his great kindness. Mr. G. Bursnell was elected Honorary Lanternist, and Mr. Brumwell Honorary Librarian. Upwards of eighty slides were shown by Mr. G. Bursnell in the lantern lent by Mr. Short. The members who exhibited were Messrs. Bursnell, Davidson, Frogbrook, Hahm, Hannaford, Hodd, Jones, Parratt, Seales, Sutherland, and Brumwell.

It were invidious to select for remark from so numerous a collection. The hand camera furnished the bulk of the pictures, and the snap-shots were as varied as the tones in which they were printed. The Lanternist showed some excellent results on printing-out slides of his own manufacture.

West London Photographic Society.—October 14, Annual General Meeting, the President in the chair.—The report was adopted, and the following officers elected for the ensuing year:—*President:* Mr. J. A. Hodges—*Vice-Presidents:* Messrs. W. A. Brown, C. Bilton, W. L. Colla, and C. Whiting.—*Council:* Messrs. J. J. Adam, J. D. England, R. Horton, G. Lamley, H. Selby, A. W. Scanlan, G. E. Varden, R. W. Watson, J. Wilson, C. Winter; *Hon. Librarian:* J. Wilson.—*Hon. Lanternist:* R. Horton.—*Hon. Auditors:* J. Stein and T. Turner.—*Hon. Treasurer:* W. H. Whitear.—*Hon. Secretary:* L. C. Bennett.—*Assistant Hon. Secretary:* W. S. Rogers. The terms of amalgamation of the Chiswick Camera Club with the West London Society were formally agreed to, and it was felt that the example thus set by the West London and the Chiswick Societies might be followed with advantage in those districts where two or more societies were trying to do the work which might be much better done by one strong central society. The CHAIRMAN stated, owing to new arrangements having been made at the School of Arts, it was found impossible to hold the meetings on Fridays as heretofore, and after some discussion it was arranged that Rule 7 should be altered by inserting the word "Tuesday" in place of "Friday." The change of evening will, however, not come into effect for a few weeks, and members are notified that the next four meetings will be held on the usual Fridays—October 21, Technical Social; October 28, Presidential address and lantern; November 4, Technical Social; and November 11, Mr. E. J. Wall's paper. After that date, however, the alteration will come into effect. Happening at the last moment, when it was totally unexpected, this has necessitated some alterations in the syllabus, and will lead to a slight delay in getting it printed, but every effort will be made to make the delay as short as possible.

Croydon Camera Club.—October 17, Mr. H. Maclean, F.C.S., taking as his text the Pall Mall Exhibition, gave a comprehensive exposition of his views and impressions of the chief works shown. In his introductory remarks he dwelt upon the value of an untrammelled criticism, especially when, being delivered *viva voce* at a Society meeting, any observations which were either unduly favourable or the reverse were subject to revision in the course of the evening discussion. One amongst other results of the discourse was an expression on the part of a large proportion of those present to lose no time in paying the collection a visit. Space does not allow us to give a detailed report of what proved to be an address replete with original matter. Following the above, Mr. A. E. Isaac read a paper on reduction and intensification of negatives, in the course of which he very clearly explained how, in certain cases, the application of an intensifier could be made to reduce contrasts and conversely a reducer made to increase contrast. The advantage of reduction, followed by intensification with suitable negative, was also set forth. In the discussion which followed, the President, and also Mr. Sargeant and Mr. Packham, advocated where an otherwise satisfactory negative required to be altered. As regards to printing qualities that the system of making a positive on glass, and using the modifying frames of varying exposure and development, and then obtaining a fresh negative from the transparency, should be adopted. In the course of the evening, the President presented Mr. E. H. Holland with Woodbury's *Encyclopædia* for the best print taken at a Society excursion. Mr. Packham and Mr. Hirst showed several successful enlargements, and Messrs. Sladden and Brookes a large collection of prints taken during their holidays. It was announced that a special lantern show will be held on Friday, November 4, at the Braithwaite Hall. The lecture will be for the benefit of the Club funds, and tickets may be obtained of members, price 1s. each.

Hackney Photographic Society.—October 11.—Being a Lantern Evening the usual questions were curtailed, and Mr. S. J. BECKETT proceeded to give an account of his three journeys to Norway. About 150 slides were shown, and upon each Mr. Beckett contrived to obtain some merriment. There was, perhaps, a little too much punning, one of which was a little too much for even the sedate Hackney men. "This," he said, "is a gorge outside the hotel, but is nothing to the gorge taking place inside." The lecture, however, was very much appreciated by a crowded audience, after which slides by the following members—Messrs. Carpenter (flower studies), Brown, Hudson, Grant, Dean, and Hankins—were shown.

Leytonstone Camera Club.—October 15, Mr. J. Watson Brown, M.A., in the chair.—Mr. D. G. RIDDICK delivered his lecturette upon *Hand Cameras*. He exhibited and described the "Shuttle," which was admired for its simple changing action; the "Frena," the good points of which are its simple changing action and swing back; Messrs. Watson's "Vanneck," which is fitted with a finder almost as large as the plate, and has many other improvements. He also showed Mr. Roberts' hand camera, which is provided with a swing back, and may be used upon a stand. Mr. Symmons then showed his "Eureka," and the President showed his Roberts' "Magazine" camera. Mr. Cricks, a member of the Club, brought up a new hand camera of his own invention, which met with great approval, and has advantages in respect of changing movement and shutter over any in the market. The lecturer exhibited as well numerous results of his own in this class of work, and some enlargements from hand-camera negatives. In the discussion that followed, the PRESIDENT said he preferred plates to films. He was also in favour of blind shutters. He then pointed out several advantages of a hand camera—its portability, always ready for use, being able to work without getting a crowd round, and not likely to have remarks passed and attract attention; he thought that no photographer's outfit was complete without one. Mr. WATES advocated complete simplicity of action, and was glad to see the introduction of a swing back as in the "Frena" and "Roberts," as he thought that the want of one in some of the hand cameras of the day were their great fault. Mr. T. SYMMONS followed, and considered that for snap-shots and for travelling hand cameras were all that could be desired, and strongly advocated their being as small as possible, consistent with efficiency; he also preferred a fixed focus lens, and pointed out the many advantages, but still thought that, when you once come to time exposures, there was nothing like our old friend on the tripod with which we can take our time with focussing, and have our swing back, side swing, rising front, level, &c.

Birmingham Photographic Society.—October 11, Mr. G. A. Thomason in the chair.—Mr. W. B. OSBORN read a paper on *Forgotten Processes, and Self-Help for Amateurs*. During the course of his paper, he described and illustrated some simple methods of making focussing cloths, various kind of shutters, single and double dark slides, dark-room and travelling lamps, a method of printing stereoscopic pictures, which avoids the necessity of cutting and transposing the prints before mounting, and also many other things of interest to the amateur photographer. A simple carbon printing process, invented about forty years ago by the late Mr. Pouncey, was very fully described. Several prints made by the inventor of the process and by Mr. Osborn were exhibited. A plate-washer by Messrs. Smith, of Leamington, was shown.

Brighton and Sussex Natural History and Philosophical Society (Photographic Section).—The winter session was inaugurated on Friday last, in the Librarian's Room, Royal Pavilion. The CHAIRMAN, Mr. J. P. Slingsby Roberts, delivered his opening address as follows:—"You have done me the honour of placing me in the chair of this section, and I beg to return you my sincere thanks for having elected me in my absence to so honourable and responsible a position. I am privileged to succeed Mr. Caush, who has been deservedly called to a higher sphere, and I can only wish that it were possible for me in any degree to approach him, and to fit myself, as he eminently is fit, to take the lead among you. *My* qualifications for the post of your chair are very small. As a photographer, I am an amateur of amateurs, a learner among learners; but I yield to no one in my love for the art; indeed, I cannot imagine any one who once has taken up a camera feeling anything but an increasing interest in his work. As time goes on, and he gains experience and technical knowledge, so much is opened to his mind, the pleasures of the objects around him become so greatly enhanced, that the man must be dull indeed who is not impressed by what he gains. Whether we look to the scientific or the artistic side of photography, we see its great utility as a means of education, and it truly has been called a handmaid to the sciences and arts. Our old Society has gone. Peace be to its ashes! But we must all admit that in casting in our lot with this Society we have done wisely, if for no other reason than that we are untroubled by financial considerations. The "res angusta domi" haunts us no longer. We are now inaugurating a session in our new home, and it becomes us to think how we can best justify our existence as a section of so old and well-established a Society as that of which we are now members. The Society has kindly met us with readiness, and has altered its rules for the purpose of enabling us to join it, while keeping our separate identity. How can we as photographers contribute to the general objects of the Society and promote its good work? After some thought and a great deal of hesitation I have decided to recommend to the members of this section that it should undertake a photographic survey of the county of Sussex. That certain districts should be allotted to such members as express themselves willing to join in the work, the objects of which would be to illustrate the beauties of the natural and artistic features of the county, and by such records to preserve memorials of those objects upon which time—the consumer of thing—is fast laying his hands on. Similar undertakings have been carried out in other counties by the local photographic societies, and even in Sussex, less rich though it is in beauties, historical and otherwise, the work would commend itself to us; but when we know what she has been in the past, how her history is, from the time of the Conquest, inseparably interwoven with that of the nation at large, and what precious relics illustrating that history are still ours—ours perhaps but for a season, for in these utilitarian days many agencies are at work before which the past, with all its traditions, must give way—when we think what Sussex is now, and realise how priceless to us would have been such a record had our ancestors been able to form it, we surely cannot hesitate to make this our first work, and attempt to do our duty to those who come after us. If this idea is approved and well carried out, I venture to think that the Photographic Section of the Brighton and Sussex Natural History and Philosophical Society will have done something by which it may be remembered. I have reason to believe that the President-elect of the Society will concur in my views as to this, and perhaps some one who agrees with me will move a resolution approving the scheme and referring the matter to the Committee to settle the details. In the meantime I can do no harm in saying that any suggestions from the members of the Society, or of this section, as well as any offer of working help, will be gratefully received. Before I sit down I should like to call your attention to the Prize Fund. This is one which concerns this section alone, and, as we have no funds, we must depend on voluntary subscriptions. It is felt by the Committee that prizes of some sort are necessary to encourage rivalry, and the fund has, as you will see by the lists before you, been started. It is hoped that the requisite amount, which is not large, will be soon got together, and perhaps, through casting their bread upon the waters, will find it again after a short time in the shape of medals or certificates, either of which, I can testify, is worth possessing, not only for the sake of the honour, but as a work of art, they having been beautifully designed by Mr. Hunter Graham, an artist whom we have the good fortune to number among us. Allow me, in conclusion, to thank you again for intrusting me with the duties of this chair—duties which are the more responsible as, by a recent vote of this society, Chairmen of Committees are members of the General Council of the Society." This was followed by a paper, by Mr. E. J. BEDFORD, on *Perspective as Applied to Photography, the Use and Abuse of Wide-angle Lenses*. The lecture was profusely illustrated by carefully prepared diagrams, and handled in a very able and practical manner. A discussion followed. The Committee recommend that a competition for hand-camera work should be instituted, which was carried.

Derby Photographic Society.—October 11.—The first business was the election of officers for 1893, which resulted as follows:—*President:* Captain W. de W. Abney, R.E., F.R.S., &c.—*Vice-President:* Mr. Richard Keene.—*Committee:* Messrs. G. Walker, T. Scotton, C. B. Keene, A. H. Bennett, R. Woods, C. Bourdin.—*Treasurer:* Mr. A. B. Hamilton.—*Hon. Secretary:* Mr. T. A. Scotton, 9, Church-street, Derby. It was decided to hold an

exhibition of members' work in January, 1893, and the medals which will be awarded in the outdoor-meeting competition to be presented on this occasion. An exhibition of lantern slides made by the members was also held, about 120 pictures being passed through the lantern. Votes of thanks to Mr. Keene for presiding, and to Mr. A. Scotton for managing the lantern, were passed, this concluding a very interesting evening.

Minneapolis Camera Club.—This Club was organized last May, and was incorporated June 4 following. A committee was put at work at once, looking up suitable rooms. They succeeded in securing very satisfactory quarters at No. 26, South Sixth-street, between Nicollet and Hennopin-avenues, the two principal streets in the city. The location is a convenient one; one street car line passes the door, and nearly all the others within half a block, and only half a block from the business centre—Nicollet-avenue. The Club was fortunate in finding such a location, and also fortunate in the fact that the rooms were formerly occupied by a professional photographer as a gallery, and are well adapted for the purposes of a Camera Club. The first, as you enter, is the reception-room and library, 12×14 feet in size, and is neatly furnished in antique oak. A large Smyrna rug covers the floor, which adds a bit of comfort to the general homelike air of the room. Over in one corner stands a book-case, well filled with photographic literature. This is one of the instructive as well as ornamental features of the room. A reading table, covered with all the current photographic magazines, stands in the centre of the room. The next room is used as a general work-room, and contains twenty lockers. It is here that the members of the Club keep their apparatus and various other pieces of personal property, and it is here where all work of a "tinkering" nature is done. Passing from the work-room, through double doors, one enters the large and commodious dark room, which is fitted with three sinks and all the usual paraphernalia of a modern developing-room. There is a gas stove for heating water and for platinotype developing. Incandescent electric light is used exclusively in this room, as well as in all the others, for lighting. Orange-coloured paper is used as a medium for obtaining non-actinic light. The lamps are ingenious contrivances, whereby any number of thicknesses of paper or glass may be used and changed at will, or the whole arrangement may be detached instantly, leaving the ordinary white light. There is space left in this room for three more sinks, should it be found necessary to put them in. Going back through the finishing-room, one enters the studio and exhibition-room. It is 15×36 feet in size, making it sufficiently large for all purposes for which it is intended. It can also be used as a hall for public exhibitions, as has already been done, seating 100 persons. In this room is one of the best skylights in the city. The top light is 12×12 feet in size, and is at an angle of about 45°. The side light is 5×12 feet, and reaches within two feet of the floor. It is well provided with shades and curtains, so any desired effect in lighting may be produced. The room is well equipped with backgrounds and accessories, and the Club is now negotiating for the purchase of a portrait camera and lens, which will be added in a short time. One background is 10×10 feet in size, and has a lantern screen on the back, so that by simply turning the frame around, and placing the other backgrounds behind it, and out of the way, the room is ready for a lantern entertainment. The Club is fortunate in having the use of a 200 dollar dissolving stereopticon, the property of the President, which is always available for such entertainments. One more room is an extension of the dark room, and can be reached from the studio or from the finishing-room. It is a convenient place to change plates while using the studio, but it has been reserved for the enlarging apparatus, which will soon be in place. The rooms have all been newly decorated, the floors polished, and the woodwork refinished. The printing-room is on the next floor above, and has a capacity of about fifty frames. It is well provided with sinks and washing tanks. This gives the members all of the advantages of a well-equipped photographic studio, in addition to the many social features of the Club. The regular meetings of the Club are held on the second Wednesday of each month, and arrangements have been made for a series of lectures on various subjects of interest to photographers, which will extend nearly through the winter. There will also be a series of special meetings on the fourth Wednesday of each month, when some member will be selected to provide such entertainment as he is fitted for. The membership of the Club is divided into three classes—active, associate, and honorary. It is necessary that active members should be residents of Minneapolis, and over eighteen years of age. Associate members include ladies, non-residents, and stock dealers. The active membership is limited to fifty, the associate to twenty-five, and the honorary to ten. The initiation fee for active members is ten dollars, and the annual dues are also ten dollars. The associate members are required to pay one-half the above amounts. The Club extends to the members of other photographic clubs throughout the country invitation to make use of the rooms and all their privileges while in the city. A reception was tendered by the Club, Wednesday evening, September 14, to its many friends, in honour of the opening of the new rooms. The invitations were generously responded to, and a large number were present, when Ralph D. Cleveland gave an informal talk on *Pictorial Effect in Photography*, illustrated by about one hundred lantern slides. An admirable feature of the entertainment was the work of the members exhibited about the rooms. The walls of the rooms are hung with framed pictures taken by the members, all of which adds to the artistic effect. The membership is at present twenty-four active, and two associate, with an average of two new applicants each week. If the increase continues at this rate, it will not be long ere the limit to membership is reached. The officers are:—*President:* Mr. William M. Tenney.—*Vice-President:* Mr. William Channing Whitney.—*Treasurer:* Mr. W. C. Porter.—*Secretary:* Mr. A. L. Eidemiller. All the business of the Club is transacted by a board of ten directors, which include the above officers, and the following members:—Messrs. William T. Rolph, J. M. Greaves, E. H. Houlton, F. E. Haynes, Russell M. Bennett, Wayland B. Augir.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—October 27, Members' Open Night. November 3, *Rapidities of Various Printing Processes* (continuation), Mr. B. Foulkes-Winks.

Correspondence.

GELATINE PAPERS.

To the EDITOR.

SIR,—May we point out one or two errors into which "Cosmos" has fallen in your issue of yesterday?

First, we would say, that the "blue nuance" is not inherent to gelatine papers, but is due, in all cases, to the method of toning employed.

With the Ilford formula for P.O.P. this *nuance* is absolutely wanting, and evenness of tone is quite as readily obtainable as with albumenised paper, without any previous experience.

In proof of this we forward you a batch of fifty prints received this morning from a professional photographer; these are not picked prints, but the result of every-day printing-room work, such as we could obtain from fifty or a hundred professional studios to-day. We challenge the most experienced professional printer on albumen to equal these prints under similar conditions.

We would also point out that "Cosmos" is wrong in saying that all the paper which is used for coating comes from one source. We know at least five firms who supply such raw material, and have tried all their productions.

Possibly a little more experience of his subject will show "Cosmos" how much he is in error.—I am, yours, &c.,

For the Britannia Works Company, Limited,
JOHN HOWSON.

Ilford, October 15, 1892.

[The large collection of prints submitted entirely bear out Mr. Howson's statement relative to their absolute uniformity of tone.—ED.]

ENLARGING SMALL PICTURES FOR STEREOSCOPIC EFFECT.

To the EDITOR.

SIR,—An idea has occurred to me of having a quarter or 5×4 camera fitted, preferably with a roll holder and a blind shutter working close to the film, for use for single or stereoscopic pictures. The stereoscopic pictures would, I presume, be too small for viewing through the stereoscope; but could I not enlarge them either on paper or transparency plate, and by so doing transpose them at one operation to the proper position for the stereoscope without any intermediate copying?

I should use the camera for both hand and stand exposures, and by working with lenses at *f*-4, be able, I apprehend, to take snap shots in bright weather, without the brilliant glaring sunlight so necessary for most hand cameras. A horizontal level would be used for stereo snapshots.

Would you be so kind as to say whether in the above idea there is anything optically, or mechanically wrong or impossible, and if not, could you suggest any improvement for the purpose I have in view, bearing in mind that I expressly wish for a small camera. At the same time, kindly say if you consider there is really any ground for the statement frequently made, that enlargements from transparent films are coarse and grainy compared with those from glass negatives. With thanks in anticipation, I am, yours &c.,

INTENSITY.

October 15, 1892.

[No amount of subsequent enlargement of the small pictures would give the necessary stereoscopic effect. A stereoscopic angle, the base of which is less than the distance of the eyes apart, is unsatisfactory. Enlargements made from transparent films are not necessarily coarser than those made from glass negatives.—ED.]

AN AMALGAMATION OF SOCIETIES.

To the EDITOR.

SIR,—Will you kindly note that the amalgamation of the Chiswick Camera Club with the West London Photographic Society, has been accomplished, and that the official title of the Society, for the space of one year from the present time, will be "The West London Photographic Society, with which is amalgamated the Chiswick Camera Club."—We are, yours, &c.,

LIONEL CHARLES BENNETT,
Hon. Sec. West London Photographic Society.
H. HARDING MILLER,
Hon. Sec. Chiswick Camera Club.

October 15, 1892.

"COOL WATERS."

To the EDITOR.

SIR,—Messrs. Morgan & Co. may dismiss their anxiety; I do not want their money. I have attained my object, which was to make it known that they had no right whatever to be described as producers of the photograph from which the reproduction in the *Illustrated News* was taken, to which reproduction their name was appended.—I am, yours, &c.,

HENRY WHITFIELD,

October 17, 1892.

To the EDITOR.

SIR,—I have long since ceased to take any active interest in photography, and it was only by what I may term a most extraordinary incident that my attention was drawn to the correspondence respecting the picture *Cool Waters*, and, as my name has been used in connexion with the said picture, perhaps you will kindly allow me a hearing in the matter, *i.e.*, if you and your readers are not already tired of the subject.

Memory is proverbially treacherous, but I think I can safely say that the ticket in question does *not* bear the description which Messrs. Morgan say it does. What it does say, and what it was carefully and deliberately meant to say, was: *Cool Waters.* Photographed from Nature. Enlarged by J. Vaughan. The omission of the conjunction "and" makes all the difference in the meaning intended to be conveyed, so that Mr. Whitfield's contention that the ticket only "told half the truth" at once falls to the ground.

But, further, Mr. Whitfield says that "the enlargement merely was Mr. Vaughan's part." The *real* history of the picture in question is as follows:—Mr. Whitfield was fortunate enough to secure a negative of the cattle in the water; a print or two was struck off from it, and the negative stored away. One day, in looking through the negatives, I came upon this one, and I thought it would make a good picture if enlarged. I therefore took it in hand, *selected a suitable* cloud negative to go with it, and then made a combination carbon transparency. Only those who have had to make such combined transparencies can realise the care and difficulties involved; at least a dozen were made before one at all satisfactory was secured. It was then put in the enlarging camera and enlarged *so as to leave out one of the animals*, which, being somewhat separated from the rest, spoilt the balance of the composition. My partner, Mr. Whitfield, was then consulted, and he approved, the enlarged negative was then made, and copies printed, and *I* afterwards dubbed the picture *Cool Waters.*

By this you will see that not only was the enlargement my work, but also the combination transparency from which it was made, and also the title was my selection. I therefore leave it with you and your readers to judge who was most responsible for any merit the picture may have; but does not this reduce the previous correspondence to the *reductio ad absurdum?*

Apologising for troubling you with so long a letter on such a personal subject.—I am, yours, &c., JOHN VAUGHAN.

Edinburgh, October 15, 1892.

[This correspondence here terminates.—ED.]

THE LEYTONSTONE EXHIBITION.

To the EDITOR.

SIR,—Will you please give notice to remind your readers that October 25 is the last day for receiving entry forms in our forthcoming Exhibition.—I am, yours, &c., A. E. BAILEY.

Rose Bank, South-west-road, Leytonstone, October 17, 1892.

THE SOLUBILITY OF SULPHATE OF SODA.

To the EDITOR.

SIR,—My attention has been called to a paragraph in last week's BRITISH JOURNAL OF PHOTOGRAPHY, in which "Cosmos" criticises a statement which I made *re* oxidised sulphite of soda, at a meeting of the Hackney Photographic Society, held September 6, and states that sodium sulphate is about twice as soluble as the sulphite.

He is correct if he refers to the solubility of ordinary crystallised sodium sulphate in cold or warm water, but four forms are known—(1) anhydrous; (2) with 1 molecule of water of crystallisation; (3) with seven molecules of water; (4) with 10 molecules; the last is the ordinary commercial form, but I referred to the first (anhydrous) form, and its resistance to the action of hot water. According to Foureroy, sodium sulphite dissolves readily in an equal weight of water at the boiling temperature, whereas anhydrous sodium sulphate requires about two and a half times its weight of water at the same temperature (Gay Lussac), and then dissolves very slowly.

Sodium sulphate is more soluble in water at 33° C. than at any other temperature. When a solution, saturated at this temperature, is cooled, it deposits ordinary crystallised sodium sulphate (providing a nucleus is present); but when the temperature is raised, it deposits the monhydrated sulphate $Na_2SO_4H_2O$. If ordinary crystallised sodium sulphate be boiled with water, a portion of it soon becomes converted into white opaque masses, which are very difficult to dissolve. The member had used hot water (boiling, if I remember rightly); from his remarks, I concluded that the substance consisted chiefly of the sulphate, and, as sodium sulphate is completely efflorescent, there was probably a considerable quantity of the less hydrated forms; I therefore thought that the residue, as well as the failure to prevent stain, would probably be "due to its having been oxidised to sulphate."

Reports of meetings of societies are (generally) necessarily brief, and full explanations cannot well be given. "Cosmos" would do well to remember that many substances exist in more than one form, and that different forms often have different properties, also that the temperature often influences the result.—I am, yours, &c., W. H. SODEAU.

October 18, 1892.

FREE LANTERN ENTERTAINMENTS.

To the EDITOR.

SIR,—A society is being formed for the purpose of giving free lantern entertainments at the various London hospitals and charities. The first meeting is fixed for Thursday next, the 27th inst., at the above address, in room XL, for 8 p.m. sharp, when all gentlemen wishing to help in this effort to brighten the lives of our less fortunate fellow-creatures are asked to attend the meeting.

All who wish to join this society and cannot attend are desired to communicate with the undersigned.—We are, yours, &c.,

Y. M. C. A., 182, *Aldersgate-street, E.C.* B. FOULKES WINKS, F. SIMMONS, } *Secretaries.*

"NEGATIVES FROM NEGATIVES."

To the EDITOR.

SIR,—My attention has been directed to a communication on the subject of reversal, or "Negatives from Negatives," by E. Frewing, in last week's issue.

The following statement is the part which most interests me. He says: "If you begin with a short exposure, you obtain a transparency; continue the exposure, you get a negative; further expose, and you again find you have a positive; and these changes undoubtedly occur many times over." This statement does not in the least agree with the result of my experiments in the subject. I have not been able to obtain a positive after the first reversal. My experiments were carried out in the following way:—An opaque material was used to cover half-plate; ten diamond-shaped openings of half-inch side were cut in this screen, and put in front of an Ilford ordinary. The exposures were 1, 2, 4, 8, and 16 seconds to clear sky, and so on until 8 hours 59 minutes and four seconds were reached. They were developed with hydroquinone. I may just say that at the end of each exposure a piece of opaque material was gummed over the opening.

Now, all these diamond shapes are clear, the first one not quite so clear as the rest; but even this is as clear as the majority of negatives. Not being satisfied with this, I went further. With a plate behind opaque screen, I exposed openings from one hour to eight hours to the strongest sunlight in August, developed with hydroquinone, and still there is no change in the exposed openings. But, judging from the halos which appear round some of the openings, I think it is plain that even the protected part of the plate is becoming reversed by the spreading or scattering of the light. It is this scattered light which forms the image in obtaining a negative from a negative. To guard against any mistake, I have made the experiment described by Mr. E. Frewing, with result as I expected—no positive after the first reversal.—I am, yours, &c., J. S. TEAPE.

54, *Pearson-street, Kingsland-road, October* 18, 1892.

LANTERN POLARISCOPE AND ELECTRIC LIGHT.

To the EDITOR.

SIR,—In reply to Sir David Salomon's letter in last week's JOURNAL, I am very glad to learn such satisfactory results can be obtained with the polarising apparatus having small prisms, and that lecturers who have access to electric-arc lanterns will be able to avail themselves of moderate-priced polariscopes for projection work.

This subject is of so much interest that I propose later to refer to it in a separate article, also to the use of the incandescent electric light in ordinary optical lanterns. My own experience at first was, like Sir David's, somewhat adverse to the "focus" lamp; but, with modified apparatus, it answers capitally, and performs useful work in the drawing-room for projecting photographs, &c., and for lectures to small classes, without injuring the slides.—I am, yours, &c., G. R. BAKER.

London, October 18, 1892.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical Meeting, October 25 Subject: *Architectural Photography.* This meeting will be held at the Society's rooms, 50, Great Russell-street, *and not at the Gallery*, as previously announced.

AT the sixteenth annual Stanley Show of bicycles, tricycles, their accessories, cycle-making machinery and tools, and photographic apparatus by the leading houses in the trade, to be held at the Royal Agricultural Hall, Islington, N., from November 18th to 26 inclusive, there will be a photographic section. Fifteen medals (five gold) are offered for competition. The Judges are:—Mr. J. Traill Taylor, Mr. H. Sturmey, Mr. Andrew Pringle; and the Hon. Secretary is Mr. Herbert Smith, 29, Finsbury-pavement, E.C., of whom entry forms and all further particulars may be obtained. The following are the classes:—A. Instantaneous Cycling Subjects, sets of four. B. Instantaneous General, sets of four. C. Landscape or Seascape, with or without figures. D. Lantern Slides, sets of six. E. Pictures by Platinotype Process, any subject. Of these classes A and E are open; while B, C, and D, are open to amateurs only. In C and E, the medals being for single pictures, they should, if possible, be framed separately.

Answers to Correspondents.

PHOTOGRAPH REGISTERED:
John Anderson, Dalry, Ayrshire.—*Photograph of the Rev. J. L. Fyfe.*

W. H. FRYER.—No work is published on the subject.

R. N.—Employ thick starch paste. There is nothing better.

C. G. B.—The cause of the spots on the prints is being investigated.

F. BROMHEAD requires the address of Messrs. Mason & Payne, the makers of the Crystal Palace lantern screen.

W. W. N.—Supposing the wide angle and the rapid doublet be worked with the same ratio of aperture to their focal length, there will be no difference in their rapidity.

A. B. inquires: "Will some one kindly instruct me in the best way of enamelling photographs with collodion? I have tried squeegeeing them on glass, but find it is not a permanent enamel. Is the spotting done before or after enamelling?"

J. D. TRINGROE (Whittlesea).—By copying and selling the pictures you render yourself liable to prosecution. We gave you this answer on September 23. Why do you not read your JOURNAL? We do not undertake to answer letters through the post.

R. WADE.—A suitable gas engine for generating electric light for studio work would be a six or eight-horse power "Otto." It would be more economical to obtain the current from some local installation if possible. Surely the electric light is in your town.

A. WALTERS asks if there is any way by which sensitised paper that has become discoloured by keeping can be utilised?—The only way we are aware of is to add it to the residues, and thus obtain the silver from it. There is no way of using it for printing.

WILTSHIRE.—If the engraving is copyright, and there is very little question in the matter, it will be illegal to copy any particular figure in it for any purpose whatever. It matters not that the artist and engraver both reside abroad if the copyright is registered here.

INQUIRER (Liverpool).—The only suggestion we can make is to advertise for employment. You might also apply to the Photographers' Benevolent Association. The Secretary might have a vacancy on the register. Unfortunately, there are a large number of assistants out of employment just now.

A. W. J.—There will be no difficulty in enlarging on bromide paper from quarter-plates in a lantern with a four-wick lamp. Enlargements are made in this way by many amateurs during the winter evenings. One or two trials on small pieces of paper will give an idea of the exposure required. Experience in this direction is quickly ganied.

E. H. D.—It is impossible to say the cost of sensitising a quire of paper without knowing the amount of chloride with which it is salted, and the time it is floated on the silver bath. The only way by which the cost can be arrived at with accuracy is to prepare a bath of a given strength, sensitise a quire of paper upon it, then assay what bath is left, and see how much silver has been consumed.

QUIZ says: "How do you think, with regard to photographs taken while you wait, the ordinary dry plate would do developed up thin, and after washing immersed in a solution of chloride of mercury, which brings it up very near the glass positive in resemblance. As to its permanency I cannot speak?"—The idea might answer if the picture were backed up with a black substance; such an image would be permanent enough as things go.

S. W. says: "While intensifying a negative with mercury and ammonia I have unfortunately, through careless washing, stained it badly. If my memory serves me right, there was a bath of some kind mentioned in one of the ALMANACS for removing such stains, but I have looked through eight of the ALMANACS without coming across it. Can you help me?"—Probably by converting the image into pure silver chloride and dissolving off in hypo the stain will vanish. You will then need to reintensify the image.

PUZZLED writes: "Enclosed you will find a photograph, which you will notice has a yellow cast in one corner; it will spread all over the print in time. It has been finished about six months. I have been puzzled a great deal lately with my prints turning out like this. Of course, only some of a batch turn out like this. I would be glad of your advice as to the cause."—The yellowness complained of arises from the print being imperfectly fixed—time in the bath too short, bath too weak, or prints allowed to stick together while in the solution.

S. WILKINS says he has been making experiments in carbon printing by the single transfer method, and, intending to try the double, obtained some flexible support for the purpose. Being told to treat that like the single transfer paper, he finds, upon putting it in the cold water, that the surface behaves just as if it were greasy. He asks if this is as it should be?—Yes, the prepared surface has been treated with wax to prevent permanent adhesion of the picture. As our correspondent appears to require a little elementary instruction, we advise him to obtain a cheap work on the subject.

BHOOLIGHAN says: "I should esteem it a favour if you would state, in the 'Answers to Correspondents' column of THE BRITISH JOURNAL OF PHOTOGRAPHY, whether silver prints toned but very slightly (just enough to make them of a red brown tint) are likely to fade or otherwise deteriorate more quickly than if the toning process is carried farther towards the purple stage. I like the red brown colour best, but have doubts about the permanence of such prints which I should like resolved one way or the other."—Theoretically, the more the image is composed of gold the more permanent it should prove.

THE LANTERN SOCIETY.—Next Meeting, October 24. A new form of lantern in aluminium shown and worked.

PHOTOGRAPHIC CLUB.—October 26, Smoking Concert. November 2, Annual General Meeting (members only).

HACKNEY PHOTOGRAPHIC SOCIETY.—The last day for receiving entries for the Competition will be the 29th of the present month. Forms, &c., will be sent on application to W. Fenton Jones, Hon. Secretary. Among the apparatus section will be the following:—Marion's, Paget, Park, Platinotype, Wray, Photography, Platt, Wormald, Watson, Doublet, Grant & Cocks (electric lighting for dark rooms). Messrs. Elliott & Son will show their big 7×5 feet picture.

THE Tunbridge Wells Amateur Photographic Association holds its sixth annual Exhibition at the Great Hall, Tunbridge Wells, on Wednesday, Thursday, and Friday, November 23, 24, and 25, 1892. The following are the classes, for members only:—1. Architecture, exterior or interior. 2. Interiors, other than architectural. 3. Landscape and Seascape. 4. Genre. 5. Lantern Slides, best series of six, any subject. 6. Transparencies and Stereoscopic. 7. Scientific, or any subject not included in the above. 8. Four prints from negatives taken with a hand camera. 9. Four Lantern Slides. The following are open to members of any photographic society in Kent and Sussex, best set of four prints:—10. Figure Studies. 11. Landscape, Seascape and Architecture. And the open classes are:—12. Landscape or Seascape, amateurs. 13. Genre, amateurs. 14. Lantern Slides, best series of six, amateurs. 15. Architecture, exterior or interior, amateurs. 16. Landscape or Seascape, professional. 17. Genre, professional. 18. Lantern Slides, best series of six, professional. 19. Portraits, professional. 20. Enlargements. One silver medal will be given for the best exhibit of apparatus. A fee of 10s. 6d. will be charged for a space of twenty square feet. There will be lantern, musical, and other entertainments each evening. Further particulars may be obtained of Mr. Joseph Chamberlain, Hon. Secretary, 14, Calverley Park-gardens, Tunbridge Wells.

LANTERN PLATE VARIATIONS.—We have not for some time seen a small collection of lantern transparencies of more educational value than some shown us by Messrs. Mawson & Swan, Soho-square. They exhibit very plainly the difference of result obtained by slight modifications of the developer. The plates were all taken from the same packet of the "Mawson Lantern Plate," and were printed in the camera, being reduced from a 12×10 negative of Melrose Abbey. They each received an exposure of three seconds. The one which was immediately seen to be the finest of all was developed by hydroquinone, two grains, and potassium bromide two grains. This slide is as near perfection as one can hope to attain. The next best was developed by amidol and bromide, of each two grains. This scarcely equalled the former as regards tone, but still is of a quality that will satisfy the fastidious. In the next, the amount of bromide was reduced to one grain, which produces a sky slightly obscured. The obscuration of the lights is further increased when two grains of potassium ferro cyanide took the place of the bromide, the amount of amidol remaining the same. This veiling is still more pronounced when the amidol was used without either bromide or ferrocyanide. The conclusion we deduce is, that equal parts of hydroquinone and bromide, or amidol and bromide, give, at any rate, with the plates mentioned, singularly fine results, although the blacks obtained with the former of these are rather more delicate and warm.

FORTHCOMING EXHIBITIONS.

November 10–12..... *Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, South West-road, Leytonstone.
" 15–17..... *Hackney Photographic Society. Hon. Secretary, W. Fenton Jones, 12, King Edward-road, Hackney.
" 17–19..... Brixton and Clapham Camera Club. Hon. Secretary, F. W. Levett, 74, Geneva-road, Brixton, S.W.
North Middlesex Photographic Society.
" 18–26..... *Stanley Show (Photographic Section). Hon. Secretary, Herbert Smith, 29, Finsbury-pavement.
" 23–25..... *Tunbridge Wells Amateur Photographic Association. Hon. Secretary, Joseph Chamberlain, 14, Calverly Park-gardens, Tunbridge Wells.
" 24–26..... *Exeter Amateur Photographic Society. Hon. Secretary, J. Sparshatt, Fairfield House, Alphington-road, Exeter.
*South London Photographic Society. Hon. Secretary, C. H. Oakden, 51, Melbourne-grove, East Dulwich, S.E.

* Signifies that there are open classes.

THE ALMANAC.—NOTICE.

Intending contributors to THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC *for* 1893 *would favour us by taking notice that their articles should reach us not later than Monday, October* 31.

The publishers desire us to inform advertisers that it has been found necessary to fix Tuesday, October 25, *as the last day for receiving advertisements.*

CONTENTS.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1695. Vol. XXXIX.—OCTOBER 28, 1892.

IMPROVING THE TONE OF BROMIDE PRINTS.

At the close of a recent leading article on the subject of *The Restoration of Faded Albumen Prints* we mentioned the treatment therein described as a possible means of remedying defects in the colour of developed gelatine prints. Since those lines were written an unusually favourable opportunity has presented itself of putting the process to a practical test in that direction.

In turning over a number of old prints we came across a parcel of pictures printed upon gelatino-bromide paper some four years ago, and representing the results of some experiments in obtaining "sepia" tones. So far as we can recollect without reference to an old note-book, the prints after development were treated with mercury or chloride of copper, and the bleached image then darkened by means of various agents, but so far as we remember sodium sulphite was the salt that produced the best results, and was that, in all probability, used in the case of all the prints found. The bleaching agents may have been varied; indeed, from the difference in their behaviour at the present time, it seems pretty clear that such actually was the case.

Whatever may have been the quality of the tones obtained at the time, either from change or from more recent improvements in methods, they did not now strike us as being anything to boast of, and some of them were stained and spotted as if from contact with moisture, though we know that to have been impossible. At any rate they seemed to offer a good chance of putting to the test the restoration method we recently published for albumen prints. The only doubt that presented itself was whether, after having been once submitted to the bleaching process by means of such substances as mercuric or cupric chloride, they would still be amenable to the newer treatment.

One of the worst prints of the batch was therefore selected for preliminary experiment, and was divided into several pieces for separate treatment. These were all bleached in the same solution of bichromate (as formulated in the article referred to), and after careful washing redeveloped with different solutions. The results varied slightly according to the developer used, but in every case the image obtained was of a most satisfactory character and an immeasurable improvement upon the original. Further, not only was that the case, but the irregular markings which had developed themselves since the former treatment entirely disappeared under the process of renovation, and so completely that it was impossible to detect the slightest trace of them after the prints had been dried.

The preliminary trial proving so satisfactory, the remainder of the pictures were bleached in the same manner, and, after washing, redeveloped with a solution containing half a grain of amidol and five grains of sodium sulphite in each ounce. The majority of them turned out perfectly satisfactory prints of the favourite cool grey tone, the exceptions—having evidently undergone different treatment previously—acquiring an increased density that rendered them too heavy in the shadows, though the general tone was a rich neutral black.

This experiment is interesting as showing that the previous treatment of the prints does not unfit them for restoration by the process we have described; and it is quite possible that by varying the redevelopment the darker prints might have been made to render a better result.

Another experiment shows the elasticity of the process. A developed gelatino-bromide print—the portrait of Princess May, published in our Almanac of 1889—was selected for treatment, the desire being to convert it to a *warm* tone. The result was attained, a light brown image being the result; but, as this proved to be eminently unsuited to such a delicate print, the treatment was repeated with the final result that the print is indistinguishable from others that have not been touched.

MYSTERIOUS MARKINGS ON NEGATIVES.

Since the publication of our article last week, and *apropos* Mr. Bennett's communication on another page, we have had brought before us a number of cases of markings that may well be classed under that heading; some of them remain mysterious still, while in others the enigma has been solved. Let us narrate the former instance first, and leave the solution to such of our readers as are able to accomplish it. A worker, whose ability, carefulness of manipulation, and experience none would be inclined to doubt, had in use a large batch of plates (half-plate size) which were admirable in every respect save for the appearance of a certain class of mark, which marred the appearance, and occasionally destroyed the value of sundry negatives. These markings took the appearance of arcs of a circle cut by the edge of the plate, and were almost transparent. It seemed fairly certain that they were drying marks in the manufacture of the plate, for they appeared nearly always on the narrow side of the plate, whichever might be the direction the finished negatives were racked for drying. Further, in some instances, plates of the same batch were noted, where two were evidently cut from one larger piece, and on them the markings were continuous when the two plates were placed together, as they were when in one piece before being cut into two. At least, three or four out of every dozen exhibited these marks, and ultimately a complaint was made to the manufacturer. At his request a dozen plates were initialled by the photographer, sent on to the maker, and by the latter exposed and developed. Result—not

a mark! a mere faint trace in one plate! Not satisfied, the photographer exposed a second dozen himself, and initialled and despatched them as the first. The result was identical—no stain or mark, or, if any, the faintest trace! The mystery to be solved is, "What variations in the modes of development could have resulted in these drying marks being developed up by one person and not by another?" The only feasible suggestion so far received is, that sulphite was used in one but not in the other case, and that its presence interfered with the penetration of the solutions, and so permitted irregular conditions of the film to more readily influence the development. We must confess, knowing as we do the *bona fides* and the skill of the photographer who had this experience, that we are quite at a loss to understand why the markings should appear under his hands and not under those of the manufacturer.

The next case is rather singular, and as it only last week met with an explanation, we at once put our readers *en rapport* with all the circumstances, as the experience is one that might happen in any studio and fail to meet with an explanation, and again a plate-maker be unjustly blamed.

In this instance it was a professional photographer, who uses a large number of plates, who underwent the annoying troubles we will narrate. He had been working with one make of plate for nearly two years without any fault to find, until, upon the receipt of a new batch, he found a great number of the plates were almost useless through the presence of a number of small semi-transparent spots, mostly uniform in size, though some few were larger and others smaller than this average size. He is not given to complaining of his plates when anything goes wrong, as, he tells us, a long experience has taught him that it is not often that the plate-maker is at fault, though he may appear to be. However, the defect continuing, he sent the plates back, and received in exchange a fresh batch. The first few plates seeming all right, he at once proceeded to work in the usual manner. It must here be noted that these spots were too small to be visible in the dim light of the dark room, and could only be discerned after fixing the negative. His alarm may be imagined when, out of a large batch of negatives, a considerable proportion were defective again, just as those first described. In sending an exchange batch, the maker had sent word he did not see much the matter with the plates, and, knowing his trustworthiness, our informant investigated the matter still further. He discovered on one plate a few minute brown translucent particles, which, at first glance, suggested the splashing of some chemical or varnish. This he was certain could not have occurred. A rigid scrutiny caused a suspicion to arise that these specks consisted of something of the nature of asphalt. Here was the solution of the mystery. The development of this gentleman's plates was performed in wood dishes lined with black japanned *papier mâché*, which had been in use about two years. A close examination revealed the fact that on two of these dishes the japan had apparently blistered off, and in exceedingly small blisters, which, each time they were subjected to slight friction, sometimes even the pouring on and off of water, broke away in small, almost invisible, fragments. During development, although the film was always brushed with a camel's-hair brush at the commencement of the operation, these particles attached themselves to the film and partially arrested the action of the solution around them.

This is one of the strangest tricks of development ever brought under our notice. It will be observed that the sinning particles were not visible before development, they were washed away before fixing, and nothing but chance led to their being discovered at all.

If a moral were to be drawn from this account, it would be that plate-users should be more careful than ever before complaining to the manufacturer of any defect in the plates the latter has supplied.

THE COMPARATIVE HARDENING EFFECTS OF COMMON AND CHROME ALUM.

A CORRESPONDENT, writing with reference to our leading article of August 5 last, on "Clearing Solutions," asks us to give him a rough idea of the strength of chrome solution that will harden gelatine films as much as a five per cent. solution of potash alum. The question is not an easy one to answer in a definite manner, since it would involve a careful examination of the precise effect produced by the respective salts under similar as well as under varying conditions, though, for all practical purposes, we may be able to give such information as may be useful to others as well as our correspondent.

We may premise, however, that our reason for recommending chrome alum in preference to ordinary or potash alum in the clearing solution for negatives or prints was that it seems to offer less chance of setting up injurious reactions that may lead on the one hand to immediate staining, or, on the other, to ultimate fading or destruction of the image. We have frequently directed attention in these pages to the decomposition that occurs when solutions of potash alum and sodium hyposulphite are mixed together, and have pointed out the danger that may arise from applying an alum solution—with or without the addition of acid—to a film containing unremoved hypo. But in addition to this, the presence of small traces of ammonia, or of alkaline carbonates, left in the film by imperfect washing after development, will suffice to cause a precipitate which is afterwards very difficult to remove from the gelatine.

Chrome alum, despite its name, contains no alumina, and is therefore free from these dangers, and though, under some conditions, its solution may be made to throw down a precipitate of insoluble chromium compounds, these conditions are not likely to arise in actual practice, and this, in conjunction with the fact that a weaker solution is equally effective, renders it, in our opinion, a more desirable agent than potash alum for most purposes where the latter is employed.

So far as the two salts have hitherto been used in connexion with gelatine for photographic purposes, chrome alum has been usually employed as an addition to solutions of that substance when a hardening action was necessary, while ordinary alum has generally been used as an application to films already formed, whether on paper or glass, to effect the same purpose. Thus chrome alum is added to gelatine emulsion to confer toughness on the resulting films, and prevent their softening during development, and it is also employed in the manufacture of the "single-transfer" paper used in carbon printing, and for a variety of similar purposes where an insoluble film of gelatine is required. Potash alum finds employment, on the other hand, for hardening and rendering insoluble Woodburytype and similar prints, as well as the different varieties of gelatino-bromide and chloride films of more recent introduction. This difference in their uses is justified in what we have already said, by the fact that common alum is more liable to produce insoluble compounds with gelatine than the chromium salt.

And now, with regard to their relative solubility. That of potash alum, as given in our list of solubilities in the ALMANAC, is, perhaps, rather below the mark. One part of alum is there stated to be soluble in 10·5 parts of *cold* water, which is a somewhat indefinite term; as a matter of fact, that is the degree of solubility at 50° Fahr., whereas a temperature of ten or twelve degrees higher is usually that accepted as the "ordinary" temperature in chemical matters. At 60° Fahr. it is soluble in, as nearly as possible, eight parts by weight of water, or one hundred parts of water will take up twelve and a half parts of potash alum; while soda and ammonia alums, which are occasionally met with in commerce, are much more soluble, especially the former. A saturated solution of potash alum, then, at the ordinary laboratory temperature, will contain about sixty grains to the ounce, though in the majority of photographic dark rooms the contents of a saturated solution will seldom be more than fifty grains to the ounce, and at the present season, in all probability, very much less. We have often spoken of the uncertainty that may arise from the employment of "saturated" solutions, and this is only one more instance of the unwisdom of the practice.

Chrome alum, which does not figure in our list of solubilities, requires a little over seven times its weight of water at ordinary temperatures to effect its solution, and for all practical purposes may be said to be of the same solubility as potash alum. But it differs from the latter in being far less variable in its strength with the temperature. A hot concentrated solution on cooling shows very little tendency to deposit any crystals, and a considerable time may elapse before any such are thrown down, while a solution saturated at sixty degrees would probably remain unchanged if the temperature were reduced nearly to freezing point; so that it becomes very necessary to consider the question of temperature in making any comparisons between the action of the two salts in saturated solution.

This, however, is scarcely necessary; for, though we have never made any attempt to gauge their relative strengths with any accuracy, we believe we may say with perfect safety that the chromium salt is very much the more powerful of the two. The ordinary alum clearing solution, as given in the text-books, consists of a saturated solution of the salt with an addition of either hydrochloric or citric acid; but, if a saturated solution of chrome alum were employed, the action would be so powerful that the gelatine film would be rendered almost, if not quite, impervious to any subsequent treatment that might be necessary. In other words, it would be rendered so hard and so completely waterproof that any fixing or intensifying solution afterwards applied would be unable to penetrate it. Such was our experience some years back when experimenting with concentrated solutions of chrome alum, besides which mechanical difficulties are introduced in employing this salt in too strong solution.

Roughly speaking we should say chrome alum is at least five or six times more powerful in its hardening action when applied in solution to a gelatine film than ordinary alum, and that a one per cent. solution will satisfy all the ordinary requirements for either plates or paper. When used in conjunction with an acid or an acid salt, as in the clearing solution mentioned in our article of August 5, its action may be to some extent modified, and it may possibly be desirable to slightly increase the quantity, the actual proportion of the constituents of that solution as we use it, being:—

Chrome alum	2 to 4 drachms.
Metabisulphite of potash	2 ounces.
Water	20 ounces.

the quantity of the first named being increased according to the hardening effect required or the "softness" of the film in use.

If the metabisulphite be not at hand, four ounces of sulphite of soda may be substituted for it, and sufficient hydrochloric or citric acid added from time to time to make the solution smell distinctly of sulphurous acid.

Tennyson's Portraits.—There was but one Tennyson; but, to judge from the portraits of him that have appeared in the various illustrated periodicals, he must have had many faces, so wonderfully unlike one another are some of the pictures. This, we suppose, will ever be the case while draughtsmen and hand engravers have to be relied upon. Unfortunately, "process blocks" in half-tone at present do not fulfil the conditions necessary for rapid machine printing.

Disused Methods.—Forgotten processes formed the subject of a paper at the last meeting of the Birmingham Photographic Society, and an interesting one it is. The officers of most societies find a difficulty in providing subjects for their meetings. Now there are many processes in connexion with photography that have become obsolete and forgotten, though they possess real merit. Papers or discussions upon many of them would prove exceedingly interesting, and often useful—useful if only in saving the time of some enthusiasts in reinventing them, as is frequently being done nowadays. There is little doubt that several processes become obsolete simply because they were introduced at the wrong time. Some of the photo-mechanical processes might be quoted as an example, also Aristotype paper.

Transformation of Gallic Acid into Pyrogallol, Melting Point of Pyrogallol.—M. P. Cazeneuve says that, if we add to gallic acid double its weight of aniline, the mixture, which is at first liquid, solidifies abruptly with a rise of temperature. Thero is formed, doubtless, aniline gallate. If the mass is heated, we observe at about 120° a regular development of carbonic acid without appreciable rise of temperature. At this temperature the whole of the gallic acid may be decomposed. On heating to 180° and cooling, aniline pyro-gallate is obtained in long crystalline needles very instable. Most of the liquid aromatic amines form an equally favourable medium for the transformation of gallic acid. The melting point of pyrogallol is 132° (not corrected), and not 115°, as asserted in the text-books.

A Suggestion.—The appeal of the Secretary of the Photographers' Benevolent Association for subscriptions—and it is to be feared that, from the present outlook, they will be sadly needed—comes opportunely at the time when the different photographic societies are arranging their winter programmes. Now, the suggestion we would make, and we have made it before, is that each society should devote an evening to an entertainment amongst its members and their friends for the benefit of this deserving institution. There are something like two hundred and fifty photographic societies in the United Kingdom, and, if each were the means of raising only a pound, the income of the Association would be more than doubled. No apology is necessary for once more directing attention to the subject, we hope with better result than hitherto.

Do Plates Deteriorate by Keeping?—"Prevention" writes to *Nature*: "I have found great difficulty in obtaining fresh photographic dry plates of whatever maker from dealers, who frequently pass off upon the purchasers packets of plates which have been in stock for a long time, and consequently unfit for use. It has therefore occurred to me that this trouble might be avoided by the

makers dating every packet as issued by them, thus following the custom of the Platinotype Company with their tins of paper. By such a system the purchaser would be able to protect himself, and many makers' plates would be found much more satisfactory." Underlying "Prevention's" idea, which most business men will be inclined, for obvious reasons, to regard as impracticable, is the oft-exploded fallacy that fresh plates are preferable to old plates for no other reason than that they *are* fresh. Provided the method of packing employed is unobjectionable, it remains to be proved that plates (as "Prevention" alleges) "which have been in stock for a long time" are "consequently unfit for use."

Retouching and Bad Trade.—At a recent meeting of one of the metropolitan societies, where Mr. Redmond Barrett discoursed on retouching, one of the speakers in the discussion said that he thought that, on the whole, retouching had been a great affliction to photography, and was the cause of the great depression in photographic portraiture. This statement will take many by surprise. Where is the photographer who would think of submitting a portrait if the negative had not been more or less dealt with at the hands of the retoucher, and what would be the result, from a business point of view, if he did? It is quite true that retouching has tended to the deterioration of the technics of photography, as now many negatives are passed which would be worthless but for the retoucher. The question is, however, one of demand and supply. The public demand highly retouched portraits, and the enterprising professional supplies them. In most instances it is simply a matter of £ *s. d. versus* rough truth. Attempting to educate the public, a well-known portraitist recently remarked to us, is not remunerative. It likes to be flattered, and is accommodated, adding, "We are not like the Chinese artist, who, when called upon to paint the miniature of an English lady, put the following query: 'Ladee, likee likee, or likee beautiful?'" We take the latter for granted. We fear that the cause of the depressed state of portrait photography must be sought for in another direction than retouching.

CONTACT PRINTING.

How simple, and yet how little understood by the great bulk of those who are daily to be found resorting to this method of producing lantern slides from their negatives.

Contact printing is generally understood by a great many who are not only beginners, but also by old and experienced workers, to mean the mere placing of a sensitive plate in contact with (or portion of) a negative for the purpose of printing a positive picture, and, doubtless, owing to the extreme ease of such procedure, the entire operation has come to be looked upon as one requiring little thought or akill on the part of those who are conducting the operation. It generally resolves itself into placing the two plates in contact in a printing frame, turning up a naked gas-flame at an ordinary gas-jet, holding the frame at an uncertain distance from the light (the proper distance generally being considered to be about twelve or fifteen inches from the flame), then to develop, and in ninety-nine cases out of a hundred trusting to luck for the results being up to the mark.

Such is, no doubt, the *modus operandi* followed by hundreds, if not, indeed, thousands of amateurs who take no small amount of pride in showing off their handiwork. True, some little thought on the surface of the operation seems to be bestowed on the question of how many seconds exposure ought such and such a negative to get, but otherwise the operations are very much as I have mentioned.

Now, this is not contact printing as it ought to be conducted, and is just about as careless or thoughtless a way of conducting the operation as it is possible to conceive; but, nevertheless, it is just a point where those who have not had the benefit of learning a trade or profession begin at the wrong end of the stick, or, in other words, attempt to learn an occupation by working downwards, instead of beginning at the bottom and working upwards.

Contact printing, properly understood, is not the simple matter that many suppose it to be, and I sometimes think that more thought and consideration is required in practising it than in very many other branches of photography. Doubtless, in many respects, such printing closely resembles numerous points that have to be observed in ordinary daylight printing, such as when albumenised paper is being employed in an ordinary printing-room of the studio (and perhaps the printing-room, all being considered, is the most important corner of any studio), and not, as many suppose, merely a secondary consideration in a photographic business. I look upon the head printer in an establishment as king over all others employed.

Now, what is the very first act of a printer who has sent up to him a batch of negatives to print? Certainly not hurrying such off into the printing frames, placing in contact with the paper, and without giving any heed or consideration to this or that particular feature in a negative, placing them all out to print in exactly the same light and under exactly the same conditions. Such is not the way an experienced printer sets about his work. He knows better than to follow such a happy-go-lucky style. With him each negative is taken singly and minutely examined, first for the merest flaw possibly overlooked by the retoucher. Then these are assorted into different classes; such-and-such must receive quite different treatment to those others—in fact, they are all subjected to a close scrutiny, and very possibly some may be printed upon paper of varying qualities depending upon their densities. Others, again, require thoughtful consideration in the way of being printed through varying depths of shields, sometimes ground glass or tissue paper; others, again, have to receive very careful attention in printing by being judiciously dodged—in fact, a printer's occupation is no sinecure, and, if such is necessary in the practice of slow or daylight printing, how much more so is it when such rapid work as contact printing by after development is being followed?

Here we are face to face with negatives of ever-varying density and colour, not two of which print alike, yet still, as we have seen, the common practice is to expose all such twelve inches from a naked flame; some, perhaps, a few seconds less or more than others, according to their appearance of density. Now, if the best results are to be obtained by contact printing, it certainly is not by following such a slip-shod method of working.

First in importance comes the nature of the light to be employed. Gas is perhaps, all being considered, the best light to employ, but certainly such should never (or very rarely indeed, if ever) be used as a naked flame. Let a beginner who cares to enter fully into the pleasures of contact printing begin by carrying out a few simple experiments on the following lines:—

First, let him provide an ordinary bat's-wing burner fitted to some suitable gas-bracket or stand, that will enable such to be placed on an ordinary kitchen-table, the centre of the flame when placed in a fixed position being about six inches from the bottom. Let the light be turned up at its best. Next, let him take the thinnest negative that he can obtain, and proceed to make an exposure after the method described, viz., by holding the frame in his hand for a certain number of seconds, judged to be about the correct exposure; then let the plate be developed, and it is just about a hundred to one the result will be declared not good, bad, or very likely useless. Why? Because a very thin negative has been employed, and the light used has not been suitable for such, neither have other necessary conditions been followed (conditions which I hope to allude to later on).

It is interesting to follow what would have been the procedure with such a negative were it placed in the hands of an experienced printer for daylight prints. Certainly such a negative would never have been placed out to print in the full blaze of sunlight, or diffused light either for that matter, without having received some shielding from tissue paper or ground glass. And why such treatment? Simply because an over-powerful light would completely drown, in this case, the meagre gradations of the negative, or, in other words, the denser and thinnest portions of the negative would go on printing in equal proportions simultaneously. To prevent this, the common practice of shielding, or of employing a weaker light to print does much in the way of permitting only just the correct amount of light being used as will permit of the denser portions of the negative being much more slowly printed than the thinner portions. When such is the method employed, a fair amount of contrast will be obtained—a result quite impossible to get when too much light is employed.

This is the first and most important principle to grasp in contact printing, and, once it is understood and acted upon, a marked improvement will be noticeable in the results turned out.

I veritably believe that every negative has a special light of its own, that is best suited for its peculiarities.

Bearing this in mind, next let the beginner take the same negative and proceed to print it under different conditions. Let him try the result of placing in front of the naked gas flame, at a distance of, say, six inches, a sheet of ground glass; then let the printing frame containing the negative and a similar plate in contact as was previously employed be reared on end at a distance of, say, two feet from the flame, and let the same exposure be given as previously. Now let the plate be developed by any formula the working of which is best known to the operator, and judge of the difference in the results. Very possibly a decided improvement in contrast will be the outcome

of even this the first experiment. If the plate develops up somewhat rapidly, it is but safe to conclude that still better results can yet be obtained; therefore proceed again, but this time turn down slightly the light, giving the same exposure and at the same distance, and further, when developing, add a grain or two more pyro (I am a firm believer in pyro for developing lantern slides), and a drop or two of bromide; watch closely on development. This time the picture will very likely come along more business-like, and an amount of contrast or building up of gradation obtained far and away in advance of anything ever dreamt of as being possible of attainment from such a negative. Doubtless, also, much power for good lies in the manner in which such an exposure be developed. Here we have a great power at hand.

Thin negatives, as a rule, require extra pyro and bromide, and when such are made to dovetail with exposure to just the correct amount of light, and only a very slow plate is employed, it is quite wonderful what results are obtained from negatives from which many are unable to obtain even passable results.

So much for the treatment of a thin negative. Now let us take the case of a very dense one. Here we have almost exactly opposite factors to work with. In the former case the high lights (dense portions of the negative) printed up too rapidly; now it will be the reverse. Provided the same conditions of lighting and distance be employed, the high lights will not print up in anything like the same time as the less opaque portions of the negative; in fact, it is just possible to employ such a weak light that would never penetrate through even some of the middle tints of a negative. Therefore, a more powerful light must be brought into play in such a case, and in very extreme cases of density a very rapid bromide plate will be found to yield even better results than a slow lantern plate, for in this case the chief aim is to keep down contrasts. I notice that rapid lantern plates are now on the market; doubtless these will be very useful in many ways, especially when negatives have to be reduced through the camera by artificial light.

In cases, therefore, of extreme contrast in negatives, the full flame of the gas-jet may be employed, always using the ground-glass intermediate screen, and frequently the frame containing the negative or plate may, with advantage, be brought much nearer to the light, and a weaker developer employed; by such means extreme contrasts will be avoided.

Contact printing, when properly understood and conducted, will often yield very good results, but at no time, in my opinion, ought such to be employed if the work is capable of being produced through the camera. I have repeatedly had cases of want of sharpness brought under my notice that were clearly attributable to uneven glasses, and sometimes, also, from faulty manipulation, by the printing-frame not being held steady during exposure. When such were printed through the camera, it was surprising to witness the great difference in sharpness of the slides.

Another oversight in the practice of contact printing is the non-employment of a suitable frame for printing in, and, in many cases, the non-preparation of a negative for a particular class of printing.

T. N. Armstrong.

AMERICAN NOTES AND NEWS.

A Real "Detective" Camera.—An alleged pickpocket, we read, recently arrested in Hartford, Conn., made it so difficult for a photographer to take his picture, that the officers hit upon the happy expedient of having a snap-shot taken, unknown to him, while walking through the street. The amateur who performed the operation succeeded in getting an excellent picture of the prisoner and of the officer who was with him. Needless to say, this happy result was not placed on exhibition in the rogues' gallery.

Starch as a Mountant.—"After many years' practice in photography," says Dr. Ellerslie Wallace in the *American Journal of Photography*, "and close watching of the behaviour of prints mounted with different substances, I feel perfectly safe in recommending simply starch well boiled in preference to anything else. I have been greatly disappointed in the permanency of prints mounted with gelatine in any manner, either upon cards or upon glass. Solutions of gelatine with alcohol are elegant preparations for mounting, and work very smoothly under the brush: the only drawback is the very serious one of affecting the permanency of the print. Mountants containing glycerine are even more to be feared, from the fact that glycerine always attracts water, and is sure to retain any dampness present in the print, even if the latter is seemingly quite dry."

The Hardening Effects of Chrome Alum.—According to Wilson's *Photographic Magazine*, Dr. J. J. Higgins, of Philadelphia, renders gelatine negatives absolutely insoluble with chrome alum "in proper combination." Immediately after fixing, it is said the plate can be freely flushed with boiling hot water without the least danger of its slipping or removal from the glass support, or affecting the image in any way. This remarkable phenomenon all hinges, we suppose, upon the use of alum in "proper combination." whatever that may be.

Departure of Miss Catharine Weed Barnes.—Miss Catharine Weed Barnes sails for New York on Saturday next by the Inman liner, *City of New York*. In taking leave of her a few days since, we were glad to hear that, although during her stay in this country she had accomplished an immense amount of photographic work, her visit had proved most enjoyable to her.

The Canadian Photographic Exhibition.—The first meeting of the Annual Convention of the Photographic Association of Canada was held on September 8, in Toronto. Over $495 in gold, besides trophies, &c., were offered for competition. Many of the principal American firms "donated prizes," and we read that the exhibits afforded an interesting proof of the rapid progress, in nearly all branches of photography, which has been made in comparatively recent years. Before the business meeting closed, Mr. Knowlton informed the members that the Stanley Dry Plate Company, Montreal, which he represented, would raise their donation from $100 to $250 for next year. Mr. Anderson, for the Eagle and Star Plate Company, caused some amusement by saying that he would go Mr. Knowlton ten cents better. American manufacturers are enterprising men of business!

A Difficult Sitter.—"Perhaps," says *Anthony's Bulletin*, "one of the most unusual subjects to be photographed, of which we have read, is a large South African crocodile, which was surprised by a party from one of the missions there while out on a sporting tour, and photographed by Mr. F. Moir. We may say that Mr. Moir was ably seconded by four native blacks, who assisted the subject to sit, as without their services he would have run off the plate before he could have been 'taken.'"

A Retouching Medium for Albumen Prints.—On the authority of the *Photographic Times*, a very good retouching medium for albumen prints is made by macerating half an ounce of soap bark (*Quillaija saponaria*) for two hours in boiling water. After filtering the infusion, add four ounces of alcohol and a quarter of an ounce of salycilic acid. When applied to albumen prints, Indian ink and water colours take well to the glossy surface.

The Photographic "Globe Trotter."—Our old friend, W. K. Burton, has a word or two to say on this subject in the pages of an American contemporary, to which he contributes a gossiping collection of "Notes from Japan." "Of the globe-trotting amateur," he says, "we have enough and too much at various times of the year. He is often an unmitigated nuisance; he knows little or nothing of photography, but has some hand camera or other with which he goes snapping about indiscriminately; he comes with a note of introduction or without: he has made 40 or 400 shots—'quite interesting, you know,' and 'would like to see what they are like.' 'Would you mind developing them for him?' . . . . This is one kind of the species. There is compensation for the multitude of him in the occasional arrival of an old friend, of one known by reputation, or of one whose fondness for knowledge of photography makes it a pleasure to talk with him. Especially delightful is it to us if a man comes from any of the far-away countries with all the gossip—nay, the slander—of the societies and clubs, the things that do *not* get into any of the photographic periodicals." Now, now, Professor!

YELLOW FOG.

The cause of yellow fog, says the *Photographic Times*, is now well ascertained. It is a dyeing action which occurs with pyrogallol, hydroquinone, and eikonogen, by using old oxidised solution, or by long development, the reagent being then in a state of oxidation. There are also other causes which influence the defect in question, but they are not known with certainty.

Sodium sulphite counteracts this phenomenon.

Washing in a solution of tartaric, citric, or oxalic acid, &c., before fixing, prevents the fog from occurring in the sodium thiosulphate (hyposulphite) solution.

Yellow fog can be removed before or after fixation. It can also be removed during the fixing process by the use of the so-called acid bath, one compounded with acid sodium sulphite.

To remove it before fixing, prepare the following solution:—

Sodium sulphite	1 ounce.
Alum	1 „
Hydrochloric acid	160 minims.
Water	8 ounces.

In this the plate, developed and washed, is immersed for a period of three or four minutes, then fixed in a bath of sodium thiosulphate at 1:4.

To clear the negative after fixing is often a difficult operation. Of all the processes which were published, one of the best is that recommended by Mr. E. Garbe. According to the author, it is based on the action of nascent sulphur dioxide generated by the influence of air and moisture on sodium thiosulphate. We think, however, that the decolouration is due to another cause, for the sodium salt, in the circumstances in question, is decomposed thus:—

$$Na_2S_2O_3 + H_2O = Na_2SO_4 + H_2S.*$$

* This we give on the authority of Wurtz. If sulphurous acid is formed, then the action should be represented as thus:—

$$Na_2S_2O_3 + O_3 + H_2O = Ns_2SO_4 + H_2SO_3.$$

Whatever it may be, here is the process of Mr. Garbe, described by himself in the *Photographic Gazette*:—

We prepare the mixture following:—

Glycerine and water, equal parts, in which is dissolved in the cold sodium hyposulphite to saturation (from forty to fifty per cent.).

This mixture is spread with a brush on the yellow negative, then the plate is set aside on a level surface, sheltered from the heat and dust. According to the intensity of the colouration, the yellow tint infallibly disappears in a more or less long period, which may vary from one to twenty-four hours. Here again, it is the *nascent* sulphurous acid which acts in consequence of the oxidation of the hyposulphite in contact with the air. This is so much more evident that the same negative is not discoloured if immersed in a bath of hyposulphite, because the action of the air does not exist on the surface of the negative.

The means which we speak of have already been indicated, but with a solution of hyposulphite in water only, and it happened that from the evaporisation of the water incrustations were formed on the surface of the gelatine film. The object of glycerine is to increase the proportion of hyposulphite dissolved, and to prevent the crystallisation even after a very long period.

By this process we have decoloured negatives which were so yellow that one could hardly see the image, and which were dry for more than two years.

SIMPLE CHEMICAL ANALYSIS.

[Holborn Camera Club.]

The subject on which I am going to speak this evening is one, I think, which should be of interest to all working photographers. The knowledge of chemical analysis to a photographer is a powerful weapon to fight the many difficulties in which the path of photography runs. And, again, this knowledge will give him the means to enable him to test his tools by which his work is produced. (In reference to tools here, I mean such solutions as may be used to produce certain results.) It is, I think, needless for me to dwell upon the many advantages which will arise to those who have the power of being able to detect any of the substances which they may use in their work. It will therefore be my endeavour to show you that this subject is not one which is beset with any great difficulties, but is one which is quite capable of being manipulated by any one who possesses an average amount of intelligence.

Hints to Tyros.

I will now proceed with a few short notes, which will be found of use to those who have not done any of this work before:—

(1) When adding a reagent to a solution and a PP* is formed, be sure to add sufficient of the reagent to insure that the whole of that particular substance is thrown down.

(2) Do not hurry therefore if a certain effect is not produced immediately. Do not imagine that the particular substance you are testing for is not there. Some reactions are at once apparent, and others take some little time.

(3) In commencing analysis, always analyse some substance, the composition of which you are aware, and note the effect produced by this of certain defined reagents.

(4) Always test an unknown substance for the base or metal first, and then for the acid which has combined with it. For example, in sodium chloride, the sodium is the base, and the chlorine is the acid which has combined with it. When you have detected the base of an unknown substance, this will give you some idea as to what acid it belongs.

(5) Always confirm the result given by one reagent by testing with another reagent for the same substance. For example, in adding a solution of $BaCl_2$ to an unknown solution, you may get a PP soluble in HCl, and yet it may not be a sulphite; therefore you must confirm the fact of its being a sulphite by the granulated zinc test.

(6) To test with borax beads, place a little borax on the loop of your platinum wire, and hold same in the Bunsen flame; it will boil up, and then fuse to clear glass. Now place a little of the substance to be tested on the bead; heat same, and allow to cool; then notice the colour of the bead. If the colour of the bead is too dark to make out the exact colour, add more borax and heat again; this will lighten the colour of the bead. Chromium is about the only element in every-day use in photography which gives a characteristic colour to the borax bead.

(7) The following is the method of using the platinum wire for flame tests: Hold the wire in the Bunsen flame until it ceases to give the intense yellow colour, then place a little of the substance to be tested on the wire, and hold it at the lower edge of the flame. Sodium gives a very strong yellow colour to the flame; potassium gives a pale lavender colour.

To make a platinum test-wire, take about two inches of platinum wire and double the same in half, then twist together, so as to leave a small loop at one end. Mount this in a small piece of glass tube, so as to form a handle. Taking a test-tube of about half an inch diameter, you fit a cork to it, and make a hole in the cork large enough to take the glass-tube handle. Push the handle through the hole in the cork, partly fill test-tube with weak hydrochloric acid, and, by putting the cork in the test-tube, you have your platinum wire always clean and ready for use.

Apparatus.

The following are the apparatus required for practice of analytical work: test-tube stand, test-tube brush, twelve test tubes, 5 × ½, six test-tubes on feet, one test-tube holder, spirit lamp or Bunsen burner, wash bottle, two small evaporating dishes, two small glass funnels, one packet of filter paper, three inches of platinum wire, two watch glasses, one nest of small beakers, retort stand, one piece of wire gauze, one piece of charcoal, and a blow-pipe. This may seem rather a long list; but, as the whole of the apparatus can be purchased for something like ten shillings, the list is rather more lengthy than expensive.

Reagents.

We will now pass on to the various reagents that we shall require:—Acetic acid, 1 oz. to 1 oz. of water; ammonia, 880 s.g. diluted with about twice its bulk of water; hydrochloric acid, strong; hydrochloric acid, dilute ½ an oz. of acid with 1½ ozs. of water; sulphuric acid, strong; sulphuric acid, dilute, ¼ of an oz., is made up to 2 ozs. with water; nitric acid, strong; nitric acid dilute, ½ an oz. to 1½ ozs. of water; ferric chloride, 20 grs. to 2 ozs. of water; lead acetate, 20 grs. to 2 ozs. of water, and a little acetic acid; barium chloride, 60 grs. to 2 ozs. of water; silver nitrate, 20 grs. to 2 ozs. of water; potassium ferricyanide, 20 grs. to 2 ozs. of water (this solution should be made up as required, as it does not keep); potassium ferrocyanide, 20 grs. to 2 ozs. of water; potassium iodide, 20 grs. to 2 ozs. of water; caustic soda, 40 grs. to 2 ozs. of water; ½ oz. of platinum chloride; lime water; a piece of lime about the size of a walnut should be well shaken up in about 10 ozs. of water, allow to settle, and decant the clear liquid off. With the following dry reagents in wide-mouthed bottles:—ferrous sulphate, sodium carbonate, black oxide of manganese, granulated zinc, together with some red and blue litmus papers, starch and lead papers, and a little borax.

* For explanation of abbreviations see end of paper.

The Detection of Bases.

1. *Silver and Lead Salts.*—All give a white PP when treated with HCl. Add ammonia, if silver PP will dissolve. If the PP is lead, on boiling the solution the PP will be dissolved. Sodium hydrate also dissolves the lead P P.

2. *Mercuric Salts.*—(*a*) Sodium hydrate, when added in excess, gives a yellow PP, soluble in HCl. (*b*) Pot. iodide gives a yellow PP, which changes to a bright red. This PP is soluble in excess of pot. iodide or mercuric salts. (These mercuric salts must not be confounded with the mercurious salt, which gives a white PP with H Cl, which is blackened on the addition of ammonia.)

3. From *Ferric Salts.*—(*a*) Pot. *ferric*yanide give a dark-blue PP, (*b*) sodium hydrate and ammonia a brown PP.

4. From *Ferrous Salts.*—(*a*) Ammonia hydrate gives a light colour green PP, which turns a dirty green and afterwards a reddish brown. (*b*) Pot. *ferro*cyanide gives a blue-green PP, which afterwards turns to a dark blue. (*c*) Boil a ferrous solution with a few drops of strong HNO_3. The liquid becomes black, effervesces, and, turning yellow, becomes changed into the ferric condition.

5. *Sodium Salts* give no PP with platinum chloride, but give the Bunsen flame a very intense yellow colour, which is quite characteristic of sodium.

6. *Potassium Salts.*—(*a*) Place a watch-glass on a piece of white paper, and place a little of the liquid to be tested on it; then add a few drops of platinic chloride and a few drops of alcohol. After a few minutes a yellow PP will fall if the solution is not too dilute. If no PP falls, allow it to rest for half an hour, giving the solution a stir now and then. (*b*) Potassium salts also impart a lavender colour to the Bunsen flame. This colour is not very intense, as the sodium in the air always gives the flame a little yellow colour, which tends to overpower the light colour of potassium. A piece of cobalt colour glass is sometimes used to cut off the sodium flame.

7. *Chromium Salts*:—(*a*) Treated with lead acetate give a yellow PP. (*b*) With silver nitrate a deep red PP is given which is soluble in HCl. (*c*) Chromium salts also give an emerald green borax bead when heated in the outer or inner flame.

The Detection of Acids.

8. *Acetic and Acetates.*—(*a*) Ferric chloride in neutral solutions produces a dep red colour, which, on the addition of HCl, turns yellow. (*b*) On boiling the red solution the iron is PP as a basic acetate, and the liquid becomes colourless.

9. *Citric and Citrates.*—(*a*) A fairly strong solution, if mixed with H_2SO_4 and heated, will blacken, and, if evaporated down, will leave a black syrupy residue. (*b*) Will also PP lead acetate soluble in HNO_3.

10. *Oxalic and Oxalate.*—(*a*) Barium chloride gives a white P P soluble in HCl and HNO_3. (*b*) Silver nitrate gives a white PP soluble in HNO_3 and ammonia.

11. *Hydrochloric and Chlorides.*—(*a*) When treated with silver nitrate it gives a PP which is soluble in ammonia. The P P turns violet if exposed to light. The PP is insoluble in HNO_3. (*b*) See test (1) for lead.

12. *Nitric and Nitrates.*—Take a weak solution of a nitrate, and add equal bulk of a solution of ferrous sulphate in a test-tube. Hold the tube at an angle of about forty-five degrees, and carefully pour down the side of the tube a few drops of strong H_2SO_4. After a few seconds a brown ring is formed at the junction of the two liquids. After it has begun to form, a little gentle shaking assists the formation of same. This is a very delicate test.

13. *Sulphureous Acid and Sulphites.*—(*a*) Barium chloride produces a white PP soluble in HCl. (*b*) Put into a test-tube some granulated zinc, add HCl, let it effervesce, then pour some of the liquid to be tested into the tube. The gas H_2S will be given off, which may be detected by the smell and by its power of turning lead paper black.

14. *Sulphuric Acids and Sulphates.*—(*a*) Barium chloride gives a white PP insoluble in HCl. (*b*) Powder a little of a suspected sulphate and mix with equal parts of powdered charcoal, stir into a paste with a little water, and place the mixture on a piece of charcoal. Heat in the reducing flame for a few moments and take a little of the residue, powder it, and place on a bright silver coin. Add a drop of water, and, if the substance tested was a sulphate, a brown-black stain on the coin will be the result.

15. *Carbonic Acid and Carbonates* (CO_3).—Carbonates, when treated with HCl evolve CO_2 (carbon dioxide). If this gas is led into a vessel containing clear lime water, and allowed to bubble through, the lime water will become milky, and a P P of calcium carbonate will be formed.

16. *Bicarbonates* (HCO_3).—The bicarbonates or hydric carbonates give off carbon dioxide on boiling solutions of these acids. The solids dissolve in boiling water with effervescence. The carbon dioxide may be detected as in the last test.

17. *Thiosulphates.*—(*a*) On adding HCl to a solution and gently warming, a P P of sulphur will fall, with a smell of sulphur dioxide. (*b*) Silver nitrate gives a white P P soluble in HNO_3. This P P is blackened on heating.

18. *Bromides.*—(*a*) On heating with H_2SO_4 and black oxide of manganese evolve bromine, which may be detected by its red colour and its power of turning starch paper yellow. (*b*) Will also P P silver nitrate, insoluble in weak HNO_3 and soluble in ammonia.

19. *Iodides.*—(*a*) Heat as with last test a mixture of H_2SO_4 and manganese, and hold a piece of wet starch paper in the tube. The paper will be coloured purple if iodine is there. (*b*) Iodine will also P P silver nitrate almost insoluble in ammonia.

20. *Ammonium.*—(*a*) All ammonia salts can be volatilised. For example, place a little of some ammonia compound in the end of a long test-tube, heat it, and a sublimate of ammonia will be formed at the other end of the tube. (*b*) To test a solution for ammonia, add caustic soda, heat gently, and ammonia is given off, which may also be detected by its action of turning wet red litmus blue. White fumes will also be given off if an open bottle of HCl is brought near.

21. *Ferrocyanides.*—(*a*) Silver nitrate gives a white P P insoluble in HNO_3 and ammonia. (*b*) Ferrous sulphate gives a P P of blue green.

22. *Ferricyanides.*—(*a*) Silver nitrate gives a P P of orange red, soluble in ammonia. (*b*) Ferrous sulphate gives a deep blue P P, soluble in sodium hydrate.

23. *Cyanides.*—(*a*) Silver nitrate gives a white P P, insoluble in HNO_3, soluble in ammonia. (*b*) Silver cyanide, when heated to red heat, is reduced to metallic silver.

I will now conclude with a brief review of the manner to go to work to detect any of the ordinary chemicals that may be found on a photographer's work-room shelf.

If the substance is a solid which you wish to test, dissolve about twenty grains of it in a test tube with about one ounce of distilled water. This solution is called the original solution. We will now proceed to test for the base. Before, however, proceeding to test the solution of the chemical, place a little of crystal on the platinum wire and heat in the Bunsen flame. Note the colour it imparts to the flame. Now we will proceed to test the solution. Take about one drachm of the original solution, pour into a test tube, and add a little dilute HCl. If you get a PP it may be lead or silver (1). If you do not get any PP, add to another portion of the original solution some ammonia sulphite. A PP in this case indicates iron (3 and 4). If no PP forms, take a few drops of the original solution, and use test for potassium (6). Then test for chromium and mercury (2 and 7). After having found the base, you must then test for the acid which is united with it. The knowledge of the base will give you some idea as to what acid you may expect. It is as well to always use fresh portions of original solution for every separate test you make.

In conclusion, I would ask every photographer who likes a little experimental work to give chemical analysis a trial, and I am sure that he will not only find the same very valuable in his ordinary photographic work, but also a source of pleasure independent of photography. I think an apology is due to you for the rather curious way this paper and tests are arranged. I will ask you to excuse me on the grounds that my aim in the paper has been to make it as simple as possible, and to avoid introducing those chemicals which are very seldom, if ever, used by the ordinary run of photographers. To those who wish to go into this subject deeper and in a thorough chemical manner, I can recommend the following works:—*Analysis of a Simple Salt* (price 2*s.*), published by Cliva & Co.; *Practical Chemistry*, by Tilden (price 1*s.* 6*d.*), published by Longman Green, & Co.; *Qualitative Chemical Analysis*, by Thorpe and Muir (price 3*s.* 6*d.*), published by Longmans; and a far more elaborate and difficult work, *Valentine's Analytical Chemistry* (price 7*s.* 6*d.*), published by Churchill. The following abbreviations have been made use of in the paper.

PP for ..... Precipitate HCl for ..... Hydrochloric Acid
HNO_3 ..... Nitric Acid H_2SO_4..... Sulphuric Acid.

Ernest Benest.

MYSTERIOUS MARKINGS ON NEGATIVES.

In your leading article under this heading last week, when speaking of those cases where fogging was traceable to the dark slide, you say: "As in all wooden shutters mahogany is employed, it can scarcely be imagined that it would exhale anything that would act injuriously

on the bromide film. Hence, if the evil arises from pernicious fumes they must be sought for in the material with which the inside of the shutter is blacked;" and in the two following paragraphs, that when fog only appears on those parts of a negative opposite the wood of the shutter, and the hinge has formed a protection, it is more probable that it is due to the shutters affording insufficient protection to a highly sensitive plate against a prolonged exposure of the slide to a strong light than to exhalation.

Having been occasionally troubled with mysteriously fogged plates for a considerable time after commencing to use a new whole-plate camera, I venture to submit the following facts to you, as they justify the conclusion that fog may be caused by the wood of which the shutter is made, although this may be well-seasoned mahogany.

The camera being frequently used under conditions that severely tested its safety, giving negatives perfectly free from fog, rendered it somewhat difficult to trace the cause, as the real origin of the trouble was not suspected until a plate showed a decided line corresponding to the hinge of the shutter, that part of the negative that had been against the wood being badly fogged, while that that had been opposite the hinge remained perfect. A series of tests were made, with the following results:—

The slides were perfectly light-tight under all reasonable conditions. They were filled with plates, and left out of doors for three hours in the brightest light possible, without allowing the sun to shine directly on them, on a clear day in August. Although the plates were subjected to a prolonged and strong development, they showed no trace of fog.

The plates were fogged if left for any length of time in the slides, though they were kept in the dark. The slides were filled, wrapped in several thicknesses of black material, and put away in a wooden box for three days. On development the plates were decidedly fogged. Others left for seven or eight days under identical conditions were very badly fogged.

The blacking, which consisted of a mixture of French polish and lampblack, was not the cause of the fog, as *only one shutter was blacked*, the other five having been left with the plain surface of the wood inside, simply smoothed with glass paper, and *all fogged about equally*. All the six shutters were made from one piece of wood, and, though the plates were fogged over their entire surface, they were worst at the part corresponding to one side of the plank, as traced by comparing the grain or "figure" in the shutters. The plates of one maker were more affected than those of another, though they were of equal rapidity.

It having been found that an ordinary coating of polish and lampblack afforded scarcely any protection whatever, it was considered necessary to adopt a far stronger remedy. After each shutter was made slightly thinner, a sheet of tested non-actinic paper (that used by Messrs. Wratten & Wainwright for packing their plates) was affixed with very thin glue, and three or four liberal applications of French polish were made with a small sponge at intervals of several days, the shutters being kept well exposed to the air in a warm, dry room. By this method the polish soaked well into the porous paper and wood, and dried with a very hard and fairly dull surface. There is not the necessity for a perfectly dead surface in a slide shutter as in the body of the camera.

Although this remedy sounds clumsy, it is not really so. The surface of the paper is so thoroughly protected by the polish, that twelve months' frequent use has not produced the slightest abrasion. As a cure it is perfect; plates have been kept in the slides for three weeks, then under-exposed and forced in development, without the slightest trace of fog.

Unfortunately, there seems to be a new source of imperfect negatives to be added to those generally suspected and guarded against.

HENRY W. BENNETT.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.

[A Communication to the Royal Society.]

THE Kew Committee of the Royal Society decided, about a year ago, to undertake the examination of photographic lenses, thus adding one more to the already numerous list of tests and certificates issued by the Kew Observatory. Captain Abney was the member of the Committee who originated the idea, and he was requested to organize the system in detail. This he undertook to do, but unfortunately it proved that official duties and his work in connexion with colour vision, &c., made it impossible for him to give the necessary time to the inquiry. In consequence of this, I was asked by the Kew Committee, with the full acquiescence of Captain Abney, to give my assistance in the matter, which I gladly consented to do; eventually the arrangements developed almost entirely upon myself, acting in co-operation with Mr. Whipple, the Superintendent of the Observatory, and aided by consultations with Captain Abney; but I should add that as to the arguments and discussion in this paper I alone am responsible. A very considerable amount of time and energy was expended by Mr. Whipple and myself before the final recommendations could be made, but now, since the whole of the proposals have received the provisional approval of the Kew Committee, it is open to any one to get a photographic lens examined at Kew on payment of a small fee.

It is important first to state clearly the general idea which the Kew Committee had in view when they undertook this new work, for, if the methods adopted are judged from any other standpoint, they will, no doubt, be found open to criticism. The object of the Committee was to organize a system by which any one could obtain, on payment, an impartial and authoritative statement of the quality of a lens to be used for ordinary photographic purposes, and that the fee, which had to cover the cost of the examination, should be moderate. This latter consideration acted as a serious restriction, and it was consequently necessary that all the tests should give results of undoubted practical value to the practical photographer; the certificate of examination must be recorded in the way most generally useful, and in language which could not fail to be understood. A complete scientific investigation of a lens from every point of view would occupy so long a time as to make the necessary fee quite prohibitive, and, moreover, the results would contain much information which would be quite useless to the ordinary user of the lens.

There are undoubted advantages in testing a lens by the examination of negatives made by it, but it may be here stated, once for all, that the question of expense rendered it impossible, for the present, to adopt any photographic method; eye observations alone have to be relied on.

The form of entry is made to state for what special purposes the lens is intended, whether for portrait work, for landscape views, or for copying plans, &c. Every lens for photographic purposes is more or less of a compromise. Great rapidity, great perfection in definition, and power of covering very wide angles are incompatible qualities, and one or other of them must be sacrificed. It is therefore evidently unfair to expect different types of lenses to give equally good results under the same test; for, if we select a lens excelling greatly in one of these qualifications, we must deliberately abandon the expectation of its attaining the highest standards in the others. For example, in a portrait lens great rapidity is required; but, on the other hand, a less high standard of definition near the edges of the plate can be tolerated than with a landscape lens. No opinion could possibly be expressed at Kew as to the wisdom of demanding extra perfection or powers in any respect, and it is therefore necessary that the lenses should be, to a certain extent, classified by the parties sending them in for examination.

The smaller the aperture of a lens, the larger will be the field of sharp definition covered by it, and a complete study of a lens would tell us the size of the plate which is properly covered when each of the different stops is used. Considering the restrictions necessarily imposed on the work, such a lengthy examination could not possibly be thought of. Hence, when discussing the programme of tests to be applied at Kew, it was soon evident that the time devoted to the examination of each lens had to be limited by making the person entering it state either the number of the largest stop by which it should be judged, or the size of the plate for which it would be used; on the first supposition, the Kew certificate would have given the size of the plate which the lens covered satisfactorily with the named stop; and, on the second supposition, it would have indicated the size of the largest stop that could be used to give results up to a certain standard, or the rapidity of the lens in normal cases when used for the plate of the named size. The latter of these two alternatives has been adopted, because it is considered that the owner or intending purchaser of the lens will, in most cases, have already decided on the size of the plate he intends to use, and that what he wants to know is whether it is suitable for that plate or not. When further information is desired, the lens may be entered for examination for two or more sizes of plates.

The following is an example of the Certificate of Examination, the part in italics representing the result of the testing of the lens.

KEW OBSERVATORY, RICHMOND, SURREY.

Certificate of Examination of a Photographic Lens.

1. Number on lens, 3876. Registered No., 95.
2. Description, *landscape lens*. Diameter, 1·5 inches.
3. Maker's name, *A. B.*

4. Size of plate for which the lens is to be examined, 6·5 inches by 8·5 inches.
5. Number of reflecting surfaces, 4.
6. Centering in mount, *good*.
7. Visible defects—such as striæ, veins, feathers, &c., *nil*.
8. Flare spot, *nil*.
9. Effective aperture of stops.

Number engraved on stop.	Effective aperture. Inches.	*f* number.	C.I. No.*
No. 7·5	1·32	*f*/5·6	1/1·38
No. 10	1·19	*f* 9·5	1/1·12
No. 15	0·97	*f*/11·7	1·35
No. 25	0·75	*f* 15·1	2·26
No. 50	0·49	*f*/23	5·3
No.	...	...	...
No.	...	...	...

10. Angle of cone of illumination with largest stop = 68°, giving a circular image on the plate of† 13·2 inches diameter.
Angle of cone outside which the aperture begins to be eclipsed, with stop C.I. No. 1/1·38, = 20°, giving a circular image on the plate of 4·0 inches diameter.
Diagonal of the plate = 10·7 inches, requiring a field of 51°.
Stop C.I. No. 5·3 is the largest stop of which the whole opening can be seen from the whole of the plate.
11. Principal focal length, † = 11·28 inches. Back focus, or length from the principal focus to the nearest point on the surface of the lenses, = 10·4 inches.
12. Curvature of the field, or of the principal focus surface. After focussing † the plate at its centre, movement necessary to bring it into focus for an image 1·5 inches from its centre = 0·02 inches.

Ditto for an object 3 inches from the centre = 0·04 inches.
" 4·5 " = 0·10 "
" 5 " = 0·15 "

13. Definition at the centre with the largest stop, *excellent*. C.I. stop No. 1·35 gives *good* definition over the whole of a 6·5-inch by 8·5-inch plate.
14. Distortion. Deflection or sag in the image of a straight line which, if there were no distortion, would run from corner to corner along the longest side of a 6·5-inch by 8·5-inch plate = + 0·01 inch.‡
15. Achromatism. After focussing† in the centre of the field in white light, the movement necessary to bring the plate into focus in blue light (dominant wave length, 4420), = + 0.01 inch § Ditto in red light (dominant wave-length, 6250) = − 0·01 inch.§
16. Astigmatism. Approximate diameter of disc of diffusion† in the image of a point, with C.I. stop No. —— at —— inches from the centre of the plate = 0·—— inch.
17. Illumination of the field. The figures indicate the relative intensity at different parts of the plate.†

With C.I. stop No. 1/1·38.		With stop No. 5·3.	
At the centre	100 :	Ditto	100
At 3 inches from the centre	67 :	Ditto	82
At 5·35 " "	28 :	Ditto	66

General Remark.—An excellent medium angle rapid objective, practically free from distortion.—W. Hugo, *Observer*.
Date of issue G. M. Whipple, *Superintendent*.
Leonard Darwin, *Major, late Royal Engineers*.

(*To be continued*.)

THE GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC EXHIBITION.

The members of this flourishing Association have again brought together in their own rooms at 180, West Regent-street, a large and interesting collection of photographs, the work being confined to members only.

The Exhibition comprises both non-competitive and competitive classes. The latter are all well filled, and in the classes for landscape, transparencies, and enlargements, the work shown is of a high order, the weakest class, as usual with most amateur exhibitions, being portraiture.

The arduous duties of judging the collection was intrusted to Messrs. Robb, Young, and Annan, and with the exception of their decisions in the Landscape Class, about which there seems to be a pretty widespread opinion that a decided error has been committed, their decisions are satisfactory.

In the Landscape Class Mr. John Morison, jun., stands out pre-eminently with an exceedingly fine exhibit of six 12 × 10 pictures in sepia platinotype.

This year Mr. Morison has visited that charming spot, the Trossachs, and has succeeded in bringing home some exquisite results. He takes the silver medal for frame No. 20, which include three views, *Loch Achray and Ben Venue, Loch Katrine and Ben Venue, Achray Church and Ben Venue*. The centre picture is a gem, and is generally considered to be far and away the best picture in the Exhibition.

Other prominent exhibits of great merit in this Class are those of Mr. J. C. Oliver, Mr. Stuart Smith, and Mr. Hugh Reid. In the opinion of most members, the bronze medal ought to have gone to one of the above three, and not, as the Judges have seen fit to ticket, No. 5, a collection of three half-plate landscapes from the camera of Mr. Adam G. Brown.

Turning from the Landscape Class to the Instantaneous, Mr. Snell Anderson again takes the silver medal with a charming collection of marine views printed in platinotype. Mr. Anderson's individuality is in evidence in the three little gems which are to be seen in frame No. 31. The bronze medal goes to Mr. A. Lindsay Miller.

Perhaps the most interesting class in the Exhibition is the lantern slide exhibit, in which we notice there are about twelve exhibitors, all being of great merit, and the Judges must have had some trouble to distinguish among so much that is excellent. The first medal goes to Mr. Arch Watson, and Mr. A. Lindsay Miller secures the bronze medal. In this class Mr. Snell Anderson shows a very charming collection of marine views.

In the Enlargement Class Mr. Arch Watson secures the silver medal for the same set of pictures that he exhibits in the Lantern Slide Class.

The Portraiture is the worst class in the Exhibition, and, although numerous, does not contain a single exhibit of special merit.

The space of the entire walls and pillars of the large room of the Association is completely filled, and, on the whole, the work shows a distinct advance on previous years.

Profiting by the success which attended the recent International Photographic Exhibition in Glasgow, the funds of the Association were largely augmented by the substantial surplus. The Council have been enabled to provide increased facilities in the way of comfort and utility in the fitting up of these rooms, which are now, perhaps, unapproached by any other Association in the kingdom.

At the first meeting of the members for the ensuing season no less than twenty-six new members were added to the roll, and the council are acting in a liberal spirit towards the large number of members who now make up the Association.

Quite recently the dark room has been entirely refurnished, and now it offers facilities to the members, which we question if any other society can offer. By an arrangement of the House Committee members are not only supplied with every necessary utensil for the development of the tiny quarter-plate up to an enormous enlargement, but they have likewise always at their command a supply of the ordinary chemicals required in development; the duty of the House Committee being to see that such are always kept in stock for the use of the members.

We noticed an enormous overhead development lamp that must be of great use when working on large subjects—a lamp that any professional must envy.

We understand the judges could not agree as to the best picture in the room, and so they awarded two silver medals in the Landscape Class, the second going to Mr. John W. Eadie. Altogether, the Glasgow and West of Scotland Amateur Association is flourishing.

"NORTH HOLLAND IN GLASGOW."

Messrs. Annan have very fitly inaugurated the opening of their new premises in Sauchiehall-street, by an exhibition which is somewhat out of the ordinary run of exhibitions, and one which, in many respects, may be considered unique. The results of a joint holiday ramble in North Holland are here gathered together, one artist giving his impressions of that quaint country by a series of etchings, while the other gives his through the medium of the camera. Mr. D. Y. Cameron, the well-known etcher, is responsible for the former, while the photographs are the work of Mr. J. Craig Annan. The collection contains some seventy-five examples, etchings and photographs being grouped alongside of each other. Mr. Annan worked chiefly with the hand camera, quarter-plate size, and the pictures thus obtained have been reproduced (enlarged) in

* C.I.—International Congress System.
† The lens is focussed on a very distant object.
‡ The sag or sagitta here given is considered positive if the curve is convex towards the centre of the plate.
§ Positive if movement towards the lens, negative if away from it.
‖ The lens is supposed to be perfect in other respects.
Note.—The following is the scale of terms used: excellent, good, fair, indifferent, bad.

autotype. It may safely be said that this is the first occasion on which photographs and etchings have been brought into such close relationship, and a very good opportunity is thus afforded how far photography can compete, if such a term can be applied.

After a careful inspection of the collection, the conclusion is forced upon one that photography, at all events, can hold its own. It goes without saying that artistic work in photography can only be produced by one having that innate feeling which suggests how and when a genuine picture is to be secured. The works shown by Mr. Annan abundantly testify to the fact that he possesses this faculty, and that in no ordinary degree.

Where all are so good it is difficult to single out specimens, but *A Utrecht Pastoral* (38), a truly characteristic Dutch landscape, is particularly fine. The high trees on one side of the picture, the sheep trotting along the road, the canal, and the grand masses of cloud all go to form a most pleasing whole, free from that hardness which is so often seen in photography. *Fishers and Wives* (40), an animated shore scene, where the disposition of the various baskets has helped the artist to no small extent. Another picture well worthy of notice is *Labour-Monday* (42). Here we have a phase of peasant life treated after the manner of Millet—three labourers hoeing in a field. *On the Nord Holland Kanaal* (12), the effect of swirling water in the foreground has been most happily rendered. Another curious effect of broken or rather disturbed water is to be found in the picture, *Reflections on the Rokin Gracht* (17). Dutch dogcarts, groups of peasants, scenes in the various markets, all the different phases of outdoor Dutch life have been faithfully and artistically portrayed by Mr. Annan.

A word remains to be said regarding the framing. Several of the pictures square in size have been surrounded by a square, flat, broad frame, the whole carrying out the idea of a Dutch tile. If the picture is printed in Bartolozzi red, a frame of material resembling ivory surrounds it. The variety of the tones employed in the reproduction of the pictures lends additional interest to this most interesting cabinet collection; greens, browns, reds, are all intermingled, so that there is a complete freedom from anything like monotony. *Near Ijminden* (54), a view on the beach has been printed in autotype, and the grey-green tint employed is particularly well adapted to the subject depicted. In addition to the pictures on the walls, a large series of photographs printed in platinotype are to be found lying in an album on one of the tables. The exhibition reflects great credit on the originators, and is well worthy of a visit from all interested either in photography or in art. A neat and artistic catalogue has been compiled for the benefit of the visitor.

TWO CONVENTIONS.

The British Convention, or, as its organizers prefer to call it, "The Photographic Convention of the United Kingdom," meeting in Edinburgh, has been, says "Watchman" in the *Beacon*, according to the unanimous opinion of the British press, not only the most successful of the seven, but a thorough success in every way. Comparisons, according to Mrs. Partington, are odorous, but duty will not let us overlook one question. Why is it that the great success of what should be the great American gathering, the Photographers' Association of America Convention, is generally confined to preliminary boasting of what will be, while that of its British sister, or more correctly, daughter, is realised as an actual fact? The British has been a great success in everything that goes to make a successful Convention at an expenditure of less than $200, while the Photographers' Association of America, at a cost of about twice that number of thousands, has been—well, not a great success.

Is it not just possible that the difference arises from the different ways in which the Executive of each goes to work? In the British there are no paid officers, and as all the work is a labour of love, every member puts his shoulder to the wheel as if its motion depended on his efforts. The authorities in the cities in which the meetings are held, recognising the non-commercial nature of the Convention, and appreciating the influence of photography as an educational agent, give the free use of the most suitable buildings under their charge; there are no medals or awards to produce heartburnings and disappointments, and while the professional and amateur meet on equal terms, or rather the distinction is altogether ignored, there is absolutely no flavour of the "shop" in all the proceedings.

Monday, October 31, is the last day for receiving exhibits (which must be accompanied by entry forms, if not previously sent) for the Exhibition of the Leytonstone Camera Club at the Masonic Hall, Leytonstone, November 10, 11, and 12. Lady Brooke will open the Exhibition at six o'clock on Thursday, the 10th inst.

,, 4	Maidstone	"The Palace," Maidstone.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

October 25,—Mr. Thomas R. Dallmeyer in the chair.

M. Boissonas' Tele-photographic Picture of Mont Blanc.

The Chairman referred to a tele-photograph of Mont Blanc by M. Boissonas, which he had brought with him, and which he asked members to compare with that in the Photographic Society's Exhibition, and they would find in the second picture (which was taken at a distance of forty-four miles) much finer definition. The weather was windy when the Exhibition picture was taken. In all tele-photography it was preferable to have calm weather, and in this respect the second photograph was taken under much more favourable circumstances than the first and was much more clearly defined. When using the tele-photographic lens any slight tremor made the nodal point move a good deal more than it would under ordinary circumstances, when using a lens in which the nodal point was within the lens system itself.

The Hon. Secretary exhibited and explained Messrs. Watson's new Alpha hand camera for use with double backs. The front let down, being supported

by a strut pressed into a notch—it was then drawn out and clamped. The parts were interchangeable.

Architectural Photography.

In opening this subject, Mr. F. P. Cembrano, jun., said it might be subdivided into three parts—Apparatus, process, and subject. Dealing with the first, he thought the tripod should be one with sliding legs, and rigid. He did not think it was a good policy to take the picture from a very high point of view. Photographs taken from a height of ten or twelve feet did not give one a representation of the subject as one was used to see it. The best point of view was the same height as one's eyes. The tripod was liable to slip about, and various devices had been suggested—such as corks—to prevent that. He thought Mr. A. L. Henderson's idea of struts fixed to the tripod a great convenience for this purpose. The best camera for use was one with a square bellows; the ordinary conical bellows was difficult to manage when used with short-focus lenses. Another point with regard to the camera was to have the back perfectly square, so that one could be able to draw the shutter from either the right, the top, the left, or the bottom. As to the swing front, he did not know how far it was essential or useful, but he himself seldom found any use for it. He preferred to tilt the camera and swing the back. For dark interiors, it was useful to oil the screen of the camera, which helped one a good deal in focussing. Some of his Spanish interiors were so dark that he could not focus even in that way, so that he had to ask somebody to hold up a light for him. As to lenses, he had used both Dallmeyer's and Ross' symmetricals with satisfactory results, and no doubt the newer lenses such as Zeiss, the Concentric, &c., would do just as well. A level to place on the top of the camera so that one could see the spirit horizontally, was essential in photographing interiors, especially when the buildings were not upright. Backed plates were admirable for interiors, although for ordinary work a plate that was rapid and that had plenty of emulsion on it would help one a good deal against halation.

A number of slides, illustrating points in Mr. Cembrano's address, were then projected on the screen. In reference to the first of these—a church interior at Bath—he said that having given about half the exposure required—twenty-eight minutes with *f*-45—he was told that the church would be required for a service; he then altered the diaphragm to *f*-16, and gave another fifteen minutes. Contrary to what might have been expected, there was no doubling of the image. Continuing, he said architectural photography might be divided into several branches—for instance, photography for architects in the rendering of small details, of which they saw plenty of illustrations and sets. He would point out that, where possible, objects near the camera should be avoided, especially with regard to interiors of private houses. Very often such pictures would be improved by moving a chair or a table which was quite close. Conspicuous things, indeed, should be avoided when using short-focus lenses.

Development of Interiors.

One often got strong contrasts, especially when photographing in the south, where buildings painted white were so abundant. Besides the importance of giving full exposure, one had to be very careful in the development. He found himself, when photographing in the south of Spain, that the only way to obtain a good result in the deepest shadows, as well as to get printing density in the highest lights, was to develop with a brush, starting with a weak developer to get the image out, and, when once it showed, washing the plate thoroughly, strengthening the developer, and with the brush developing up such parts as the dark parts of a ceiling, and, generally, the detail in the shadows. In the case of a negative where all the light the subject received came from the front, development in the ordinary way would be useless; in the way he had mentioned, no detail in the high lights would be lost. For such a picture, with an exterior view, one second, with *f*-32, would suffice for the exterior only; the interior, with the exterior showing, had half an hour. Where the light came in through two doors, he had seen an architect cover up one of them with black velvet, expose for the interior, take down the velvet, and then expose for a few seconds for the exterior view. In taking interiors, Mr. Cembrano continued, it gave pictorial effect to the picture, and gave better perspective, or better ideas of depth, if one managed to take the picture facing the light—having a window or door at the end of the picture. Of this effect he showed several examples from his Spanish Alhambra series. In exteriors, where possible, one should endeavour to wait for the sun to break up the shadows. Figures, again, often helped in architectural photography; so that what would otherwise be nothing but an uninteresting photograph, except to architects or archæologists, might be made quite pictorial. This point he also illustrated, and, going on to remark that architectural studies might also be improved by the addition of clouds, showed a slide of Salisbury Cathedral in proof thereof. In conclusion, he indicated the suitability of the optical lantern for showing architectural photographs, a large screen showing off the slides to better advantage than a small one. Thus, an amateur could always use a quarter-plate camera, and get the best results, trusting to the optical lantern for showing them on a large scale.

Mr. Chapman Jones showed examples of distortion by tilting the plate, and the partial cure by copying, the negative or the plate being then inclined. He had photographed a series of squares on a sloping plate, and pointed out that one not only got converging perpendiculars, but a larger and smaller scale of graduation. The convergence of perpendiculars might be cured by sloping the plate in the camera, but one effect of the distortion would still be left, due to the alteration in the scale of the squares, the image being lengthened in the direction of the tilt. If the distorted negative alone were tilted, and the plate in the camera kept vertical, the opposite effect would result, the image being shortened vertically. Mr. Jones observed that it had never been stated exactly how one could get over the difficulty.

Mr. T. Sebastian Davis said, with regard to Mr. Cembrano's method of development, there was a point of universal applicability. In taking ordinary landscape subjects—or rather the majority, to which his observations referred—they obtained a considerable portion of the parts which could not be brought out to the best advantage by uniform development, the lighter portions of the picture becoming too intense before they could bring out all the details in the shadows, more especially foliage and other dark parts of the picture. He himself had suggested Mr. Cembrano's method of development, in the first instance, for bringing out, as far as possible, the whole of the details of the picture before intensifying the other portions. They obtained a far wider range by washing away the developer, and then redeveloping those portions which are the darkests parts by the application of the developer with a soft brush to those particular portions.

Mr. Cembrano said he applied the method to landscape photography, especially where he wanted to secure the sky—developing the sky first, before anything else on the plate, and bringing out the rest with normal development. As to gauging what was going on during development (a point referred to by Mr. Davis), a thickly coated plate took a long time before the image got through, and was obliterated in brush development. He had never developed a plate altogether black. For architectural subjects and interiors, he advised a developer giving blue images as far preferable to one with which hardness might be got. He used pyro-ammonia, with plenty of sulphite. In some cases he washed as many as ten or twelve times, his object being to avoid markings. He would like to ask the Chairman whether there was any means of obviating the distortion which was inevitable in taking most architectural subjects—a high building, or an interior, where one had to tilt the camera and swing the back, and in doing so shortened the image and started distortion.

The Chairman, in reference to Mr. Cembrano's suggestion that the camera should not be raised above the level of the eye, would have thought that in architectural work it would not have mattered how high the camera was placed. It was certainly impossible to obviate exaggerated perspective which comes in tilting the camera, and having near foregrounds and distance. It depended upon true monocular perspective, which was an absolute science, certain laws being obeyed which could not be got away from. As regards architectural lantern slides, he thought such slides on a big screen were much more satisfactory than pictures of the same subject from a near point of view. By the employment of long-focus lenses such as are used in tele-photography, they were able to maintain the sensuous impression of the perspective, whereas the same picture if taken from a near point of view, would produce strained appearances. Most lantern slides seemed to lose a good deal of this forced appearance in projection.

After a vote of thanks to Mr. Cembrano the meeting adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

October 20,—Mr. C. H. Cooke in the chair.

Mr. C. G. Norton passed round several old and recent prints from the wet-plate negatives he showed at a previous meeting, and among them a print made in 1851 from a paper negative.

Amidol.

In the course of a short discussion on this subject, Mr. J. A. Sinclair observed that amidol might be used with rodinal without disastrous effects.

Mr. P. Everitt found that carbonate of soda accelerated the action of amidol.

Mr. E. W. Parfitt observed that he got more detail in a negative by developing with pyro-soda, rinsing it off, and then continuing development with amidol.

The "Frena" Hand Camera.

Mr. Bynoe exhibited and explained the principles of Messrs. Beck's "Frena" hand camera, exhibiting enlargements from negatives made therewith. He also showed the "Bynoe" printing frame, which he incidentally observed had been introduced for printing the "Frena" film negatives.

Mr. J. Weir Brown thought it a disadvantage that the lens of the "Frena" only worked at *f*-11, and suggested that other stops should be provided.

The decision of a lantern-slide competition and a miscellaneous display of slides concluded the meeting.

North London Photographic Society.—October 18, 1892, Mr. J. Traill Taylor in the chair.—Copies of Messrs. Catlett & Neall's new monthly paper, *Dry Plates*, were distributed. Mr. Mackie showed an advance copy of the Ilford *Year Book*, which was much appreciated. Nominations were received for election of Council at the Annual Meeting to be held on November 1. The Chairman then brought before the members a series of notes on the reproduction of photographs by means of printing ink, in which he dealt with the various photo-mechanical processes from the time of Nicephore St. Niepce to the present, the processes being not only described, but illustrated by specimens. A cordial vote of thanks to Mr. Taylor concluded the meeting.

North Middlesex Photographic Society.—October 24.—The first Members' Lantern Evening of the season was held. The President (Mr. J. W. Marchant) was in the chair, and about 120 members and friends were present. Messrs. Ainsley, Beadle, Chang, Fox, Gregory, Jones, Marchant, Mummery, Plunkett, Smith, Taylor, Littenoor, Wall, and Wynne contributed slides, and Mr. R. F. Wynne manipulated the lantern. The slides were of the usual varied character, some of the sets being of great beauty, and, as a whole, showed a marked improvement over last year's work. In nearly all instances much attention had been given to securing atmospheric effects, and in the majority with considerable success. The glittering black and white slides, with points of light spotted all over them, of early days, were conspicuous by their absence. The next meeting will be held on November 14, when Mr. J. Traill Taylor will address the Society on *Photographic Optics*. Visitors will be welcome.

Holborn Camera Club.—October 21, Mr. J. Havery in the chair.—Mr. E. Benest gave a lecture and demonstration on *Simple Chemical Analysis for Photographers* (see page 694). He experimented with various chemicals he had brought with him, and gave to the members present quite an instructive and unique demonstration. On Saturday last the Club entertained the members of the Holborn Cycling Club by giving a lantern show of slides made from negatives taken at the Southern Cyclists' camp, held at Dorking in August this year.

Lantern Society.—October 24.—Mr. Taylor exhibited an improved form of Lawson's saturator, which gave a very brilliant light. Mr. Askew exhibited his portable lantern and stand, of ingenious construction, and capable of being carried on a bicycle. It is made by Messrs. Newton. The Hon. Secretary then showed a lantern of a novel description, which he had designed for his own use. In its construction aluminium was used wherever practicable. Instead of the metal-lined mahogany body, there was a cloth curtain lined with asbestos; the condenser mounted in aluminium was held between two thin plates of the same metal; and the slide carrier was held rigidly in position by means of an aluminium plate and two screws. The lens was mounted in a plain aluminium tube, and was carried by a small saddle, moving along the front board by means of a rack and pinion, and connected to the lantern body by a small camera bellows. For packing away the whole thing folded up, and together with all the necessary fittings and two regulators stowed away in a box $18 \times 12 \times 5\frac{1}{2}$ in. The total weight, including the box and regulators, was about twenty-one pounds, the corresponding weight of the lantern which it has superseded being thirty-eight pounds. The space for the jet was practically the same as in an ordinary lantern, so that any jet, or an oil lamp, could be used with it

Hackney Photographic Society.—October 18, Mr. W. P. Dando in the chair.—Messrs. Cross, Green, and Dr. Vere-Nichol were nominated for membership. Work was shown by Messrs. Gosling, Puttick, and Beckett (portraits of the Exhibition Committee), S. J. Beckett, Funstough. Mr. S. H. Barton then gave a short paper with illustrations on *Portraiture without a Studio*. He had been fairly successful outdoors in taking portraits, and his method was to take them between two walls. He said it was advisable to not have too much top light. Portraits should be soft, and a formula he recommended to obtain softness was an eikonogen one, given by Mr. Chapman-Jones. The Society's blackboard was then requisitioned, and the Hon. Secretary proceeded to draw a design he had made for taking portraits in the open. It consisted of four uprights, after the fashion of an ordinary clothes-horse, and the lighting was subdued as required at top and sides by various kinds of calicoes, &c. Mr. Gosling had used a roll of Lancaster window-blind as a background and shield from the top light. The Chairman had found the ordinary brown paper used for putting under carpets of service. The Hon. Secretary said he had obtained good results with this. Mr. Beckett, in answer to various questions put to him, said he would have a fair amount of top light and a high shield at the back and side. As far as retouching was concerned, he advised it in a general way, but the likeness ought never to be sacrificed to the retouching. Mr. Gosling asked how to reduce a small dense part of a negative. The Chairman said he would use methylated spirit one part, and water two parts, gently rubbing in solution with cotton-wool. Mr. Beckett said he would use a knife, but with great care. The Hon. Secretary announced that the next meeting (Tuesday) would be a Flashlight Evening.

People's Palace Photographic Club.—October 19, Annual General Meeting.—The following are the officers for the ensuing year:—*President:* The Chairman of the Drapers' Company Institute.—*Vice-Presidents:* Messrs. C. W. Gamble, J. Osborn, and G. Hatton.—*Committee:* Messrs. R. Beckett, W. Barrett, G. Bolton, G. Clarke, G. Kendall, T. Lawday, G. Patten, and W. K. Walker.—*Hon. Secretary* and *Treasurer:* Mr. S. J. Beckett, The Grove, Hackney, N.E. Photographers (amateur and professional) desirous of becoming members are asked to write the Hon. Secretary for particulars.

Leytonstone Camera Club.—October 22, Dr. W. P. Turner (President) in the chair.—Mr. A. P. Wire gave a lecturette on *Stereoscopic Photography with a Single Camera*. Mr. Wire explained, very lucidly, the principles involved in the construction of the stereoscope, its lenses and pictures. A stereoscope was exhibited that was made by the lecturer, and made in such a way that the lenses could be taken out for examination. In explaining on what principles the pictures were made, Mr. Wire showed some line drawings made by hand, in which the stereoscopic principle was adopted, and which in the stereoscops showed the well-known solidity. Next were shown some photographs of still life—shells and vases of flowers—which had been made by the lecturer. The camera was fixed, and the object to be taken placed on a small turntable. Taking one view, and then moving the object and table slightly round, a second view was taken. In this way, by using ordinary quarter-plates, the two necessary views were taken, and capital stereo-photographs made. Mr. Wire having shown that his plan was only adapted to still life, Dr. Turner "took up the parable," showing a handsome little stereo-camera for outdoor work, with single lens and case-board so arranged that the two pictures can be taken on a stereoscopic plate by moving the camera along the case. A discussion followed, in which Messrs. Watson Brown, M.A., F. Wates, W. G. Roberts, and others took part.

Putney Photographic Society.—October 17, Rev. L. Macdona in the chair, the subject being, *How to Make a Lantern Slide*, by Mr. S. Herbert Fry.—Mr. Fry commenced by pointing out what qualities were necessary in good lantern plates, and in what particulars their treatment and the result desired differed from negative plates. The essential requirements of a good slide were that in some part of it there should be absolutely clear glass, and that the darkest shadows should be transparent. In order to secure these results a fairly correct exposure was necessary, and forcing of development should on no account be attempted; he therefore recommended a standard developer which, by experience, had been found to work well with the particular brand of plates in use, and that no modification of this should be tried in order to compensate for over or under-exposure. The use of such a standard developer naturally required a more correct exposure, relatively, than that necessary for a negative plate, where a modification of the developer was permissible; but, as the exposure of the lantern plate was under more perfect control, there would in practice be found little difficulty in giving the right time. The slides could be made in two ways, viz., by contact, or in the camera. Contact printing was, on the whole, best done by artificial light, and in the camera by daylight. Mr. Fry showed a printing frame in which a slide could be made by contact from any suitable part of a larger negative; he claimed no special advantage for the particular form of frame, but it was obvious that a contrivance of the kind was a convenience, not to say necessity, in successful working, as it was of importance that the edges of the lantern plate, *i.e.*, the thickness of the glass, should be protected against stray light; the omission of such protection was a frequent source of fog near the edges. With regard to the illuminant used during exposure, it was no doubt possible as a *tour de force* to use a wax vesta, but Mr. Fry said he would assume that the members generally worked with a paraffin lamp or gas-burner, and these would perhaps be found the most convenient in ordinary work. Weak negatives were best printed from by a weak light, or at a considerable distance from a powerful one, whereas plucky or dense negatives would give the best results when printed close to a good light. The time of exposure would, of course, vary with the character of the negative, but the correct exposure could be readily determined in the following manner:—Divide the plate approximately into, say, five strips, then shield four-fifths, and expose the one-fifth 10 seconds, the shield being then moved so as to screen only three-fifths, and kept in this position another 10 seconds, and so on until the whole of the plate has been exposed; one-fifth will then have been exposed 10, the next 20, 30, 40, and 50 seconds respectively. On developing this trial plate in the standard developer, it would at once be apparent which part of it had received the correct exposure. When the correct exposure has been once ascertained, it should be noted on the negative, together with the nature of the light and the distance from it, for future reference; the negative envelopes now commonly in use lend themselves conveniently for notes of this kind as well as for storage. The exposure being correct, the development in the standard developer would present no difficulties, it being only necessary to watch progress, and to take the plate out when of sufficient density. On the subject of exposure in the camera, Mr. Fry said this could be done either in daylight or by artificial light. When daylight was used, the negative could conveniently be placed against the window, and the camera pointed at it, and focussed to the desired size, care being taken that no buildings, chimneys, trees, &c., should appear behind the negative, as they would, of course, be reproduced on the lantern plate. It would not be necessary to exclude daylight from the room, but direct rays of light must be prevented from entering the lens, and this could be efficiently done by placing a piece of brown paper, with a hole cut in the centre for the negative, against the window, the paper being of such a size as to cover the cone of light entering the lens; no further covering between the negative and lens is necessary. Daylight being very variable, no rule as to the length of exposure could be laid down; generally a small stop should, by preference, be used in a fair light, so that the exposure might be well under control. As regards artificial light, the chief difficulty was to obtain even illumination of the negative. Mr. Fry said he had used, with satisfactory results, the following arrangement:—The negative is placed at the end of a suitable box or frame opposite the lens, which may be mounted in the usual way on an ordinary camera, and the lantern plate exposed in a double slide, exactly as when taking a negative; special apparatus for making lantern slides by reduction is frequently used, but, as will be seen, is no necessity. The illumination of the negative is obtained as follows:—A piece of white opal, white paper, or a whitewashed board, is placed at some little distance behind the negative and parallel with it. On *each* side, between the negative and reflector, is placed a lamp, or gaslight, or other convenient illuminant; the two lights should be placed near the negative, and as close together as possible, but without allowing any part of their images to enter the field of the lens. It has been found that by this system of using reflected light about forty per cent. of the total is utilised, and that the illumination is very even. In order to obtain the best results as large a stop as possible, consistent with the covering power of the lens, should be used. As an example, it may be stated that with a good light and an average negative, working the lens at *f*-16, an exposure of four minutes will be about right. One of the advantages of the reduction method in the camera is that, by the careful use of the swing back, divergent and convergent lines in the negative may be rectified on the slide. On the subject of printing in clouds, Mr. Fry said that the easiest method was to print them on a separate plate, and use this as a cover plate, due note being taken that when so placed the direction of the light would be reversed, and that, therefore, it was necessary to print from a cloud negative with the light coming from the right in order to suit a view which is lighted from the left, and *vice versâ*. The cloud print should be given a comparatively short exposure, and should not be developed far, otherwise there was danger of loss of transparency. During the lecture Mr. Fry illustrated his points by practical demonstration, exposing, developing, and fixing prints of views and clouds.

South London Photographic Society.—October 17, the President (Mr. F. W. Edwards) in the chair.—Mr. Arthur C. Baldwin opened *A Chat on the Eastman Products*, and dealt with the various methods for producing the stripping films formerly sold by the Eastman Company, which ultimately led to the manufacture of the rollable film, as now manufactured. The method of using the roll-holders was now explained, and specimens shown. The "Sol'o" paper was then dealt with, and explanation was given as to the means to be adopted for producing a variety of tones. The formula for the borax bath (blue tones), and the combined toning and fixing bath (warm tones) were given with the paper when purchased. For rich velvety black tones the following was recommended:—Phosphate of soda, 100 grains; chloride of gold, 5 grains; water, 40 ounces. The addition of a pinch of aluminium chloride to the ordinary alum bath materially assisted in the hardening of the gelatine film. Potash alum must always be used, as ammonia alum does not form in this case a good substitute. The combined bath was so simple "that a child can make and use it, is delightfully certain in its action, and is practically permanent." The proceedings terminated with the toning of several prints by the different baths, to show the tones obtainable. Attendance, forty.

West Surrey Photographic Society.—Usual fortnightly meeting at headquarters, the Public Library, Lavender-hill, Clapham Junction. Mr. Winsford in the chair.—The subject of the evening was a demonstration, by Mr. George H. James, of the *Carbon Printing Process*. Mr. James went fully into all the details of both the single and double transfer processes, illustrating his remarks by prints from some of his very fine snap-shot negatives. Mr. James, after having described the safe-edge necessary in carbon printing, and various forms of actinometer to gauge the depth of printing by, went on to describe the development of the image. He said that one of the peculiarities of this

process is that the development takes place from the back, this being due to the fact that the parts of the sensitive, bichromated gelatine acted upon by the light, are rendered insoluble in water, and, as the light never did penetrate right through to the surface of the paper, there was always between the insoluble gelatine and the paper a layer of soluble gelatine, which was dissolved out in developing; hence the necessity of fixing the print upon the temporary or permanent support before development. A large number of prints, made by the Woodbury Company, were passed round for inspection.

Brixton and Clapham Camera Club.—October 18, Mr. James W. Coade (Vice-President) in the chair.—The CHAIRMAN first referred to the Club Exhibition to be held on the 17th, 18th, and 19th of next month, and begged members to put their shoulders to the wheel, and to make the Exhibition a great success; he reminded them that the last day for receiving exhibits was the 8th proximo. Subsequently Mr. F. W. KENT gave a few interesting remarks on *Bromide Paper and Lantern Slides*, and, by making several prints, showed the different results which could be obtained by varying the exposure, distance from the light, and the developer. The paper used was Ilford Slow, and the developer ferrous oxalate. Mr. Kent also made some lantern slides from half-plate negatives in a reducing camera of his own construction.

North Surrey Photographic Society.—October 18.—Mr. FITZPAYNE read a paper and gave a demonstration of *The Method of Development of the New Cold-bath Platinotype Paper*. He commenced by stating that the paper was more convenient to manipulate than the hot-bath paper; that the results achieved were superior; that the film was not susceptible to abrasion; and that the liability to scald the fingers was, of course, entirely absent; and then proceeded to practically prove his assertions by developing several prints, during which operation the remarkable control which could be exercised over the action of the developer was very apparent. He explained the necessity for printing the paper until the whole of the details were out, in fact, that printing should be carried as far as possible without solarisation, but stated that, should this stage be reached, it was possible to print out with the paper, and then, of course, no development was necessary, the print only requiring to be fixed in the hydrochloric-acid bath. He drew attention to the necessity of using a much weaker developer than was required for the hot-bath paper, and recommended the use of the Platinotype Company's "D" salts in the proportion of a quarter of a pound to forty-eight ounces of water, and showed how, when mixed with an equal quantity of glycerine, the operation of development was most simply performed with a brush, the print being stretched on a glass slab or on the bottom of a dish. After developing a print, with the most excellent results, Mr. Fitzpayne explained the process of toning or, to describe it more accurately, of painting the platinum image with uranium, for the formula of which he referred the members to his memorandum on the subject in the *Camera Club Journal* for October. Numerous prints that had received this treatment were handed round for inspection, some showing the different shades that could be obtained—from light brown to a very deep red, and some the bad effect of not entirely eliminating the iron from the print before toning. In reply to a member, Mr. Fitzpayne explained why "painting" was an apter description of his process than "toning," as the whole resulting colour could be easily removed by immersing the print in a weak solution of ammonia.

Blackheath Camera Club.—October 4, first Annual General Meeting, Dr. Ernest Clarke, M.D., B.Sc., in the chair.—The officers for the Session of 1892-93 were elected as follows:—*President:* Mr. W. H. M. Christie, M.A., F.R.S., F.R.A.S. (Astronomer Royal).—*Vice-Presidents:* Dr. Ernest Clarke, M.D., B.Sc., and Mr. J. T. Field, L.Mus., I.C.L.—*Council:* Revs. W. P. McDonald, M.A., and W. K. Soames, M.A., F.R.A.S.; Messrs. Edmund Dashwood, M.R.C.S.; W. Claude Johnson, M.I.C.E., F.R.A.S.; Samuel E. Phillips; George Vesper, and E. J. C. Wiseman.—*Hon. Curator:* Mr. W. Farrington.—*Hon. Treasurer:* Mr. A. W. Young.—*Hon. Secretaries:* Messrs. T. R. Earle, The Cottage, Handen-road, Lee, S.E., and C. W. Piper, 46, Shooters' Hill-road, Blackheath, S.E. The report for the last Session, which was unanimously adopted, shows a good record of work done in the way of lectures, demonstrations, and summer excursions, while the balance-sheet shows that the Club is in a very satisfactory financial position, considering that it is only just entering the second year of its existence. The Council hope to be able in a short time to provide a dark room for the use of members, to many of whom it will doubtless be of great service. The first ordinary meeting of the present Session was held at the Art Club, Blackheath, on October 10, the Rev. J. H. S. Taylor, B.A., being in the chair. Dr. Ernest Clarke (Vice-President) gave a lecture on *The Eye as a Camera*, illustrated by lantern slides specially prepared for the occasion, and also by models. The lecturer described in detail the complicated structure of the human eye, pointing out the manner in which the various parts are reproduced in the camera. He explained that the lens of the eye can be separated into three distinct lenses—two divergent menisci with a double convex between—thus bearing a striking analogy to a photographic lens. The iris corresponds to the diaphragm or stops, but automatically adjusts itself, the aperture becoming smaller as the light increases, and larger as the light diminishes; it is in front of the lens, and both are protected by the cornea, which is simply a transparent cover to prevent dust, &c., from interfering with the delicate mechanism of the iris and lens. The retina corresponds to the sensitive plate, and consists of the interior coating of the back of the eye, which, under the microscope, is seen to be of a very complicated structure. From this sensitive surface the sensations of light and colour are carried by the optic nerve to the brain. The retina differs from the sensitive plate in having a curved surface, which at all parts is equidistant from the lens, whereas the photographic plate has, of necessity, a plane surface, the centre being nearer the lens than any other portion, and the edges being at a greater distance; this is the cause of what is known as curvature of the field—a defect which, of course, does not exist in the eye. The most remarkable difference between the eye and the camera is in the manner of focussing; this in the camera is accomplished by moving the lens either further from or nearer to the plate, but in the eye the lens itself is altered by a series of muscles, arranged so as to act upon it from all sides, which make it more or less convex, as required. In the normal eye, focussing is only necessary for objects within a distance of about twenty feet, for anything beyond that distance the eye is practically a fixed-focus camera. The whole interior of the eye is filled with a semifluid, transparent matter, and the retina is impregnated with a black pigment to prevent the reflection of light within the eye; the interior of a camera is, of course, blacked for the same reason.

Bournemouth Society of Natural Science (Photographic Section).—October 19, Inaugural Meeting of the winter session of this Section. The President (Rev. J. R. Husband, M.A.) took the chair.—A short address was delivered by the PRESIDENT, who referred to the work accomplished during the summer, also urging the members to renewed exertions in the direction of artistic photography as well as to excel in the working of the various processes. The President also gave some notes on the *New Cold Bath Platinotype Printing Paper*, during the reading of which the chair was occupied by Dr. H. Nankivell, one of the Vice-Presidents. Two prints were developed and fixed by the new process, and the simplicity with which the paper was worked recommended itself to all present. An album of interesting views on this paper was shown, and the President also announced his intention to give a prize to be competed for by the members of the Society who were beginners. Some notes on Ilford Printing-out Paper were also given by Mr. P. H. PRICE. The various results to be obtained by different toning baths, also the difficulties that could be overcome in numerous ways during the operation of printing and toning, &c., were well illustrated by some nicely finished views which were handed round for inspection.

Brechin Photographic Association.—October 19, Mr. H. Braid (Vice-President) in the chair.—The SECRETARY, as delegate to the Photographic Convention, gave a short report of the proceedings and exhibits, and exhibited the "Developan" and Beck's new metal printing frame. The developan having only come to hand that morning, it had not been possible to get a plate developed to show how it would work. Mr. J. D. Ross thereafter read a short paper on *Enlarging*, finishing up with a demonstration on Eastman's bromide paper. The subjects were a statue of Hamlet and a view of Brechin Cathedral. Both turned out very successful, and, on the motion of the CHAIRMAN, Mr. Ross was thanked for his paper and demonstration. Messrs. Gregor Cumming and Alexander McLeod were admitted members. The lecture and exhibition of slides illustrating linen manufacture was fixed for December 14.

Manchester Photographic Society.—October 13, Annual Business Meeting, marking the thirty-seventh year of the Society's existence.—Mr. George Hartley and Mr. O. H. Webb were elected members. The report of the retiring Council was read and adopted, and the Treasurer's balance-sheet presented. These recorded a successful year, and showed the position of the Society to be satisfactory. During the counting of the votes for new Council, a large number of members' slides were shown on the screen. The result of the election of officers was announced as follows:—*President:* Mr. Abel Heywood, jun.—*Vice-Presidents:* Messrs. Alfred Brothers, F.R.A.S., T. Chilton, T. R. Cobley, H. M. Whitefield, and J. Wood.—*Council:* Messrs. A. H. Beckett, W. Blakeley, F. W. Burt, C. H. Coote, F. Edwards, J. T. Hughes, G. J. Johnson, H. V. Lawes, W. Tomlinson, and E. G. Wrigley.—*Hon. Treasurer:* Mr. W. G. Coote.—*Hon. Librarians:* Messrs. C. H. Coote and H. V. Lawes.—*Hon. Curator:* Mr. E. G. Wrigley.—*Hon. Secretary:* Mr. W. H. Farrow. Abstract of report: The Council have to record that the interest in the Society has been steadily maintained amongst the members, the attendance at the ordinary meetings having been equal to the average of the past few years, although there are a number whose more frequent presence would be greatly appreciated. There had been no dearth of matter at the meetings, rather, on the other hand, have the subjects broached been both numerous and varied, and productive of both instructive and interesting discussions. The lantern meetings have been all of a popular character, and were well attended by members and friends. The outdoor meetings have not been very successful as a whole, although several pleasant rambles took place. A sub-committee appointed to consider the advisability of formulating recommendations as to the supply of compressed gas under Government regulations, had decided that very little action could be taken until after the Parliamentary elections. The Council recommended that an exhibition should be held next March. The Council tendered their thanks to the many firms and publishers who had contributed apparatus and matter during the past year. In retiring, the Council expressed the hope that the members would accord the same hearty support to their successors that had been given them, and which was ample thanks for the time they had devoted to the interests of the Society.

Sunderland Photographic Association.—The annual meeting of the above Association was held on the 19th inst., Mr. J. Lynn in the chair.—The report which was presented shows the Society to be in a flourishing condition, there being sixty-four members on the roll. The officers for the coming year were elected as follows:—*President:* Mr. W. Milburn.—*Vice-Presidents:* Messrs. J. Lynn and W. Pratt.—*Council:* Messrs. W. Bartram, J. W. Broderick, A. G. Boulton, E. R. Kirkley, Dr. Legat, W. J. Pope, A. Peddie, R. Stafford. *Hon. Treasurer:* T. Walton.—*Hon. Secretary:* C. E. Cowper, Thornhill-gardens, Sunderland.

ALDENHAM INSTITUTE CAMERA CLUB.—The following is a provisional programme for the coming winter:—*Developing* (Demonstration). *Retouching* (Demonstration). *The Human Eye as a Camera Obscura* (Continuation of Lecture by Mr. A. Hair). *Platinotype Printing* (Demonstration). *Gelatino-Chloride Paper* (Demonstration). *With the Convention at Edinburgh* (Lantern Evening). Lecture on *Optics*. *A Jaunt through Belgium* (Lantern evening). Other demonstrations, competitions, and excursions will be arranged, due notice of which will be posted on the notice-board.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

A BLACK SHEEP.

To the EDITOR.

SIR,—Under the heading, "A Black Sheep," you mention in your issue of last week the exposure of a professional photographer who seems to have certainly very much misbehaved himself, and deserves probably more punishment than he is likely to get.

My reason for referring to the paragraph is to emphasise your action in stating clearly the religion of the culprit. It must be of considerable interest to the public to ascertain this, and I think you might further add to your information a detailed list of the religions professed by Neill Cream, Deeming, the late lamented W. Palmer, and other offenders. You will then show clearly, what you were no doubt eager to do by your previous publication, what an extraordinary thing it is for a Jew to indulge in moral and legal turpitude!—I am, yours, &c.

HENRY E. DAVIS.

Camera Club, Charing Cross-road, W.C., October 24, 1892.

[Good friend, in stating that Sauvy was a Polish Jew, our intention was simply that of most persons who use that, or any similar phrase, namely, to indicate his nationality, not his religion. As a matter of fact, we gathered the information from *Spy*. The circumstance that some of the most esteemed friends of ourselves and of this JOURNAL are, as Mr. Davis himself is perfectly well aware, of the Jewish religion, should surely show that we are guiltless of any intentional impropriety in the matter.—ED.]

EXPANSION OF AMMONIA ON DILUTION.

To the EDITOR.

SIR,—In reply to Mr. Cadett's letter in THE BRITISH JOURNAL OF PHOTOGRAPHY of the 14th inst., allow me to draw his attention to what is said in Watts' *Dictionary of Chemistry* on the authority of the late Dr. Ure: "One volume of water by absorbing 505 volumes of ammonia forms a solution occupying 1·5 volumes, and having a specific gravity of 0·9. This, when mixed with an equal bulk of water, yields a liquid of specific gravity 0·9455, whence it appears that aqueous ammonia expands on dilution." Such a mixture ought, according to Griffin, to occupy a volume 2; but, if we calculate from the above data, we find that it occupies 2·0084 volumes, giving an increase of volume corresponding to 0·42 per cent. The number I obtained from the rough experiment I made lately gave an increase of 0·37 per cent., showing that I was not very far from the truth.

If Mr. Griffin's tables were calculated on the assumption that there is no increase in volume when ammonia is diluted with water, they must be wrong.

The whole matter can be easily settled by obtaining the reply to the following question: Does ammonia on dilution expand, or is the volume of the diluted ammonia the sum of the volumes of the constituents? I have given my answer above, and I hope Mr. Cadett will repeat that simple experiment I referred to at the London and Provincial Photographic Association, with all the necessary precautions, and report the result. I am convinced that, when he has done so, his faith in the particular tables will not be as great as it is at present.

The most recent researches on the connexion between specific gravity and percentage of ammonia in different solutions do not agree with the tables given by Griffin.

I never made any allusion to the expansion affecting results practically. All that I wished to draw attention to was the statement that ammonia differed from all other liquids in neither expanding nor contracting on being diluted with water, and that calculations based on that assumption must be erroneous; but this departure from the straight line may not introduce serious errors in practice.—I am, yours, &c., A. HADDON.

R. N. College, Greenwich, S.E., October 22, 1892.

"THE PHOTOGRAPHERS' BENEVOLENT."

To the EDITOR

SIR,—I thank you for the space you gave for my letter of last week, *re* the Benevolent. It may interest you to know that it has caused one case of apparently critical distress, which can be relieved by a temporary loan, to be brought before us. We have given temporary assistance in one or two other cases, and have several cases in our hands of assistants wanting places. One typical case is of an operator and retoucher, who has nearly twenty years' excellent testimonial from one of the best firms of photographers in the country. Over a year ago he emigrated on an engagement, and found, to his deep disappointment, that the firm to whom he had gone was "no good." He picked up a month's work as a temporary hand, was out of work for a week or two, and then, robbed of everything, including his specimens, worked a passage back to England, and has spent nearly a year answering advertisements and looking for work. No specimens, no good. Is now broken in fortune, and almost broken-spirited, but hoping against hope, and unwilling to take money from us, or to lay his case before the Committee at all. In seeking work, he has tramped as much as seventy miles, sheltering at night in coach-houses to husband his last shilling or two, which is rather hard on a man who has mixed with the best of photographic society.

This is one of the cases that ought not to occur if more general interest were taken in the Benevolent, and if photographers wanting assistants would apply to us. Is there any good house near London that will give this gentleman a week's trial even, or a temporary berth? His references are excellent.

We have another case, almost as bad, of a really good man who is working, and has been doing so all the summer, at a mere pittance—one of those places with a small salary and large commission (in theory), but with little or no commission in practice. We have almost all classes of assistants on the books.—I am, yours, &c., H. SNOWDEN WARD,

Memorial Hall, E.C., October 25, 1892. *Hon. Secretary.*

THE IMPERIAL PORTRAIT ASSOCIATION.

To the EDITOR.

SIR,—Every one knows that the final cause of hawks is pigeons; but, thanks to your pages, "The Imperial Portrait Association," with its respectably named and self-accredited President, hailing from Folkestone, and its generous offer of "an exquisite Fusain portrait, free of charge," will not find its prey in yours, &c., WM. C. LEDGER.

Lisnaskea, Iraland, October 24, 1892.

[Our correspondent encloses one of Mr. "Charles Beresford's" usual circulars.—ED.]

TUNBRIDGE WELLS AND EXETER ASSOCIATIONS.

To the EDITOR.

SIR,—Will you please announce that the following gentlemen have kindly consented to act as Judges at our forthcoming Exhibition, viz., Colonel Gale, Mr. George Davison, and Mr. William Mayland?—I am, yours, &c., JOSEPH CHAMBERLAIN, *Hon. Sec.*

Tunbridge Wells Amateur Photographic Association, October 24, 1892.

To the EDITOR.

SIR,—Will you kindly allow me, through the medium of your columns, to inform the numerous applicants for entry forms for our Exhibition, that the latter part of rule 2, prohibiting marks on the face of exhibits, is not intended to exclude the *titles* of pictures.—I am, yours, &c.,

JOHN SPARSHATT, *Hon. Secretary.*

Fairfield House, Alphington-road, Exeter, October 24, 1892.

HARDENING BY CHROME ALUM.

To the EDITOR.

SIR,—Referring to your second leader of August 5, can you give me a rough idea of the strength of chrome alum solution, which will harden gelatine films as, say, a five per cent. solution of potash alum?

The table of solubilities in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC does not give the figures for chrome alum. Can you supply the omission?

Would the solution of chrome alum and meta-bisulphite of potash, which you recommend as a combined clearing and hardening bath, be a stable solution, and what quantities of the two salts should it contain?—I am, yours, &c., S. A. M.

[See leading article elsewhere.—ED.]

AN ELECTRIC RETOUCHER.

To the EDITOR.

SIR,—Referring to your article in last week's JOURNAL, taken from *Anthony's Bulletin*, about "Retouching by Electricity," it presents a significant announcement in what direction the photography of the day is really travelling. Retouching is practised bad enough nowadays by girls and boys, bare of any knowledge of drawing &c., without wanting electricity. *Anthony's Bulletin* says: "A cabinet bust portrait may easily be completely retouched in fifteen minutes, entailing but little fatigue to the operator." Indeed? After this remark we may guess what sort of work here is referred to.—I am, yours, &c., F. B.

October 25, 1892.

MANUFACTURERS AND EXHIBITIONS.

To the EDITOR.

SIR,—The season has now approached when many exhibitions are taking place throughout the country, and manufacturers of specialities are requested to exhibit some of their latest goods. A great deal is usually

promised by the person applying as to the care that will be exercised in showing the articles and returning same; but my experience is a sorry one, for, if the goods have been fairly handled (I say nothing of soiling), the repacking is simply vile—possibly left to some person who never packed a box in their lives. Polished goods sent in tissue-paper will be returned bare, a burnisher tumbling about with mahogany cameras, and anchlike idiotcy. Perhaps others have experienced the same kind of thing, and, like myself, almost vow not to exhibit again. If secretaries of societies and others desire to show the goods of manufacturers, and there is constantly an incentive on both sides to be up to date, the least that can be done in common justice to the exhibitor is to see personally that goods are properly and sensibly packed, so that no loss or quibble arises in a mutual arrangement.—I am, yours, &c.,

57, *High-street, Aston, Birmingham, October* 20, 1892. WM. TYLAR.

Exchange Column.

**** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

An American hunting lever watch, cost 4*l.* 4*s.* lately; will exchange for whole or half-plate set.—Address, H. L. JEFFERIES, King-street, Maidenhead.

Will exchange Lancaster's Omnigraph detective camera for Thornton-Pickard shutter, two and a half inches diameter.—Address M., 2, Cheapside, Bolton.

Wanted, studio accessories in exchange for combined hot and cold roller, cabinet size, cost 10*l.*—Address, S. PATTERSON, Old Chesterfield Arms, Mayfair, W.

Wanted, developing and printing sets for half-plate camera; exchange, Rippingill's 50*s.* oil hot-water stove.—Address, A. H. SALMON, 29, St. Swithin's-lane, E.C.

Wanted, 9×7 Ross's rapid symmetrical, will exchange for first-class double canoe, paddle or sailing, complete.—Address, H. MOSEL, Market-place, Nottingham.

I will exchange violin and bow in ebonised case for a half-plate camera with all movements.—Address, R. MERRETT, Photographer, Russle-street, Stroud, Gloucestershire.

Will exchange four-back posing-chair, excellent condition, for half-plate camera and three slides; also studio stand in exchange for burnisher or printing frame 20×16; half-plate studio camera, bellows-body, rackwork adjustment, in exchange for quarter plate set or detective camera; also rustic studio set furniture for magic lantern.—Address, BEAVAN & Co., 11, Windsor-terrace, Newport, Mon.

LEWISHAM PHOTOGRAPHIC SOCIETY.—November 4, *Lantern Slides by Reduction.*

WEST LONDON PHOTOGRAPHIC SOCIETY.—October 28, Presidential Address and Lantern.

PHOTOGRAPHIC CLUB.—November 2, Annual Meeting (members only). 9, Members' Open Night.

PUTNEY PHOTOGRAPHIC SOCIETY.—October 31, Dr. Jeserich on *Photography Applied to the Detection of Crime.* November 7: Mr. Buchanan Wollaston on *Platinum Printing Processes.*

HACKNEY PHOTOGRAPHIC SOCIETY.—November 1, *Lantern Slide Making*, by J. Carpenter (flower-study fame). 8, Members' Lantern Night. 15, 16, and 17, Exhibition at Morley Hall. 22, Open Night.

MESSRS. MIELL & RIDLEY, 3, Victoria-buildings, Old Christchurch-road Bournemouth, have purchased the whole of the negatives and goodwill of the business, for the past eight years carried on by Mr. J. Vaughan, at Firs Glen Studio, Bournemouth.

LAST week, in criticising Mr. H. P. Robinson's charming landscape, *Midsummer*, now on view at the Camera Club Exhibition, the printers made us apply to it the epithet "extraordinary." The word, however, is not misplaced in regard to the excellence of the picture, which was the quality we, of course, had in mind and intended to express.

WE understand that Herr Anschutz, of Berlin, the inventor of the hand camera bearing his name, and whose clever photographs of animals have excited such general admiration, is on a visit to this country *en route* for the United States. Opportunity was recently taken of his presence here to invite several persons, well known in the world of photography, such as Miss Catherine Weed Barnes, Mr. L. Warnerke, and others, to accompany Herr Anschutz on a photographic outing up the Thames, when an agreeable time, pleasantly diversified by camera work on river scenery, &c., was passed.

IN the Queen's Bench Division, on Wednesday, an appeal was heard against the decision of the borough magistrates in the action of the Corporation of Leicester against George Brown, photographer, of London-road. It will be remembered that in May last Mr. Brown was summoned under the Public Health Buildings and Streets Act of 1888 for having, "without the consent of the Urban Sanitary Authority, erected a wooden building with a glass front in London-road beyond the main front wall of the house or building on either side thereof in the same street." A second summons charged Mr. Brown under the same Act with having, without the consent of the authority, built a "certain addition to a certain house" occupied by him on London-road. After a long hearing the Bench fined defendant 10*s.* and costs, but, on the application of the defendant, granted a case on a point of law. In the hearing of the appeal Mr. A. Toller (instructed by the Town Clerk) appeared for the Corporation, and Mr. Rawlinson (instructed by Messrs. Parsons, Wykes, & Davis) was for defendant. After a two hours' argument Justices Pollock and Hawkins upheld the decision of the magistrates.

GREENWICH PHOTOGRAPHIC SOCIETY.—A meeting was held on Wednesday, October 19, at the Lecture Hall, Greenwich, at which Mr. E. W. Maunder, F.R.A.S., presided, "to consider the advisability of forming a Photographic Society for Greenwich." After introductory remarks by the Chairman, Mr. Haddon gave a short account of method of procedure in such societies as he was acquainted with. The Chairman, resuming, pointed out that the project was warmly supported by the officials of the Royal Observatory and Royal Naval College, and by several local amateurs. A series of propositions having been put and carried unanimously, the meeting resulted in the formation of the "Greenwich Photographic Society." The Executive will consist of the following gentlemen:—*President:* Rev. Brooke Lambert, M.A., B.C.L.—*Vice-Presidents:* Messrs. A. Haddon and H. H. Turner, M.A.—*Committee:* Messrs. E. W. Maunder, F.R.A.S.; Arthur Martin; T. Lewis, F.R.A.S.; Dr. Waghorn; J. Q. Braidwood; J. H. Kingdon; G. S. Criswick, F.R.A.S.; R. Lewis, and W. Ellis, F.R.A.S.—*Hon. Treasurer:* Mr. Charles C. Churchill, 5, Annandale-road, Greenwich.—*Hon. Secretary:* Mr. Leon J. Atkinson, 193, Greenwich-road, S.E. Applications for membership may be made to Secretary or Treasurer. Subscriptions 5*s.*, payable to Treasurer. The first meeting of the new Society will take place at the earliest possible date. Upwards of forty ladies and gentlemen have already signified their intention to join the Society.

A FIRE IN PERTH.—On October 10 the studio and the whole of the contents, besides the stock, fittings, and many valuable prints on the walls, belonging to Mr. John Henderson, photographer, Hospital-street, Perth, were destroyed by fire. The scene of the fire, a large tenement of three stories and attics, fronts Hospital-street. One of the shops is connected with the studio by a covered-in passage. About eight o'clock Mr. John Henderson, jun., who resides in Hospital-street, noticed flames issuing from the studio, and at once gave the alarm, while word was sent to the Police-office for the fire brigade. As the studio was composed entirely of wood, and contained a quantity of chemical matter, the flames made rapid progress, and by the time the fire brigade arrived, under Captain Masterton, large volumes of flames were shooting up from it. It was some time before the water could be turned on, and then all that could be done was to prevent the flames extending to the front premises. In this the firemen were only partially successful, for the passage leading to the shop gave ready ingress to the flames; but, as soon as the fire was discovered to have penetrated into the shop, water was turned on to it. The large plate-glass window was entirely shivered by the force of the water, and before the fire was got out in the shop many valuable prints on the walls were burnt. In the studio were many negatives of considerable value, but, despite everything that could be done to save them, these could not be got out; and, although the water was kept pouring on the flames, it was seen that the task of subduing them was a hopeless one, and that the fire must burn itself out. Luckily, the wind was not very high, but the heat was very oppressive, and the firemen had great difficulty in approaching the fire. The door of Mr. Henderson's house, which stands detached from the studio a distance of about a dozen yards, was scorched. The fire brigade from the Queen's Barracks arrived when the fire was nearly over, and their services were not required. All that Mr. Henderson succeeded in saving was one or two cameras. In the studio were about 30,000 negatives, the gathering of a lifetime, for Mr. Henderson's business was one of the oldest-established in the city, and they were all destroyed. Also on the walls of the studio were a large number of prints, and they were burnt. After blazing for about an hour the fire burnt itself out. Nothing was left standing. The damage to the stock is estimated at nearly 1000*l.*, although many of the negatives were so valuable that a much higher valuation might be put upon them. The studio and the contents were uninsured, but the tenement in front was insured. The origin of the fire is unknown.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Mackintosh & Co., Kelso.—*Portrait of James Henry Robert Innes-Ker, seventh Duke of Roxburghe.*

Henry Buttrum, Stony Stratford.—*North Bucks Conservative Association. Meeting of the Council at Gayhurst House on September* 28, 1892.

** Various interesting communications, "Our Editorial Table," and several answers to correspondents are held over on account of the great press of matter this week. We hope to overtake the arrears next week.

A. CHARLES.—Communicate with the local superintendent of police.

OPTICIAN.—For soldering aluminium, try chloride of silver as a flux.

A. G. R.—1 and 2. All the lenses we have seen by the maker you name have proved excellent.

S. V. W.—The information is a little difficult to obtain, but we will endeavour to obtain it for you next week.

W. OUIN.—Thanks for portrait. We are always glad to have the "counterfeit presentments" of friends in our album.

RICHARD SCRIVERS.—Many thanks, but we scarcely think a description of the clock can be of any interest to our readers.

A. B. says: "Can any one please give me a formula for bath that will give red tones to the Ilford 'printing-out' paper, or the 'collodio-chloride' emulsion paper?"

A. NEVILLE.—Albumen transparencies do not require varnishing. Indeed, they are better without. In this respect they are totally different from collodio-bromide transparencies.

J. P. J.—Domestic animals may sometimes be photographed more easily by the flashlight than they can be by daylight. But usually the picture must be secured at the first shot, as they are generally too frightened to be tried again, for some time at least.

F. JOHNSON.—Sandarac alone makes a somewhat brittle varnish for negatives. Shellac is better, but a mixture of the two resins is better still. The "new methylated spirit," or rather that methylated under the new regulations, will do quite well as a solvent.

TOMPO says:—"1. How would you test a gas bag in order to find out whether it is free from leakage (oxygen)? 2. Would you consider whole-plate rectilinear suitable for lantern, long distance, with limelight?"—1. Simply with water. 2. No; better use a portrait lens.

W. L. CUMMINS.—By consulting pp. 856,857 of the ALMANAC for 1892, you will find tables that will enable you to convert the French into English weights and measures. The solution referred to is for development, the potassium chloride being used to influence the tone.

B. LABES says: "In your last issue I find an article about Retouching by Electricity. Being desirous of obtaining a pencil of that kind, I should be pleased if you would forward particulars, price, &c."—You had better apply to Messrs. E. & H. P. Anthony & Co., of New York.

R. W.—No special treatment or precautions are necessary in taking frost pictures beyond the adoption of the same care in the development that is always required to secure a good negative. Give a full exposure, but do not over-expose. If opportunity will permit, use the camera on a stand in preference to holding it in the hand.

OLD SUBSCRIBER says: "Will you say which of the mechanical processes you would consider best for a photographer to introduce, *i.e.*, for reproducing groups, photographs, or views in quantities from original negatives, both cheaply and expeditiously, consistent with best results?"—Undoubtedly th collotype process would be the most suitable for your purpose.

O. P. T.—Only duly qualified pharmaceutical chemists are allowed to sell the poisons mentioned in your list, and then only when certain conditions are complied with. The chemicals being employed for photographic purposes makes no difference whatever. Others certainly sell them, as some of them may be had at the oilshops, but the vendor does it at his own risk—a heavy penalty.

D. BARNICOTT says: "I notice in your issue of THE BRITISH JOURNAL OF PHOTOGRAPHY for September 16, 1892, No. 1689, you have a leader on a mountant, in which you mention Opie's Medium. Will you kindly inform me where I can obtain this?"—The "medium" in question is not, so far as we are aware, an article of commerce. It is known in the vulgate as "brains."

BEGINNER says: "Being interested in and desirous of obtaining a knowledge of the art of photography, I should feel much obliged if you would tell me where I could get a book on the subject—one that would give good information to a beginner, and that would be not too expensive."—Read the elementary chapters addressed to a beginner in the last volume of the ALMANAC.

H. SIMMONS.—We are not aware of any sponge lamps burning benzoline that are preferable to the ordinary ones consuming paraffin oil, or indeed that are at all suitable for the purpose. We have seen large lamps on the sponge-lamp principle with a multiplicity of wicks that give excellent illumination in a room. The light, however, was not nearly so well adapted for the lantern purposes as the usual ones with which it is usually fitted.

J. R. G.—It is somewhat difficult to say the exact cause of failure from the data given. It would seem, however, to be due to an unsuitable pyroxyline and an insufficiency of bromide of silver in the emulsion. The latter would be the case if the whole of the bromide salts did not dissolve. As you fail with the double salt, and succeed with the zinc bromide, we should advise you to keep to that, and try two or three fresh samples of pyroxyline.

T. HINE.—Plates that have been exposed to light can be treated so that they are again made fit for negatives; but, as plates are now so cheap, no one cares to go to the trouble of restoring spoilt plates. If it is not worth the while of makers, who have all appliances ready to hand, to do so, it may be taken for granted that it is not worth a photographer's while to fit up the necessary drying and other arrangements to deal with a few dozen injured plates?

PYRO sends a number of prints, several of which show large yellow patches on the surface, while others out of the same batch do not. He asks the reason. —The yellowness is clearly due to imperfect fixation. Most of the prints that our correspondent considers free from the evil are not really so, as they show decided yellow in places when examined by transmitted light. Either the time of immersion in the hyposulphite bath was too brief, or the solution was not strong enough. The remedy is obvious.

A. FLINT says: "Would you assist me by giving me the particulars, or let me know where I can obtain a good flashlight for studio work at a fairly moderate price, not to exceed ten pounds, or thereabouts. My studio is only about eight feet six inches wide by seventeen feet long, so I have not much width for reflectors. What I want is a lamp that will give first-class results.—There are several such on the market, but it is not our rule to give preference to any single one. Call at two or three dealer's, and you will no doubt be able to suit yourself.

B. M. (Auglet, France).—"May I ask your advice in a dilemma? I am greatly annoyed of late to find pinholes, and even large ones, on the surface of my plates after developing and fixing. I do not remark them until the plate has been fixed. I use the utmost caution both in developing and washing, and cannot see where these pinholes come from. In some cases the spots are as large as a pea."—The trouble arises from dust on the plates, or air-bubbles adhering to the film during development. Probably the two combined—the large spots from the latter, and the small pinholes from the former.

L. A. S.—It is perfectly true, as you have been told, that carbon pictures may, if kept against a damp wall, become mildewed; but the chances of their doing so are somewhat remote. Engravings kept under similar conditions may also become mouldy. Mildewed engravings are by no means uncommon. Under the conditions of moisture, assisted by warmth—the conditions of an ordinary dwelling-room that is damp—carbon pictures will suffer infinitely less than will silver prints, whether on albumen or gelatine paper. So far as permanency is concerned, there is no difference between engravings and photogravures.

H. SINGLETON complains that the oil lamp of his lantern gives off a very unpleasant odour when alight, and asks if this is common to all lamps burning paraffin oil.—It is, unless they are kept scrupulously clean. In most cases the smell proceeds from oil on the outside of the lamp and its fittings. In all cases every part of the lamp should be carefully wiped with a clean cloth just before it is lighted, and the wicks carefully trimmed. When the lamp is finished with, all oil should be drained out, to be refilled only when again required for use. If these points be attended to and good oil used, there will be but little, if any, offensive fumes given off.

A. C. says he cannot succeed in making a solution of indiarubber in benzole, although he has tried several kinds (not vulcanised) of rubber. The rubber, he adds, swells up something like gelatine does in water, but it does not dissolve.—All kinds of rubber do not dissolve readily in benzole; but, if what is known as "masticated rubber" be used, there will be no difficulty with ordinary benzole. The most convenient way to obtain a solution of indiarubber is to purchase a tin of the ordinary "solution," such as that sold by Hancocks and others for repairing macintoshes and suchlike things, and dilute it with benzole to the consistence required. This will sometimes save a deal of trouble.

REX says: "I purchased a lens (front) for magic lantern. Back lens is two inches diameter. It is one of the ordinary kind, with flap shutter. The focus is four inches. I am dissatisfied with its performance, as the picture, when projected on the screen, is not sharp at the edges or margin of the screen. When the centre is sharp the sides are blunt, and *vice versâ*. How can I remedy this defect, as the lens is new and cost about a guinea? If one of the lenses of the combination requires a new one, please say which, and the probable cost, and if a longer focus than the four-inch would be desirable."—No advice that we could give you would improve the lens. Return it to the vendor and endeavour to let him have one with a flatter field.

E. H. W. says: "I had in two reams of albumenised paper, from which I have been using for some time past. I now find that water from a leaky pipe has been trickling on to the bench where the paper has laid. The consequence is, that the wet has penetrated about half way up the lot, and stuck the sheets together, so that they can only be separated with difficulty, and then the surface looks dull in places when the paper is dried. What can be done, as, unless I can make the paper usable, the loss will be serious to me, as I am only in a small way of business?"—The circumstance is unfortunate, and we fear there is no remedy. Our impression is, that it will be cheaper in the end to discard the paper altogether than to sensitise it, as much of it will afterwards have to be wasted. When once albumen ha become damp, it is of very little use.

JOURNAL OF PHOTOGRAPHY.

No. 1696. Vol. XXXIX.—NOVEMBER 4, 1892.

GELATINE *VERSUS* STARCH AS A MOUNTANT.

The majority of photographers employ starch paste for mounting pictures, while professional print-mounters, as a rule, use gelatine, or, more often perhaps, common glue. Several have at times remarked to us that they would prefer gelatine as a mountant if it were not so difficult to manage. In practice, however, when the proper conditions are understood, the difficulties prove more imaginary than real. It has frequently been stated that prints mounted with gelatine last longer than those mounted with starch. This is probably the case when the mounts contain injurious matters, as the layer of intervening gelatine is a better insulator than one of starch. This better insulating property is also a great advantage with some of the deeply coloured mounts in which the colouring matter is partially soluble in water. If with such mounts starch be used, there is a danger of the whites in vignetted prints becoming stained, whereas, if gelatine be employed, the trouble will, except in very bad cases, be avoided, because before the pigmented coating on the mount has become fairly wetted the gelatine has set, and, so to speak, formed a protecting layer.

Many who have tried gelatine as a mountant have failed to use it successfully. The failure, however, can generally be traced to one or other of two causes, or, perhaps, the two combined. The first is the employment of an unsuitable gelatine; the second, using too thick a solution. Some would consider that for the present purpose the highest class of gelatine should be employed. This is a mistake, for the very lowest is by far the best for the work. If a solution of one of the highest qualities of gelatines, such, for example, as those used for dry plates, be made and applied to the back of a print, it will be found that before the whole can be evenly coated, even when its dimensions are small, that which was first applied has set, and when once it has set it has lost the greater part of its adhesiveness, and can then only be made to adhere, if at all, by heavy pressure or hard rubbing. This trouble may to a certain extent, it is true, be mitigated by diluting the solution, but it does not overcome it.

If, instead of using a gelatine of the character just referred to, we take common glue, as sold in the shops at a few pence a pound, and make a solution of that of the same strength as the gelatine, and use it at a similar temperature, we shall find no difficulty in coating even large prints before any portions begin to gelatinise. For this reason common glue, in practice, proves more adhesive than the finest quality of gelatine. Reference has just been made to failures arising from the employment of too strong a solution. The stronger it is the quicker it will set, while very dilute solutions will require a comparatively long time before they will assume a jellied condition. So adhesive is this material, that those who have not tried it will be surprised how weak a solution of common glue will serve for sticking papers together.

Reference has been made to common glue; but, be it understood, only as an example of its properties as compared with those of the best gelatines. It will be manifest to all who know anything of the subject that its employment for mounting silver prints should be eschewed if their permanence is a consideration, owing to the impurities with which it is always contaminated. It is, also, almost invariably acid, as, indeed, are the highest qualities of foreign gelatine, which, quite apart from their quick-setting properties, render them unfit for mounting photographs. It will now be seen that what is required for the purpose is a pure kind of gelatine with the mechanical properties of the common glue. This we can obtain in some of the gelatines of British manufacture. They are known commercially under the name of "soup gelatine" or "soup strengthener." Nelson's, Cox's, and other firms supply such gelatines, and they can be relied upon, while, at the same time, they are very inexpensive. The first-named firm also supply a gelatine known as "No. 2 soluble." This is an excellent gelatine for the purpose, as it combines purity with slow-setting properties. It may almost be taken for granted that English gelatines of fair quality are always neutral, while foreign ones are invariably acid.

It is impossible to give a definite formula for making a solution, as different samples of gelatine vary so much; but the weaker it is, so long as it will stick, the more convenient it will be to use, and the less heat will be required to retain it in a fluid state. As a rough guide, it may be mentioned that such a proportion as will form a weak, though not too tremulous, jelly after standing in a cool place all night, will be found most convenient in every way. It may also be mentioned in connexion with the strength of the solution that the more dilute it is the shorter will be the time it will keep without decomposition. Hence it is desirable, when preparing several days' supply, to add an antiseptic, such as a few drops of oil of cloves, or, better still, a little methylated alcohol. Alcohol can not only be used as an antiseptic, but it can be made largely to take the place of water in the solution. An adhesive, so prepared, is extensively used for mounting prints on boards with a clear margin so as to avoid the cockling of the mount; but, as this portion of the subject has been so frequently dealt with, it need not be referred to on this occasion.

One other matter may, however, be alluded to in connexion with the use of gelatine—namely, mounting photographs in optical contact with glass. Some have employed the higher classes of foreign gelatines on account of their whiteness and trans-

parency. To this fact may be attributed the difficulties many have experienced in the work, and also the existence of so many fading pictures. These gelatines, as we have just said, are difficult of application, and, by reason of their acidity, conducive to fading. However, by employing the class just recommended these inconveniences are avoided, while the purity of the whites of the prints will in no way suffer from the apparent slight opacity and trifling tint of the gelatine.

DAMP AND GELATINO-CHLORIDE PAPER.

Since writing a fortnight ago on *The Storage and Treatment of Sensitised Paper*, the weather has been in every way favourable for experimenting on the effects of damp, and we have consequently been endeavouring to demonstrate graphically the deleterious influence of moisture in the atmosphere upon our more modern sensitised papers.

Selecting a number of felt pads of half-plate size, these were placed in the kitchen oven for several hours until thoroughly dry, and were then found to average very slightly over two hundred grains each when weighed. They were then hung up for a couple of days in a room without a fire in order that they might absorb as much moisture as possible, or acquire as nearly as might be the characteristics of carelessly kept pads. When again weighed they were found to have increased in weight to the extent of close upon thirty grains each, or nearly one-sixth of the total weight of the pad had been absorbed in the form of moisture.

To the touch there was no feeling of dampness nor any appearance to lead to the suspicion that the pads were anything but "bone dry" and yet when held to the fire, steam or vapour was given off freely and continued to be evolved for upwards of half an hour, showing how difficult it is to thoroughly eliminate the moisture from such thick material.

In order to practically test the effect of such damp backing upon various kinds of paper, samples of ordinary "ready-sensitised" as well as freshly sensitised albumen paper, two commercial brands of gelatino-chloride "printing-out" paper, and one of collodio-chloride paper were selected for trial, and as a contrast a piece of gelatino-bromide paper intended for development was put through the same treatment in order to demonstrate the influence exercised by the soluble matter contained in the various films.

Pieces of the respective papers were placed in printing frames backed up with the damp felt pads, but with a strip of tinfoil placed across the centre of each in order to isolate a portion of the surface from the possible action of moisture. The commercial papers were used in the state in which they came from the package, and those of home preparation were just thoroughly dried and then submitted to the atmosphere for a quarter of an hour in order to allow them to absorb the amount of moisture necessary for satisfactory printing.

With the exception of the gelatino-bromide paper, the other samples were printed in the ordinary manner, and under precisely similar conditions, and when the printing was finished the frames were set on one side for a week without removing the prints. The gelatino-bromide paper received an exposure to artificial light and was then placed with the rest, receiving precisely similar treatment.

At the end of the week the last-named paper was developed, and, beyond the fact that it was sensibly more "limp" than a fresh piece taken directly from the original packet, it differed in no way from the latter in its behaviour, showing that at least during the period of a week no ill effect accrued from the action of damp. This, it must be observed, is in the entire absence of soluble matter.

Turning to the printing-out paper, the two samples of albumenised were first examined. The ready-sensitised exhibited at this stage no visible traces of the effect of moisture, the preservative material employed in the manufacture sufficing to keep the colour of the paper intact; but the home-sensitised sample showed a very palpable band of purer colour where the tinfoil had protected it. Looking at the back of the paper, a very decided yellow colour pervaded the whole of the unprotected portions, while even under the tinfoil a slight yellowing had taken place.

In the case of the two samples of gelatino-chloride paper, the effect was somewhat different and rather curious. No discolouration in the sense of yellowing was noticeable either on the print itself or on the reverse side of the paper; but, on examining the gelatine surface, there was distinct evidence of a sort of "bronzing" or metallic iridescence on the unprotected portions, and showing clearly by a distinct line against the portion where the tinfoil had been. The effect was more marked in one case than the other, but was sufficiently plain in both to leave no doubt as to the protective influence of the tinfoil.

To show that the effect of moisture does not show itself only with such highly organic compounds as those of silver with albumen or gelatine, it may be recorded that the collodio-chloride paper was at this stage more strongly discoloured than any of the others; and not only so, but the injury produced proved to be more permanent, that is to say, the yellowing produced upon the albumenised paper disappeared in the subsequent toning, which was not the case with collodio-chloride, nor was the "bronzing" effect in the latter instance reduced to the same extent as with gelatino-chloride.

The whole of the prints were then toned and fixed, and the results were similar in character throughout. Where the protective tinfoil had been, the toning was not only more rapid, but a better colour was produced, and the protected portions were entirely free from a slight metallic surface lustre that pervaded the whole of the remaining portions. This was not so noticeable as the difference in tone produced by the damp, the latter being, of course, emphasised by the sharp line of demarcation; but both effects were sufficiently pronounced to spoil the quality of an otherwise perfect print.

We commend these experiments to the attention of our readers who may still be engaged in printing operations, and would strongly urge them to look carefully to the condition of their printing frames and pads.

The National Association of Professional Photographers.—We are informed by the Secretary that the Council of the National Association of Professional Photographers will meet on Wednesday, November 9, 1892, at Anderton's Hotel, Fleet-street, London, 7 p.m., for general business, and that the presence of *all members of the profession*, whether belonging to the Association or not, is earnestly desired and invited. The chair will be taken by Mr. Thomas Fall (London), the President, and the Secretary, D. J. McNeill, 47, Charlotte-road, Birmingham, will be pleased to receive communications and to reply to inquiries.

Glass-lined Tubes.—We recently chronicled a new variety of glass-ware in the shape of vessels of that material in which woven wire was embedded. The latest application of glass is in the manufacture of tubes, in which it forms the lining material. Messrs.

Dan Rylands & Co., Limited, are now making these tubes in a large variety of sizes. The tubes are made bent and T-shape as well as straight, and the company recommend them for household service, as by their use no danger of lead-poisoning can arise. They are stated to be safe from cracking by frost or any reasonable amount of hard wear. The joints between the lengths of tube when fitted are made by washers of guttapercha or other suitable material. It is evident that such tubes might be put to a variety of services of great value in photography.

A Discovery.—The Paris correspondent of the *Daily Telegraph* says: "Experiments in photography made by the Duc de Morny in his amateur studio at Levallois-Perret have led to a useful discovery. He has been able to photographically impress paper of any size or thickness. By this means a likeness can be fixed like a monogram on note-paper and on railway or other tickets. Eighty different *silhouettes* can be taken in a minute, and at small cost. The Duc de Morny has communicated his discovery to the Minister of War, who intends to utilise it in the 'books' carried by soldiers, and in which their descriptions, records of service, and so on are inscribed. The Russian Grand Dukes now in Paris have also decided to adopt the invention in the army of the Czar, and have asked the inventor to send one of his 'collaborators' to St. Petersburg." We await particulars of this "useful discovery," which, however, we conjecture is not new.

Discoveries in Astronomy by Photographic Means.—There is, however, no doubt that photography has recently played a very important part in scientific star detection, M. Charlois, of Nice, having discovered two more small planets, and Dr. Max Wolf, of Heidelberg, two others. Both observers made their discoveries on the same day, the 25th of September last. The aid of photography has been recommended to be called in with regard to the alleged newly discovered fifth satellite of Jupiter. It has been positively alleged that an additional satellite has been glimpsed in the telescope, but with regard to it, Mr. Plummer, the director of the Liverpool Observatory, says there are not wanting circumstances to make one hesitate before accepting its existence as a fact. Fortunately,' he continues, 'there remains one means of settling any ambiguity. It will offer a problem of no great difficulty to Mr. Isaac Roberts to take a few photographs of the district through which Jupiter has passed, and see what thirteen-magnitude stars lie sufficiently near the place of the planet to be mistaken for satellites on the night in question.

The Largest Telescope in the World.—There have been so many rumours about a new telescope, not to speak of the official notification recently described by us under the heading of "Wanted, a Big Telescope Donor," that there will be a certain amount of satisfaction in learning that it is an actual fact that the order is given for the "Largest Telescope in the World." It is for the University of Chicago, and is the gift of Mr. Charles T. Yerkes of that city, who said, "Get the best glass in the world, and send in the bill." It is estimated that this "bill" will amount to half a million of dollars, if not more. A very modest estimate, we should be inclined to say, when all the conditions and surroundings are taken into consideration. Mr. Burnham, Professor G. E. Hale, of the Kenwood Observatory, and Dr. Harper have consulted with Mr. Alvan G. Clark, and it has been decided to have a telescope with an object-glass of forty-five inches aperture, which, it will be seen, represents a light-collecting area about half as large again as the great Lick Telescope.

Noah's Ark.—Mr. Green, whose name is rather a suspicious one, writes to know if he can buy photographs of the original Noah's Ark. Lest our readers may not be aware what the reference amounts to we may say that the reverend gentleman named has written that on April 25 last he climbed Mount Ararat, discovered the Ark, walked round it with six companions, and contemplated it from various points of view. He was almost overcome, and was filled with gratitude. M. H. Cadoux ascended the mountain six weeks later, but found no trace of human work except what the Russian explorers had left, and he was further told that it was inaccessible in April. We really do not think we could give a better reply than a transcript of the words of the well-known scientific expert who writes to the *English Mechanic* under the pen name of "A Fellow of the Royal Astronomical Society." He thus says: "It seems to me a slight chronological mistake has crept into the account of Archdeacon J. J. Norris's discovery of the Ark . . . . Undoubtedly the discovery was made on the *First* of April, and not the twenty-fifth . . . . By a strange coincidence a gentleman named Annanias Okes on the very same day, after a gale of wind, picked up a dozen or two of the linch-pins out of Pharoah's chariots on the shore of the Red Sea; and by an even more curious coincidence a highly respectable tradesman in Wardour-street succeeded in securing the very sword that Balaam wished for." *Verbum sap.*

HAS ALBUMEN RECEIVED ITS DEATH-BLOW?

It will be remembered that three weeks ago, and as an append to a letter from the Britannia Works Co., relative to the uniformity of the tones obtainable on the Ilford Printing-out Paper (the 'P.O.P.' as it is usually termed), we spoke in terms endorsing their statement of this quality. This we did after a careful examination of from four to five dozen cabinet portraits which bore the name of W. H. Midwinter & Co., Bristol.

There was something so exquisitely beautiful and delicate, and vigorous withal about these pictures that we felt impelled to address a request to Mr. Midwinter for detailed information concerning his *modus operandi* for publication either in the JOURNAL or ALMANAC, or both, as we saw occasion. To this a courteous response was made, with an offer, should we find it convenient to visit his establishment, to afford us every facility for witnessing the whole of his operations from beginning to end, an offer of which we promptly availed ourselves.

From the high position Mr. Midwinter occupies in the profession and his long experience in photography we consider him, more than many others, entitled to speak with authority, a feeling that has been strengthened since we spent a forenoon in his admirably fitted-up ateliers in 48, Park-street, Bristol.

Conversing on the subject generally of our visit, we were informed that for a considerable time albumen had been entirely banished from his place, his printing now being confined to gelatine 'P.O.P.' and platinum. Information of this nature coming from such a representative man augured ill, we thought, for the long-continued tenure of the sway that albumen has had without any rival worthy of the name for these forty years past. Good old albumen! It has served us well during its reign; and, in the prospect of its being sooner or later deposed, we must endeavour to overlook demerits inseparable from its nature, and cherish its memory as that of an old friend who has rendered us good service. It is perhaps premature to cry, 'The king is dead! Long live the king!' but, remembering our forecast many years ago concerning the chances of collodion retreating in favour of gelatine as a factor in making negatives, we imagine that in course of time, and that too at a not distant period, albumen as an agent in printing will have to retire from the prominent position it has so long occupied.

Like so many other establishments, the printing room of Mr. Midwinter is covered in with glass, and it has the usual facilities for changing and filling the printing frames. It was, however, the subsequent treatment of the prints in which we were now more peculiarly interested.

Examining a few dozen prints as taken from the frames, we found that, contrary to the custom of some who use gelatino-chloride paper, these were slightly over-printed, not very much so, but to rather a less extent than adopted by experienced albumen printers. In the toning room, which is large and roomy, the utmost cleanliness and method prevail. Along one wall, that in which the windows are, there are ranged six slate tanks side by side. Above each there are water-taps, and in the bottom are two outlets, one to permit of relegating valuable waste to its suitable receptacle, the other communicating with the sewers. We observed that no sooner had a tank been done with than it was thoroughly washed, sides and bottom, with a large sponge; and we further observed that separate sets of

sponges and brushes are employed for the various tanks; thus, the brush for the hypo tank could not possibly be used in any but its own, unless one were wilfully to ignore the lettering on its back. This cleanliness and method are perhaps due to the fact of Mr. Midwinter having in early life graduated in a chemist's establishment, where, above all places, cleanliness and method must reign supreme.

The first operation was to immerse the prints one by one in a water bath, from which, after a good soaking, they were transferred to the alum bath. This consists of—

Alum	4 ounces.
Water	80 „

The chief printer—a most intelligent man—told us that he had at first adhered to the directions issued with the paper, which recommended *eight* ounces of alum to this quantity of water, but that he had reduced the strength to four ounces without any discoverable disadvantage. After remaining in the alum solution for ten minutes, the prints were then subjected to a wash in a succession of three changes of water. This washing was not done in a perfunctory, but in a thorough, manner. At this stage the prints had lost the purple tone they had when taken from the printing frame, and had acquired a red colour similar to that which albumen prints have at the stage after being immersed in a solution of chloride of sodium or acetic acid previous to being toned—a custom adopted by some.

The toning bath consists of—

Sulphocyanide of ammonium	30 grains.
Water	16 ounces.
Chloride of gold	2 grains.

Of this a quantity sufficient is poured into the toning dish to give the prints plenty of room in which to float about without danger of one sticking to the other. Mr. Midwinter strongly urged this as an important point both in convenience of working and as ensuring uniformity of tone. We noticed that in measuring out the toning solution two-thirds of the bath used the day previous were taken and refreshed with one-third of a new bath. This we think is an excellent system, viewed either economically or from the point of convenience, for in our estimation some of the toning baths employed with gelatino-chloride paper act too energetically to enable the requisite care to be taken in seeing that, when a considerable number of prints are being manipulated by one person, due care is taken in ensuring uniformity. How otherwise could it be when contrasted with the helter-skelter turning over of prints, accompanied by a fear to devote more than a very few seconds to the examination of any one print in case the others are in the meantime getting spoilt by over-toning? No occasion for such hurry when the toning solution is prepared as described. The printer here had time both to keep the prints in motion and to carefully and critically examine each one, which he did by transmitted light, holding it up against a gas-flame before him. The average time for a print to acquire a purple black tone is about from eight to ten minutes. During these various operations the prints were kept almost invariably face down in the various solutions.

The fixing bath consists of three ounces of hyposulphite of soda to the pint of water. The best quality of soda procurable, although costing somewhat more than that of average quality, is alone employed, as it is found cheapest in the long run, and Mr. Midwinter has been taught by experience that ten minutes in a solution of the above strength is sufficient to ensure the prints being thoroughly fixed. They are then washed for two hours in running water.

Let us pause for a moment to speak of the influence exerted by a bad sample of hypo upon the future of a print. Only a short time ago there was a perfect epidemic of spots on albumenised prints. Complaints respecting this reached us almost daily and from sources widely apart. No matter what care was taken or what brand of albumenised paper was employed, the plague prevailed. An observant professional friend in the North found that the prevalence of the spots in his case was concurrent with his using a certain kind of hypo which he had recently purchased. Acting on a surmise, he made two fixing baths, one with an old and the other with the new purchase. A brief period sufficed to establish the fact that the spots were attributable exclusively to the soda most recently procured. *How* it acted he could not tell; but that, in his case at any rate, it was the cause of the spotted prints he felt well assured. The subsequent employment of another sample ensured freedom from all farther annoyance. We have written this *apropos* of Mr. Midwinter's care in using anything but the best quality of hypo.

With regard to the toning bath, forty-eight grains of gold for toning forty-two sheets of paper, and toning them well, cannot be considered otherwise than as being strictly economical. This, we were informed, is the proportion indicated by experience. There was no mealiness or defects of like nature apparent in any of the work done under the conditions described; indeed, we were told that such is altogether unknown.

The mounting is performed in the manner in common practice by many, that is, the prints are taken from the water and piled, face down, one on the top of the other. The surplus water is removed by gentle pressure on the top, but not to such an extent as to cause adhesion between them; starch is applied to the top one, which is then attached to the mount, and so on to the end. After spotting, they are placed in a grooved box, to remain for burnishing, which is done the next morning. The grooved box has a perforated zinc bottom, and a drawer below in which two or more wet sponges are contained, the object being to prevent the prints becoming quite desiccated, which is inimical to their ultimately taking on the highest finish.

The burnisher, which acts the part rather of a hot roller than a burnisher pure and simple, is one of that form known as the Quadruplex Enameller, made by a Chicago firm. Having been passed through this a few times, the prints acquire a high glaze and finish; and to prevent any curling they are laid, face down, on a wooden table until cold; when taken up, they are quite flat. No lubricant is employed.

In the foregoing remarks we have given, in as brief a manner as possible, an account of the way in which we saw many gems of pictorial art produced. It is, however, proper that we should say that the negatives are pictorially and technically of great excellence. The former is doubtless owing to the fact that Mr. Midwinter, previous to becoming a photographer, had, on his return from the Crimean War, through which he had passed, gone in for an art education, and graduated as a painter; the latter is a consequence of care, method, and a knowledge of what a photograph should be.

Before leaving, we had a look over the studio and adjoining rooms. the studio has a "lean-to" roof, fitted with double—nay, with quadruple spring roller blinds, one pair of white and blue overlapping each other, and either of them capable of being raised or let down. There is also a side vertical light, looking on a garden the wall of which, with its trailing plants and boulders, seems well adapted for the posing of large groups against.

Mr. Harvey, the operator, a near relative of the proprietor, who has been since youth with the firm, seems to have the art of lighting and posing the sitter at his fingers' ends, for, in an incredibly short period, he manipulated the screens so as to produce any effect desired. The reception and adjoining rooms are decorated with the choicest examples of Mr. Midwinter's work, and forms quite an exhibition in itself.

The prices at this establishment are: 1*l.* a dozen for cabinets; 30*s.* for boudoirs; 2*l.* 2*s.* for imperials; and 3*l.* 12*s.* for panels.

In connexion with the finishing of gelatino-chloride prints, we have been shown some examples of a method adopted by Mr. W. Crooke, of Edinburgh, which imparts to the surface a delicate matt that for many purposes has a charming effect. We have not been apprised of the method employed in producing this matt, although the paper is of the same brand as that used by Mr. Midwinter. From some experiments of our own, however, since made, by interposing a film of matt celluloid between the burnisher and the photograph, which imparts the effect in question, we may suppose Mr. Crooke's method must bear some resemblance to this.

THE NEW DEVELOPER.

A FEW weeks' experience with "amidol" effectually convinces me that we have at hand still one more powerful and valuable addition to our list of photographic chemicals. Personally, I have never had

much respect for these "one-horse" developers, and having very rarely to complain of our old friend "pyro," they have not been favourite developers with me. Obviously, when working much with "shutters," something else is required at times—a developer, in fact, which may be allowed to remain on the plate, quietly doing its work, without unduly veiling the same.

The formula supplied by the makers is, I think, the best for the purpose, though, for those who have a fondness for the metabisulphite of potassium, *may* be used, if they wish, a small quantity of this salt, in place of the soda sulphite. A little experience here may not be out of place. The potass metabisulphite (80 grains in place of 800, of soda sulphite) was dissolved in eight ounces of water; eighty grains of amidol then added, the proper dilution followed, and a plate immersed—it remained submerged with the usual rocking for some fifteen minutes, when, no image appearing, the plate was removed, washed, and a sulpho-pyro ammonia developer mixed and applied. The result was satisfactory, but on getting into daylight I found my fingers badly stained a metallic-looking black stain, rather troublesome to remove. The amidol solution was neutralised afterwards with carbonate of soda, and has since developed several plates without trouble. However, I don't recommend metabisulphite in conjunction with amidol—it *will* do; but, if *fresh* and strong, it must be estimated to be twenty times the strength of sulphite of soda at least.

With the sulphite the developer is, in every way, as described by the makers, giving clear shadows a sufficiency of density, with a pleasing tone, conducive to quick printing, and is, without doubt, superior to pyro for certain exposures and subjects. As an instance, two plates, exposed on an interior, and receiving rather less exposure than would ordinarily be given, were developed, one with pyro and the other with amidol; the pyro was used in the way suggested by some years' experience, but there is halation and a want of detail in the shadows; the amidol-developed plate shows much less halation and more detail, but the development occupied perhaps twice the time. I find "rocking" still necessary as ever; it is not safe to leave the plate resting calmly in the solution; hence, unless one has a "rocker," it is tiring work; but all developers are much the same in this respect.

Finally, if any prematurely grey reader wants a good and cheap hair dye, let him try an amidol-meta-bisulphite-cum-pyrogallol-et-ammonia developer.

J. Pike.

CLOUD NEGATIVES, AND HOW TO RECORD THEIR LIGHTING.

[Greenock Camera Club.]

Every one has observed the unfinished appearance of an ordinary photographic print, because of the more or less flat white sky which surmounts it. This is, perhaps, all the more apparent when the subject-matter of the landscape has been well composed and lit. As the artistic sense increases, and we become more familiar with the camera, and acquire some knowledge of the various processes involved in the making of a good negative, we also become more and more convinced that the pictures we have made represent little more than half the picture presented to the eye at the time of exposure; in fact, we begin to see with other photographers, who are art critics as well, that, however beautiful the landscape may otherwise be, it wants that compliment—those beautiful clouds which stretch above the horizon and make the picture a complete whole.

No doubt there are times when the sky is cloudless, and when it would be improper to show clouds, but the reverse is generally the case in this rainy country of ours. Therefore when we strive to produce pictures true to nature, we should not forget the cloud effects with all their delicate tints and tracery. The combination is charming, as all who have examined such photographs will admit. When the clouds are well balanced and well selected for the landscape, a picture, which is otherwise not technically so good, will be more pleasing than another which is better in this respect, but which is surmounted by a white patch of sky. Hence the aim and ambition of most good photographers for some years back has been to introduce clouds into their pictures, thus reproducing scenes from nature in their best and most pleasing aspects.

Unfortunately there is considerable difficulty experienced when we try to represent clouds in our photographs. This is not quite apparent at first sight, but a little consideration will show that it must be so. In developing a landscape negative the sky is always the first to appear, and, if we watch closely, delicate clouds will be seen to make their appearance as development proceeds. Were we to wash and fix the negative at this stage, we would doubtless have a fair representation of the clouds, but unfortunately the rest of the picture would be hopelessly under-exposed. On the other hand, when we carry development to its final stage, so as to bring out all detail in the landscape, we get the sky black without any detail; or, perhaps, as is often the case, somewhat flat and thin. This is due to over-exposure, and cannot well be avoided, except perhaps in strongly lit instantaneous subjects. The fact is that so much more light is reflected from the sky compared with that reflected from an ordinary landscape, that when the latter is properly exposed the former is over-exposed, and *vice versâ:* when the sky is properly exposed, the landscape is under-exposed.

Numerous attempts have been made to overcome this difficulty. Doubtless the best method which has been suggested is to take two negatives of the subject—one exposed for the landscape, and the other for the sky or clouds. The sky is then blocked out from one negative and the landscape from the other; and the print made by exposing twice, once with each negative, due care being taken to ensure that the join of the sky-line will not be observed in the finished print. It sometimes happens, as I have said, that there are no clouds when the negative is taken; more often, that the clouds are wanting in roundness, or sharpness, or variety; or perhaps there are too many, or they may be too dense, or too continuous to form a pleasing combination; and we feel that, if the clouds were just otherwise than they are, we might be tempted to expose two plates.

But another consideration comes in here. The power and endurance of even the enthusiastic amateur is limited, and he objects to carry more than six plates (if the camera be larger than quarter-plate), even if he has more slides to put them in; and so he likes to carry home six landscapes instead of three, as he would do were he to expose two on each view. I know that many photographers would rebel at this dictum, because their motto is to produce a few pictures and do them *well*, rather than a great number only half done. And I am not going to quarrel with these gentlemen; in fact, I sympathise with them thoroughly. At the same time, the amateur whose only opportunity for practising photography is an occasional Saturday afternoon, and a few holidays, must be excused if he objects to expose his plates in this fashion; because, with his limited opportunities—even with the aid of exposure tables and meters—he generally finds that out of six plates he seldom gets more than three or four passable negatives, which would be reduced to one or two were he to devote half his plates to the clouds. The case may be different when one has a roll-holder capable of carrying twenty or thirty films. Then, I would say, make two exposures on each subject when necessary. But we do not all possess roll-holders, and we are at present only considering negatives taken on ordinary glass plates, although what is said with regard to the one is equally applicable to the other.

It has been said that with proper exposure and careful development it *is* possible to obtain clouds and landscape on one plate, but the difficulties are so many that I fear even the "old hands" would shrink from the necessary labour and manipulation. The method which has found most favour, and now generally practised, is that in which negatives of clouds are taken on favourable days independently of the landscape. These negatives are carefully developed and stored away, to be combined with any landscape with which they will harmonise by the masking system and double printing. Of course the negatives of clouds must be lit from the same side as the landscape with which it is to be combined, consequently we must have a stock of such negatives photographed with relation to the lighting in as many ways as we can photograph a landscape. Our stock must also be considerable to enable us to make a selection, and we will require to proceed in a methodical and systematic manner in order to secure it. Some have suggested that this may be done by pointing the camera out of an attic window, and photographing the clouds overhead. Such procedure might be excusable in the case of one confined to a large and smoky city, but most amateurs will prefer to go out into the country in search of cloud subjects. Zenith clouds, even although they may be good as landscapes, are quite unsuitable for combination printing, as they cannot exhibit the same atmospheric and horizon effect to be got from clouds taken in the position which they should occupy in an ordinary landscape photograph.

A good plan is to photograph a beautiful or striking mass of clouds in the open country when one sees it, just as one would a landscape, noting carefully the cardinal direction of the clouds and the sun with relation to the camera at the time of exposure. Or one may set up his camera on a day when the clouds are suitable, and expose several plates, whilst the camera stands in the same position, allowing a certain interval of time to elapse between each exposure, so that there may be a marked difference between each cloudscape. Yet another method is to erect the camera on an elevated position, sufficiently removed from other high ground, and expose one plate in a northerly direction, slewing the camera round, and exposing another in an

easterly direction, and so on round all the points of the compass. Of course it will be necessary, when doing this, to see that only those points are chosen where suitable clouds exist, and that the position of the sun and cloudscape, with relation to the camera, is duly noted for future use.

It is best in taking cloud photographs to make certain that the camera is truly level, and the swing-back standing plumb, to insure that they combine easily with an ordinary landscape. And it is well to take them from an elevated position, so that the horizon line comes down to the middle of the plate, or even lower. The combined print will then show rather less of that dense bank of cloud which overhangs the horizon of many landscapes, an effect which will be enhanced by reason of the horizon line of the landscape coming above the centre of the plate.

With these precautions there is no great difficulty photographing cloudscapes. A small stop must be used with a quick exposure on a slow plate. The development is the same as for an ordinary landscape, taking care not to make the negative too dense. The negatives on the table were taken in the way I have described, some from a window in my house, where the camera remained pointed in one direction, allowing a sufficient interval of time between each exposure to introduce new forms as the clouds rolled past. Others were taken from the top of the Lyle Road by levelling the camera and slewing it round several degrees of arc for each exposure. I cannot say that I have been very successful in securing good effects, but the negatives serve to illustrate my remarks.

If cloud negatives are not difficult to manipulate, the case is different when we try to combine them with a landscape in one print. This is where the difficulties begin. One writer says regarding it (British Journal Almanac, 1888, p. 366, G. Smith), that "the number of prints which are spoiled before a satisfactory print is obtained is only known to those who have had their tempers tried by repeated failures." "One of the greatest difficulties in the printing in of clouds is," he says, "to prevent a sort of halo, or border of light, showing at the junction of the landscape with the sky, or round any object which may project into the sky;" and he goes on to show how this may be avoided by blocking out with opaque water colours, &c., the horizon line and such objects as rise above it. I have not tried this process of combination printing, and cannot speak as to its merits; but I have made several efforts with another process, the results of which fully confirm the remarks just quoted, for my prints were more or less failures. But I must not forget that my remarks to-night are confined to the making of cloud negatives, so I will refer those who wish to prosecute this branch of the subject further to the various excellent articles to be found in the photographic journals and almanacs, assuring them that perseverance in this direction, as in so many others, will doubtless lead to ultimate success.

Meantime we will proceed to consider another factor in taking cloud negatives, at which I have merely hinted, viz., the angular position of the cloudscape with relation to the sun, for cloud negatives would be of little use for combination printing without a proper method of recording the lighting. Photographic authorities and critics have laid down the rule—and with great reason I think—that the clouds to be printed into a landscape must be lit from the same side as the landscape itself. Unless therefore a record is kept of the compass position of the sun and clouds, our negatives will get so mixed that we will not know which to select in order to make a proper combination. In all probability the wrong negative will be chosen, and one of those combinations produced, in which the clouds are lit from the east when the landscape is lit from the west, so offensive to the eye of an artist. All that has been said with regard to the cloudscape is equally important with regard to the landscape when it is intended to print in clouds. Its relation to the sun must also be noted. Now it may be thought from this that I advocate the necessity for the photographer adding a compass to his already numerously stocked kit of accessories, to measure the angle subtended by clouds or landscape and sun. But this is not so. I wish rather to direct attention to a method by which an instrument we all carry in our pockets may be used for this purpose, with almost as much accuracy as a compass. I refer to an ordinary watch. The only condition necessary is that the watch shall be going, and keeping fairly good time. A newspaper paragraph which I read some time ago, was the means of directing my attention to the method of determining the compass points by a watch; and it is so simple that one is surprised it is not more generally known.

At noon the sun is in the meridian, which is due south from Greenwich, and therefore very nearly due south from any place in the British Isles. In the same way midnight is due north, as the sun travels twelve hours while the earth makes half a revolution. There are therefore twenty-four hours in the day. The sun travels one hour of the watch circumference for every two hours of time. Hence, to find the true north by the watch, it is only necessary to note the time in hours counting from midnight and divide by two. If now a line drawn from the centre of the watch through the hour indicated by the quotient be pointed towards the sun—or the sun's position when it is not visible—at the time of observation, twelve on the watch indicates the true north. Thus, suppose we wish to know the north at ten a.m., we divide ten by two and get five. If, now, the watch be placed horizontal, in such a position that an imaginary line projected from the centre through five o'clock points to the sun, twelve o'clock on the watch is due north, and the sun would be in the south-east by south *nearly*.

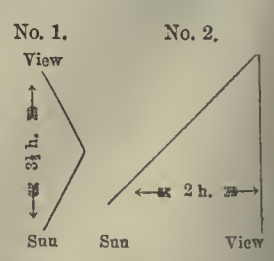
Suppose, again, that it is six p.m., counting from midnight we have eighteen hours, the half of which is nine. Again, placing the watch horizontal, and in such a position that a line radiating from the centre through nine o'clock points to the sun, the hour twelve points to true north, and the sun will be due west. Of course, when one has got the true north, all the other compass points are easily read on the watch face, and we can note at once the cardinal position of sun and cloudscape or landscape, as the case may be.

I hope I have made this plain; it is much more simple to perform than to describe the manipulation, one or two trials will make one quite familiar with it.

We have seen that it is the horizontal angle, subtended by view and sun, which is required, and the finding of the compass points by the watch is only a means to this end. Instead, therefore, of reading the angle in degrees, as might be the case were we working with a compass, and were it necessary to be very accurate in our measurements, it will be found much easier, and sufficiently accurate for all photographic purposes, to read the angle in hours of the watch, thus reducing the measurement to its simplest form.

It is best to note the position of sun and cloudscape with the watch at *the time* the cloud negative is taken, and afterwards, when the negative is developed and dried, to attach a label with all the data recorded thereon for future use. But one should also draw a small diagram on the label, showing the angular position of sun and view *in hours of arc*. This graphic method of recording the lighting makes it particularly easy to select a suitably lit cloudscape for combination with a landscape view, especially when a graphic diagram is also made of the angle subtended by sun and *view*. It is not necessary that the sun and view, and sun and cloudscape should occupy the same *absolute* positions with regard to the horizon. As long as they have the same *relative* positions, the lighting will be right in the finished print. Suppose, for instance, the sun was in the south-west when we photographed the clouds in the south-east, the angular distance would be three hours. Such a cloudscape might be combined with any landscape taken in the east when the sun was in the south, or with one taken in the south when the sun was in the west, because the angular distance between all three is just three hours, and *all are lit from the same side*. It is necessary to emphasise the last remark, for, unless the lighting of the landscape is from the same side as the lighting of the clouds, erroneous combinations will be obtained. For instance, we have seen that, with the sun in the south when a view is taken in the east, the angular distance is just three hours. But it is also three hours when the view is in the west with the sun in the south. And two such landscapes would not *both* combine with the same cloudscape whose arc was three hours, because, whilst one would be properly lit, the other would have clouds and landscape lit from opposite sides, and produce a combination quite unlike anything to be found in Nature. There are, then, right and left-lit cloudscapes for every arc, as there are right and left-lit landscapes, and we must be careful in making our selection that the lighting of both is on the same side.

We have now, I think, gone over most of the ground covered by my subject. I hope I have been able to make myself understood. The operations are all very simple, and any one with a slight knowledge of photography, bestowing a little time and consideration to the details, will soon master them. Let me conclude by referring to the diagram on the blackboard, which will enable me to supplement what I have said regarding angular distances as found by the watch and the graphic method of recording the lighting of clouds and views.



The following are two examples of the method of labelling the negative:—

No. 1.—Cloud negative. Thomas T.C. land plate. 3.40, p.m.; 14 May, 1892. Sun, about S.W.; view, N. by W.

No. 2.—Cloud negative. Paget XXX. plate. 4.5 p.m.; 14 May, 1892. Sun, about S.W. by W.; view, S.

SMALL LANTERNS AND DISSOLVING VIEWS.

[Stereoscopic Club.]

The practicability of reducing the size and diminishing the weight of magic lanterns occupied my attention many years ago. In The British Journal of Photography of May, 1878, I published a description, with illustrations, of two small lanterns which I had constructed. They were very little larger than cigar boxes. The fronts for carrying the objectives were made to disconnect and to pack up inside the bodies when not in use; chimneys were dispensed with in favour of flat tops; they could be used separately as single lanterns, or together side by side or one over the other. The illustrations and descriptions were republished in the *Magic Lantern Manual* of the same year. Thus it will be seen that contracting the size, dispensing with chimneys, and packing the front inside the body, is not the new idea many people suppose it to be. With those little lanterns I have given dozens of successful exhibitions at the Manchester Photographic Society and elsewhere, showing the pictures to twenty feet square.

But for a long time, and down to a few years ago, the biunial lantern —*i.e.*, two lanterns in one body, one over the other—was the prevailing design for so-called high-class lanterns, the object of two lanterns being, as everybody knows, for the production of "dissolving views;" and, in these days of lenses of various foci or long-focus objectives, the biunial lantern has grown into a very heavy, elaborate, and expensive instrument. The triple lantern is a higher development of the biunial, and, by reason of unnecessary elaboration and inconvenience, both triple and biunial lanterns have fallen into disfavour of late years.

There are, however, other uses for a double lantern, or two lanterns, independent of dissolving views, as, for instance, one lantern may be used for the projection of ordinary slides, whilst the other may be employed for the projection of scientific experiments, the lantern microscope, polariscope, &c.

But to return to dissolving views. It has been said that this way of exhibiting improves poor slides, and also helps out a weak lecture, and that it is a very pretty effect; so, if people want dissolving views, they must have them.

What is meant by dissolving views is that one picture fades away, or "dissolves" simultaneously with another picture being made visible—*developing* on the screen.

To produce this effect two lanterns are indispensable; with a single lantern we may have quick-changing carriers, panoramic carriers, or others to produce an out-of-focus effect, or an eclipse, or semi-eclipse, during the change from one picture to the other. But the true dissolving effect is only possible by two lanterns, as has already been said.

Now, it matters not what form these two lanterns take. They may be placed side by side diagonally, as in Dancer's lantern, or one over the other, as a biunial lantern. The idea that a biunial lantern is more conveniently manipulated by one operator may be entirely dispelled. The proper place for a lanternist to stand is at the back of his instrument, and with a properly constructed pair of lanterns everything is within reach, and the opening and closing of side doors and constant adjusting of the objectives for focussing the slides is rendered absolutely unnecessary.

The contrivance for dissolving one picture simultaneously with the developing of the next was originally a "comb" or serrated "fan," worked in front of the objectives by a mechanical arrangement for gradually cutting off the rays from one lantern with the gradual opening of the other lantern.

The late M. Noton, of Manchester, used an iris diaphragm in front of each lens, and by a lever communication one was closed as the other opened. By these arrangements it was necessary to maintain the full light in each lantern during the exhibition.

Mr. Dancer, of Manchester, conceived the idea of turning down the light of one lantern simultaneously with turning it up in the other lantern, and constructed a series of taps actuated by one lever, and immediately after this M. Noton combined the use of these several taps in one plug and body.

Since then the dissolving tap has been slightly modified in design, but it has never been improved; on the contrary, durability and effectiveness have been sacrificed for fine appearances, in some of these fancy-looking taps, six ways are opened and closed in line, on the circumference of a plug three-quarters of an inch in diameter, the object being to get a short plug for compactness, and the very thing that ought not to be. Every mechanic knows that a long plug like a long bearing works better and holds the lubricant. With six ways in so small a circumference there is too little room for tap to keep tight, the slightest dust or grit cuts the plug, and soon it becomes stiff and jambs, or permits the passage of gas from one side to the other, and as a result little explosions, by the mixing of the gas in the tap, are not unfrequent. A well-made dissolving tap ought to be provided with a long plug with the oxygen openings separated from those of the hydrogen by at least an inch in the length of the plug, and between these there ought to be a groove turned in the plug, say one-eighth inch wide and deep, with a hole to correspond in the body of the tap, so that, in case the plug did not fit tight, the gases could not mix, but would escape by the hole in the body; and in this arrangement there are only three openings in the circumference of the plug, therefore more tap and more surface to hold a lubricant. In some of these elaborate-looking taps two bye-passes are provided, one on the oxygen side and another on the coal-gas side; the latter is necessary to maintain a light, but the former serves no purpose whatever, unless it be to increase the expense.

Another method of changing the pictures, and which is a pleasant change from dissolving, is that of one picture rolling up from the bottom displaying another underneath; this is called the roller-curtain effect. In a biunial lantern it is produced by a thin metal shutter passing between the face of the condenser and the picture. The length of this shutter is just in excess of the distance between the optical systems, so that, where the light from one lantern is shut off, the other is open; thus, where the shutter is half way, the sky of the top picture is covered and the sky of the bottom picture is showing on the screen. Of course, where this is used, the light in both lanterns must be at full.

Now it will be seen that when dissolving from one picture to another this curtain shutter must be entirely removed from the lantern, and when we desire to introduce the curtain effect the shutter must be introduced when the top light is turned down; but as soon as the shutter covers the top condenser the light must be turned up, and as the shutter is lowered the picture in the bottom lantern has the appearance of rolling up from the bottom, displaying another under it (shown by the top lantern). At this stage we have the bottom lantern shut off, and the only way to open it is to draw it up again after the picture has been changed. Thus the effect of rolling must always be done *twice* together every time it is used, owing to the fact that the shutter can be removed only from the top.

In a pair of lanterns working side by side a similar effect can be produced; but, instead of rolling up and down, the pictures are introduced sideways, and have the appearance of an unfurling panorama; and, as the shutter may be introduced or withdrawn from either side, the effect may be produced at any time, and for once only and done with, as, for instance, when we wish to skip from one subject to another, or from one part of the country to another.

But the finest effects in changing may be described as a cross between dissolving and the roller curtain. This method was adopted by Mr. Kirnon, the skilful operator to Mr. Rajan, the American lecturer, who visited this country in the early part of the present year.

In the Great Free Trade Hall, Manchester, these lectures had a run of some weeks, and, so far as lantern manipulation, I have never seen that excelled if ever equalled. The screen was thirty-six feet square, and the pictures shown to thirty-three feet square, brilliantly illuminated by limelight.

As seen by the audience, whilst one picture was on the screen another began gradually to develop, and when this was full out the departing picture was not dissolved in the usual way, but, as a friend of mine expressed, it seemed to "fly away," or to be "blown away." Sometimes its departure commenced from the bottom and finished at the top, sometimes it flew away from one corner and then from another, and in a variety of ways it mysteriously vanished; at other times they were quietly and steadily dissolved to the end, and at other times by an instantaneous flash from one to another.

By the kindness of Mr. Rajan and his clever operator I was permitted to see the whole manipulation of these effects.

Two lanterns were used placed side by side, the space between the condenser and the objectives was entirely open, whilst a picture from No. 1 lantern was showing the dissolving tap was turned until the next picture was fully developed; then by a gentle sweep an ordinary lens cap was applied to the back of the objective of No. 1 lantern, and, depending upon the way in which this cap was applied first from one side and then the other, so the picture vanished; the dissolving tap was then turned farther to shut off the light of No. 1 lantern, a new slide introduced, and so the whole goes on with variations at the discretion of the operator.

Now, it will be seen that capping the lens from the back of the objective is very different to the rapid or abrupt cut off by capping in front of the objective. I shall now have pleasure in exhibiting a few effective changes such as I have described.

W. I. Chadwick.

LIGHT IN DARKNESS: INTRODUCING THE STUDY OF PHOTOGRAPHIC METASTASIS.

In 1886, I think, certainly not later, for my own satisfaction, and in order to make sure of my ground in the future, I verified the accuracy of Professor Janssen's sequence of the phases of negative half-tone, positive half-tone, and negative "images" of the sun. Early in the year 1887 I set myself to discover the relation between the times required (= exposures) and the phases produced (= densities 0 (+1), 0·5 (+0·5), 1 (+0), 0·5 (+0·5) and 0 (+1)).

In this I succeeded, but only after making a vast number of experiments, and on January 13, and again on November 16, 1888, in THE BRITISH JOURNAL OF PHOTOGRAPHY, I published, in addition to my general deductions, a typical series of figures (*ex grege gregum*) showing the connexion between the period employed and the phase produced that is between exposure and density. The substance of this article was translated into more than one foreign photographic periodical, and the *Journal of the Photographic Society of India*, in a historical review of the progress of research on solarisation, took special notice of my labours in this field. Later (after May, 1890), I was now and again surprised at coming across, in the *Amateur Photographer* and elsewhere, what I took to be laudatory commentaries, explanatory extensions, and mathematical dissertations on my work. A closer perusal of the articles, however, showed me that while really dealing with my law, they referred to solely the supposed discoveries of investigators other than myself.

Now, although experienced photographers are well acquainted with the more salient characteristics of halation and solarisation, yet are there very few indeed, professional or amateur, who are familiar with the momentary changing details which mark the stages by which, under varied, but for the time being constant, conditions, a negative passes first into a neutral (= no "image" at all), then into a positive, after that into a neutral again, and then once more into a negative. Fewer, still fewer, are they who have timed by the second many thousand prolonged exposures, and photometrically measured the various densities produced in a number of chips of the same plate simultaneously developed by an equal immersion in the same chemical solution.

It is not, then, difficult to see that those who do not read much, or who ignore voluntarily or involuntarily what they have read, form, when they come in contact with a few specimens of halation or solarisation, whether by accident or design, very crude and frequently erroneous impressions.

It is by no means my intention, however, to combat any impression on this subject, either hastily or laboriously deduced, but simply to describe some of the less-known appearances presented by developing plates submitted to different sources of illumination and under various forms of image or screen when abnormally exposed; to expand my original discoveries; and lay special stress upon one or two important facts, which, if observed, have hitherto escaped comment, to suggest a working hypothesis by which much that has remained obscure even to this day may ultimately be theoretically made clear.

HALATION AND SOLARISATION IN GENERAL.

As the present article is primarily put forward for the consideration of experts, it is unnecessary to define either the fuzzy darkening known by the name of "halation," or the clearing of what would naturally be expected to be always the densest portion of the image, to indicate which the terms "solarisation" and "reversal" have in turn been assigned. At the same time, as the ground has been but little trodden, it may be as well to try to guard against obscurity or liability to misapprehension by a preliminary recapitulation of the circumstances under which the salient and best-known features occur before touching upon the modified conditions which render certain details prominently manifest, details probably always present.

In this attempt I will begin with one of the first stages of solarisation, although not yet recognised as such, viz., "halation."

As every one knows, then, halation is most commonly noticed when photographing great or abrupt contrasts of light and shade, and it is habitually assumed that, when present, part of the subject has been "over-exposed," or, which comes to the same thing, disproportionately developed. Figures and groups, in which white and black fabrics are brought together, machinery with strong reflected lights, windows and skies, ere solarisation proper is recognisable, afford the most familiar examples of this "pest," as the practical man calls it. For reasons which will shortly appear, we will not consider self-luminous bodies at present.

Now, generally speaking, halation ordinarily takes the form of a softly fading dark halo surrounding the whole, or extending along one or more of the edges of the image of the brightest part of a natural contrast or series of contrasts. This halo is, as I have just said, dense, but in every-day work is invariably, or almost invariably, less dense than the portion of the image with which its darkest "edge" is in contact. It is in this respect, or in this aspect, more particularly that it has been considered by those who have attempted to trace the course of the effect, propound a theoretical explanation, or propose a cure. To the best of my knowledge, only two causes have as yet been advanced. One of these—to wit, reflection from the back surface of the glass support—is that which most obtains: and, while I grant that this is frequently a potent factor, I hold that it is an insufficient explanation in so far as halation, and even reversal, occurs in films exposed and developed on white and even red paper. The other hypothesis—offered first, I believe, by Captain Abney—is that the effect is due to the scattering of the light by reflection from the individual agglomerated particles of silver haloid constituting, together with the suspending vehicle, a translucent film. I devised and carried out, however, an experiment which proves that this action, if existing at all, has an almost imperceptible effect.

Beyond these two formulated hypotheses regarding the nature of halation I known of none. It is true, however, that the trained scientist who dabbles more or less in photography talks equally learnedly and vaguely of "a molecular action which precedes the chemical one," and I for long held—and I am not sure that I do not still hold—that the alternate power to attract and repel the metal supplied from the solution of silver salt thrown down by the depositor was due to an electrical action and to a form of electrical polarisation. Suffice it to say here, however, that as yet halation has been treated as something distinct from solarisation.

Solarisation is still more seldom encountered, still less understood, if that is possible, than halation. I have read, here and there, at rare intervals, summaries of all we are supposed to know about it, and for all the information imparted, either historically or scientifically, they might as well have never been written.

In 1839 Fyfe, Lassaigne, Talbot, Herschel, and Hunt observed, in the words of the last named, "a singular property in the hydriodate of postash of again whitening the paper darkened by exposure, and also that the bleaching process was very much accelerated by the action of light." . . . . "The most extraordinary character of the hydriodic salts is, that a very slight difference in the strength of the solutions, in the composition of the photographic paper, or in the character of the incident light, produces totally opposite effects; in the one case the paper is rapidly whitened, in the other a deep blackness is produced almost as rapidly. Sometimes these opposing actions are in equilibrium, and then the paper continues for a long time perfectly insensible."

Now, although this property forms the basis of the production of positive images in silver-salt photography, it has only an indirect bearing on solarisation, although, much later, Abney employed the same principle, namely, that of dosing a darkened silver salt, insolating it, and obtaining a positive by this means, argued therefrom as to the nature of true solarisation proper.

Although the term solarisation was at first simply confined to actions analogous to the partial *darkening* of skies in Daguerreotype landscape, and in no wise implied complete reversal, yet one of a series of experiments, made by Shaw and Percy with the object of seeing whether the sensitiveness of an exposed Daguerreotype was restored by the action of mixed vapours of iodine and bromine, abundantly proves that complete reversal was obtainable by the development with mercurial vapour under circumstances entirely in accord with the phenomena of to-day, in which the period of exposure is only variable. I copy the paragraph *in extenso* from Hunt's *Photography*, second edition, pp. 194, 195.

"A prepared plate was exposed to light and afterwards to the mixed vapour; mercurial vapour was found to have no effect upon it; the plate was then partly covered with a metallic screen, fixed close to, but not in contact with it, and the whole was exposed to light. On placing the plate in the mercury box, a broad white band, nearly corresponding to the edge of the defended part, made its appearance; the whole of the defended part (excepting the band in question) was unaffected, and the exposed part exhibited very little change. By a careful examination of the plate after it was removed from the mercury box, the white band in the middle appeared to be produced by the feeble light which had passed under the edge of the metal plate which had screened the light from part of the prepared surface; *and the very dark, and apparently unaltered appearance of the exposed part, was occasioned by an excess of action, for mercury was found to have condensed on that part in large quantities, and to have produced the dark lead colour which is commonly called solarisation; but which effect, in the case in question, was so excessive, that the colour of the part on which mercury had condensed differed but very slightly from that on which no light had fallen.* It was now evident that *the apparent absence of effect* in the last experiment *was in reality* occasioned by *an excess of action;* and by repeating that experiment and making the time of the second exposure to light much shorter than before, the plate

assumed, under the action of mercury, an intense and beautiful whiteness." [The italics here are mine.]

For the next fifteen years the subject seems to have attracted but little attention, but 1855–6–7–8 were fertile in observations on the "Alternating Action of Light" (Hardwich, *Journal of Photographic Society*, vol. ii. p. 211); the "Reversed Action of Light" (Jackson, *Ibid.*, vol. iv. p. 76); the "Reversed Action of Light" (Hardwich, *Ibid.*, p. 82); "Reversed Action of Light" (Craddock, *Ibid.*, p. 144); "Reversed Action of Light" (——— *Photographic Notes*, vol. iii. p. 92); after which, to leave my note-book and quote from memory, the papers of outstanding importance have been, first, that of Prof. Janssen, who, as I have already more than once stated, was the first to give the true order in which the phases followed each other, and who was also the first to establish the fact, that in addition to the neutrals other phases occurred and recurred; and second, that published by myself in 1888, in which, after showing in the first, second, and third paragraphs that the superficial degradation first formed by light, either on ordinary silver paper or on a gelatine dry-plate, forms an obstacle to the penetration of the light which falls upon the film afterwards, a degradation palpable after fixing; in paragraph D. I said: "If the normal be produced with an exposure x, and the first neutral (invisible) with an exposure nx, then the first reversal will be obtained with an exposure n^2x, the second neutral with an exposure n^3x, the second normal with an exposure n^4x, and, presumably, so on, *e.g.*:—

Normal	5 seconds
Neutral	90 „
Reversal	1,620 „
Second Neutral	29,100 „
Second Normal	524,880 „

which is, *I think*, equivalent to stating—

That the numerical expression of the given density (1·0,0·5,0·0,0·5, 1·0) corresponds *in a certain manner* to the number expressing the exposure.

This, *I again think*, is equivalent to saying that "the logarithm of a number is the index or exponent of the power, to which a given constant base or root must be involved, to be equal to that number."

And either expression of my law, *I again venture to think*, is precisely the same thing as saying that "the densities are proportional to the logarithms of the exposures." This last quotation is taken from Messrs. Hurter & Driffield's paper, published in the *Journal of Chemical Industry*, May 20, 1890.

I would here remark that, as I acknowledged at the time, the numbers I employed to express the exposures corresponding to the given densities dependant upon them were not directly found by experiment, but were deduced from a mass of more or less conflicting testimony.

My figures were, I acknowledge, deduced, not found for me, mechanically by a machine, and were given by myself purely and simply to convey my impression as to what the *exact* relationship between time of exposure and density of deposit should be, bearing in mind, as I pointed out, that there was always a slight excess of density or decrease of attractive or repulsive power as estimated by the exposure, due to the printed-out degradation of the film, for which allowance had always to be made.

While this determination of the sequence, and the periodicity of the sequence, must of necessity be put prominently forward as of special practical or theoretical value, it must not be forgotten that much more light was cast upon this obscure question, among which may be cited as pre-eminent Abney's previous approximation to the sequence, his experiments—aiming, however, at an explanation of the phenomena of halation, defined as distinct from solarisation—with apertures of different shapes, his experiments on and the evidence led by the spectroscope as to the refrangibility of the rays producing reversal.

Neither must I omit my own independent experiments verifying or denying the truth of Captain Abney's conclusions, nor those in which I demonstrated that *thio*-sulphate of sodium added in excess to a ferrous oxalate developer produced reversals with normal or under exposures. Colonel Waterhouse's discovery that *thio*-sinnamine tended to produce reversals with exposures of similar duration, and his far more crucial researches on the evidence, led by the galvanometer on reversed electro-magnetic currents, induced by reversing exposures, must not be forgotten.

This latter form of experiment, I may say, I have over and over again repeated, and have invariably confirmed the reliability of Colonel Waterhouse's results. At the same time, I confess that my researches in this direction have been only partially published, and that my results remain unclassified. HUGH BRENNER.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

In considering and in recording the results of examinations, it has been found convenient to give more exact meanings to certain expressions than have as yet been assigned to them. The following definitions have therefore been adopted at Kew:—

A narrow-angle lens means one covering effectively not more than 35°.

A medium-angle lens means one covering between 35° and 55°.

A wide-angle lens means one covering between 55° and 75°.

An extra wide-angle lens means one covering more than 75°.

With regard to the wording of the "General Remarks" in the certificate, it should be remembered that the lens is judged entirely with reference to a plate of named sized; the lens is therefore classed as above by the angle of field which is given as the last item but one in test No. 10. If the same lens is examined for plates of different sizes, the certificates would be worded differently in each case.

The C.I. No. of a stop means the number which indicates the intensity of illumination produced by it on the plate according to the system proposed at the International Photographic Congress of 1889

The *largest normal stop* means the largest stop that can be used with the lens so as to produce definition up to a selected standard of excellence all over a plate of given size, the objects whose images are seen being all equally distant.

A slow lens means one of which the largest normal stop has a less diameter than has C.I. No. 6.

A moderately rapid lens is one of which the largest normal stop is C.I No. 6, or larger than that size and less than C.I. No. 2.

A rapid lens is one of which the largest normal stop is C.I. No. 2, or larger than that size and less than C.I. 2/3.

An extra rapid lens is one of which the largest normal stop is C.I. No. 2/3, or larger than that size.

For convenience of reference, these definitions will in future accompany the certificate, probably in the form of additional notes.

No doubt most lenses are supplied with stops larger than the ones here called the largest normal stops, even if it is not intended to use smaller plates than those under consideration; this is, of course, very right, for in many cases the photographer will be willing to sacrifice the definition near the edge of the plate for the sake of increased rapidity.

It now remains to be shown in what way the above certificate of examination would be useful to the practical photographer, who has sent his lens to Kew for the purpose of being tested. It may, we think, be assumed that he wants answers to the three following questions:—1st, Is the lens a good one? 2ndly, Does it properly cover the plate of the named size? And 3rdly, What exposure must be given when using the different stops.

With regard to the two first questions, the result of the examination is recorded in such a way that he may either rely on the "General Remarks," or he may form an independent judgment from the results of the tests.

In order to decide himself, from the records in the certificate, whether the lens is, generally speaking, a good one, he should first look to test No. 13 to see if the definition in the centre of the plate with the largest stop is "excellent," as should always be the case; he should then consider test No. 15, by which he will see what are the faults introduced by the lens not being properly corrected for chromatic aberration. With regard to the second question—that is to say, when considering whether the plate he intends to use is properly covered or not, he should chiefly look to the results recorded under test No. 13, where is given the size of stop or the rapidity of the lens for a given standard of definition up to the edge of the plate. If the definition at the centre is "excellent," then any want of definition at the margin will be chiefly due to curvature of the focal surface or to astigmatism, and therefore the results of tests Nos. 12 and 16 should be considered at the same time as test No. 13. He must also look carefully to the result of test No. 14, which shows the maximum distortion produced in the image. It will depend for what class of work the lens is to be used whether he should consider the amount of curvature in the image of a straight line near the edge of the plate, which will be there indicated, is objectionable or not.

The "General Remarks" are recorded as the result of exactly similar considerations to those discussed above, the experience gained by the examination of lenses of undoubted quality giving an idea of what standard of excellence should be required.

With regard to the third question, as to the exposure to be given with the different stops, it may be hoped before long that the C.I. numbering will be generally adopted by all practical photographers, in which case the results of test No. 9 will give the information required.

* Continued from page 697.

In many works on photography, the view is expressed that the practical photographer also wishes to know from what point on his lens he should measure or adjust the distance of any object so that, by reference to tables, he can obtain definite enlargements or reductions; this is, in fact, urging that the position of the principal planes should be marked on the mounting of all lenses. According to our experience, this is a want in reality very seldom felt in practice. The tables are, no doubt, sometimes used to get approximate results, the fine adjustment of scale being afterwards done by measurements on the ground glass; but if the slot between the two lenses of a doublet is used as the point from which the measurements of distance are made, the results will be quite near enough to the truth to serve as a first adjustment, and for this purpose nothing will be gained by marking the exact position of the principal planes; it should, however, be stated that the omission to mark them is merely made in consequence of the necessity felt of minimising, in every possible direction, the time spent in the examination.

Each test to which the lens is subjected will now be described in detail, together with such discussion as to the reason for its adoption as may appear necessary.

The first four headings of the certificate deal with the numbering of the lens, the maker's name, the size of plate for which the lens is to be examined, &c., and as these do not form part of the results of the examination, no remarks are necessary with regard to them.

5. Number of Reflecting Surfaces.

In most cases the number of reflecting surfaces of glass is known at once from the type of lens, but, if in doubt, a simple experiment will settle the point; the room is darkened, and the reflection of a lamp is observed in the lenses; each of the surfaces of the lenses will give one direct reflected image, and the number can thus easily be counted. The amount of light which reaches the photographic plate decreases with an increased number of lenses, because of this reflection, and this circumstance should not be forgotten in estimating the suitability of a lens for any special purpose. Surfaces merely separated by Canada balsam reflect little light, and need not be considered from this point of view.

6. Centering in Mount.

Two different errors might be described under this heading: either (1) the optical axis of a perfect lens may not coincide with the axis of the mounting, or (2) the axes of the different lenses of a doublet or triplet may not all be in the same straight line. As to the first of these errors, we believe it would never be sufficient to have any appreciable effect on the practical value of a lens, and therefore no test for it is considered necessary. With regard to the second error, Wollaston's test is the only one applied; this consists of looking at the flame of a lamp or candle *through* a compound lens, and noting if all the different images of the light as seen by successive reflections from the surfaces of the glass can be brought into line by a suitable movement of the whole lens, which should be the case if the component lenses are arranged about a common axis.

It may be remarked that the nodal points may be shifted away from the mechanical axis of the lens in consequence of either of the above-mentioned errors, and also, on the other hand, that the second error may exist—that the axes of the component lenses of a doublet may not be coincident—and yet one or both of the nodal points may conceivably be found on the mechanical axis of the mounting; it follows, therefore, that to estimate the distance between the nodal points and the mechanical axis, which has been suggested as a means of detecting any want of centering, does not answer that purpose very well.

7. Visible Defects, such as Striæ, Veins, Feathers, &c.

Under this heading any faults detected by a careful inspection are given.

LEONARD DARWIN, Major R.E.

[To be continued.]

A PHOTOGRAPHIC GUIDE BOOK.

A RECENT journey amongst a few of the central Italian cities has given me some experiences which I feel disposed to turn to the profit of the craft, professional or amateur, and the practical nursing of which to maturity I would recommend to the Camera Club, which has the best appliances for its actuation. It is the editing of a guide to photographers who wish to profit by the short and sometimes hurried visits they may make to the picturesque cities all over the world. There will always be a great pleasure in the hunting out picturesque bits for the sake merely of their picturesqueness, and the taste of men, and women, will differ as to point of view and attractiveness of subject, but there are certain points on which the agreement will practically be complete. These are on the value of historical monuments, celebrated buildings and localities, &c., &c., and these are in most cases to be best seen under aspects which do not depend so much on the taste of the photographer as on the points of the compass.

My plan is this, Let every tourist-photographer who has made a stay in any attractive city, likely to be much visited by his *confrères* make a careful and exhaustive study of the monuments and subjects in it, and note the point of view and hour of the day which show them to the best advantage, if possible to be accompanied by a small map of the city with the monuments indicated, the hour of the day at which the light gives it the best effect, and shows best the character of the architecture. Let the Camera Club appoint an editing committee whose business it shall be to collect and examine these reports and amending one by another if feasible, make a thoroughly practical guide to the tourist which shall save him the trouble of examining the cities included at all times of the day and at more or less varied seasons of the year, and in case of hurried and necessarily limited visits, enable him to use his time with the greatest economy. Like Baedeker or Murray, this should be overhauled and added to as occasion offers and contributions permit, from time to time, and new editions issued as may be needed.

I offer an example, not as a specimen of what the plan ought to be so much as to show the direction of the instructions, because the city which I use as illustration is one I have not been long enough in to do all that it needed, neither having been in it at the best season. In fact, I was too late in the year to get some of the most important monuments, and these I indicate by general knowledge of what the situation demands. It is a sketch of a section of the book.

PERUGIA.

On the railway between Florence and Rome *viâ* Terontola. Hotels recommended, Grande Bretagne, Albergo di Belle Arti, Grand Hotel di Perouse, dearer and much resorted to by season visitors. Objects of photographic interest: The great gate, locally known as the Etruscan gate, one of the ancient gates of the city, and the only one in a state approaching that of the Etruscan epoch. It is only to be taken with any effect of sunlight in the early morning of the long days of June and July, as it faces the north and the surrounding buildings interfere with the morning light. In the month of September the light only falls on it from 7 a.m. to 7.30, but too red to give any effect of light and shade even with orthochromatic plates. Palazzo Communale, the ancient town-hall on the principal square of the city; two views, one from the north-east, only to be got in the morning light and not later than August, when it is available about 7–8 a.m., and the other of the principal façade on the main street of the city, comes into the best light about 10–12 a.m. The fountain of Fra Benvegnati in the main square is best at about 2 p.m. The Church of St. Angelo (an ancient temple turned into a church) is most available at 8-10 at any season, and the gate of St. Angelo, close by, a fine example of the military architecture of the 12th-13th centuries, is to be taken in the afternoon of any month, 3 to 4. The church of St. Bernardino, one of the most important works of Agostino di Duccio, should be taken in the hours between 10 a.m. and noon. There is a most interesting view of a part of the city to be taken from the viaduct which crosses the valley between the University and St. Agostino, looking toward the south-west, with the ancient gate of the city (restored in the middle ages and with a Gothic arch) up a long flight of steps; at the right is seen a long piece of the Etruscan walls of the city. The Porta Eburnea offers a picturesque as well as archæological interesting subject in the morning, about ten o'clock, from the street below the terrace in front of the Grand Hotel di Perouse. The Porta Marcia, a gate removed from its ancient position by San Gallo to make room for the citadel (now demolished) comes into light in the afternoon, 2 to 4.

To the east of the city, from various points beyond the walls there is an interesting view of the great plain of the upper Tiber with Assisi in the distance, to be taken in the late afternoon of very clear days. The upper Tiber presents some most picturesque points lower down, in the vicinity of the first station towards Assisi, Ponte S. Giovanni and from the villages of Ceppi, Bicocca, Fratta, &c., and a beautiful view of the valley of the Tiber is seen from Sta. Petronilla, two miles beyond Perugia on the road to Umbertide.

This is not intended to exhaust the example I have taken, as there are many things of interest to the photographer in Perugia, but it will serve to illustrate my idea. With such a guide in hand the tourist goes at once to the points which he may be most interested in, at the proper hours of the day, and studies his point of view and effect to suit his own taste. He knows when the sun illuminates the subject he wants, and, if by chance he has but limited time to give to the place,

he makes the most of it. In short, it would do for him what Baedeker does for the hurried tourist, saves him the trouble of exploring the locality without a previous idea of what he may find of interest, and, if he must hurry, enables him to do so with the least loss of his opportunities.

W. J. STILLMAN.

Rome, October 27, 1892.

Our Editorial Table.

VARIOUS PRINTING PAPERS.

MR. OTTO SCHÖLZIG, 31, Binfield-road, S.W., sends samples of a new paper he is about to bring into the market under the name of Schölzig's enamel paper. It is a salted, hardened, gelatinised paper, to be sensitised by the photographer himself, and toned and fixed in the usual manner. The sheet is 20×24 inches. The samples sent are tinted, one sheet a mauve and the other rose, both very delicate.

A SPECIMEN of double albumenised, sensitised paper, received from Mr. W. Webber, Bristol, printed with a fair degree of rapidity, and took a good tone in the acetate toning bath.

CELLOIDIN paper, a Continental production, has been introduced into this country by Messrs. A. & M. Zimmerman, Cross-lane, St. Mary-at-Hill, E.C. The printing process is the same as that for albumenised paper. The toning and fixing are recommended to proceed simultaneously, a formula for the combined bath being given.

HARTLEY'S CELLULOID DEAD BLACK.

THE Anglo-American Varnish Company, Birmingham, has submitted a sample of the above black varnish, which may be applied cold to wood, leather, or metal. It dries dead, and adheres well.

METAL LANTERN-SLIDE BINDING STRIPS.

WE have received from the Photographic Enterprise Company, Birmingham, specimens of their "Enterprise" lantern-slide binding strips. They consist of a strip of tin, having the edges turned over, and capable of bending and holding together the slide, the matt, and the covering glass. They will be useful in the extemporising of mounts.

NOXINOL AND THIOTONE.

THESE preparations are introduced by G. Wright & Co., Hopwood, Lancashire. By the addition of a little of the former to the developing solution, it assumes a non-actinic colour of such a quality as to prevent freedom from such fogging as might result from developing plates in tents, or other places where it is possible there may be such a degree of light as would cause fog. Thiotone (for which a patent has been applied) is a toning solution for producing rich, warm tones on gelatino-chloride printing-out papers.

THE POLYTECHNIC INSTITUTION.—The following lectures commence on November 8:—*Art in Relation to Photography, with Examples.* Six weeks' course. Mr. Valentine Blanchard. *Technique and Practice of Studio, Landscape, and Architectural Photography, with Examples and Demonstrations.* Six months' course. Mr. Howard Farmer. *Science and Technique of Photography* (City Guild's programme). Mr. A. W. Dollond. The Practical Classes commence on November 8, and comprise Studio Posing and Lighting, Studio Posing and Lighting (Electric Light), Finishing Enlargements in Black and White, Wet Collodion (for Photo-Mechanical Processes, Copying, &c.), Photo-Gravure, Enlarging, Lantern Slides and Lantern Work, Collotype, Silver, Carbon and Platinotype Printing, Retouching, Photo-Lithography and Zinc Process Work. Prospectus and syllabus of either of above classes on application to Mr. Robert Mitchell, Secretary, at the Institution, 307, Regent-street. The programme, it will be seen, traverses practically the whole field of photography, and to any one in search of instruction provides all the opportunities needed. The Polytechnic has been so far very successful in teaching photography, and doubtless will continue so.

THE Photographic Society of Great Britain had 1213 visitors to the Exhibition last week, making a total of 7490 since it opened to the public. The Lantern Evenings especially have increased in popularity this year, and, with the single exception of the Inaugural Exhibition, up to the present this year's heads the list.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

PATENTS COMPLETED.

IMPROVEMENTS IN CLAMPS OR CLIPS FOR USE IN PHOTOGRAPHIC COPYING PROCESSES.

(A Communication by Alois Delng, Munich, Bavaria.)

No. 865. WILLIAM PHILLIPS THOMPSON, F.C.S., M.I.M.E., 6, Lord-street, Liverpool, and 6, Bank-street, Manchester, Lancashire, and 323, High Holborn, Middlesex.—*October* 8, 1892.

THE clamps or clips employed in copying processes in photography have the drawback of hindering the passage of the light at the points where they grip or touch the plate to which they are applied. The consequences resulting therefrom have been long known to every practical man.

This invention has for its object to provide a clamp or clip which, when used in photographic copying processes, will produce as little injurious a shadow as possible. This is attained by constructing the upper arm of the clamp or clip in a peculiar manner, and more particularly by causing the same to come in contact with the plate at one point only.

The invention may be carried ont in various ways. For instance, the clamp or clip may consist of a stirrup springing outwards, which is formed either of a sheet spring or a wire. The lower jaw of the clamp or clip is attached to the upper arm of the stirrup, and is bent off at right angles downwards, whilst the upper jaw is attached to the lower arm of the stirrup, and is bent upwards. The upper jaw is, as already previously mentioned, constructed in such a way that it stands as little as possible in the way of the action of the light, and only grips the plate above at one point. It is, therefore, preferably constructed of wire, which stands vertically on the plate, bends round further above, and extends downwards, where it is attached to the lower arm of the stirrup. The lower jaw may have a correspondingly broader surface, or may come in contact with the under part of the plate at only two points. The stirrup with its two arms may be constructed ont of one piece of wire, on which suitable finger plates, for convenience of handling the clamp or clip, are soldered or otherwise suitably fastened.

In another pattern of clamp or clip two plates may be connected by a spiral spring, and acting with a spring pressure against each other, something after the fashion of a clothes peg, the upper one of which receives the clamp or clip jaw, hereinbefore described.

As this latter stands as upright as possible on the plate, and only bends further upwards, it becomes possible that the rays of light will fall during the entire duration of the exposure on all points of the plate with the exception of the points of contact of the upper clamp jaw.

APPARATUS FOR DEVELOPING, FIXING, AND WASHING PHOTOGRAPHS.

No. 19,471. JULIUS WAGNER and GEORGE BIEDIG, both of Zeitzerstrasse, 27, Leipzig, German Empire.—*October* 8, 1892.

OUR invention has for its object to provide a box or tray which serves not only to receive the developing or fixing liquid, but which is constructed in such a manner that the negative may be securely held in the box and easily examined or observed from both sides, without pouring out the liquid and without admitting the full daylight.

For this purpose we form the developing box of two principal parts, namely the lower part, serving to receive the developing liquid, and the upper part, serving to receive the negative, the two parts being separated from each other by a grate or other suitable means, and the whole having preferably the shape of a shallow rectangular trough or box placed upright, that is, on one of its narrow sides, and closed on all sides except at the top, which is provided with a hermetically closing cover.

The front and back of the upper part of the box are made of red glass or provided with red glass windows, through which the negative can be observed when it is not surrounded by the developing liquid. The liquid is admitted through a funnel placed at the top of the box and communicating with the lower part of the box through a vertical pipe situated along one of its narrow sides. A draw-off cock and short pipe placed at the bottom of the box serve to discharge the spent liquid.

To develop a negative by means of this apparatus, we proceed as follows:—

After removal of the cover, the negative is introduced into the box so that it rests with the lower edge upon the grate mentioned above, while the top is held by the cover (which is now closed) and a narrow guide slot.

The developing liquid is now poured into the funnel, the feed-pipe leading down from the funnel is closed by a stopcock, and the liquid is brought in contact with the negative by holding the box upside down, horizontally or in any other suitable position. In order to observe how far the image has been developed, the box is placed upright, so that the liquid runs into the lower part, while the negative remains in the upper part, so that it can be easily examined through the windows.

To many of those who are conversant with the early annals of gelatine dry plates, it will be interesting to know that Mr. Peter Mandsley is to revisit this country early in November. He has long been resident in Rochester, New York, and has not been making dry plates for several years, although, as a landscape and general photographer, he has been a user of them.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
November 7.....	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 7.....	Halifax Camera Club.....	
,, 7.....	Peterborough	Museum, Minster Precincts.
,, 7.....	Richmond	Greyhound Hotel, Richmond.
,, 7.....	South London	Hanover Hall, Hanover-park, S.E.
,, 7.....	Stereoscopic Club	Brooklands Hotel, Brooklands.
,, 8.....	Derby	Smith's Restaurant, Victoria-st.
,, 8.....	Great Britain	50, Great Russell-st. Bloomsbury.
,, 8.....	Manchester Amateur	Lecture Hall, Athenæum.
,, 8.....	Newcastle-on-Tyne & N.Counties	Mosley-st. Café, Newcastle-on-Tyne.
,, 8.....	Paisley	Committee Rm., Free Lib. & Museum
,, 8	Stockton	Masonic Court, High-street.
,, 9.....	Ipswich	Art Gallery, Ipswich.
,, 9.....	Leicester and Leicestershire ..	Mayor's Parlour, Old Town Hall.
,, 9.....	Munster	School of Art, Nelson-place, Cork.
,, 9.....	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 9.....	Putney	High-street, Putney.
,, 9.....	Reading	
,, 9.....	Stockport	Mechanics' Institute, Stockport.
,, 10.....	Birkenhead Photo. Asso. (An.).	Association Rooms, Price-street.
,, 10.....	Birmingham	Lecture Room, Midland Institute.
,, 10.....	Bradford Photo. Society	50, Godwin-street, Bradford.
,, 10.....	Camera Club	Charing-cross-road, W.C.
,, 10.....	Cheltenham	
,, 10.....	Hackney	206, Mare-street, Hackney.
,, 10.....	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 10.....	Manchester Photo. Society	36, George-street, Manchester.
,, 10.....	North Kent	Gravesend.
,, 10.....	Oldham	The Lyceum, Union-st., Oldham.
,, 11.....	Cardiff (Annual)	
,, 11.....	Holborn	
,, 11.....	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 11.....	Maidstone	"The Palace," Maidstone.
,, 11.....	West London.....	Chiswick School of Art, Chiswick.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 27, Mr. R. Beckett in the chair.—Messrs. R. Bartlett and H. Bremner were elected members of the Association.

QUESTIONS.

The following question from the box was read: "A lantern is fitted with twelve-inch Petzval objective and four and a quarter inch condensers, meniscus (near the light), and plano-convex. A flat field cannot be obtained. Either there is a ragged edge on the disc, or a dark ring round the centre. Making the meniscus more concave has been tried, but does not improve it to an appreciable extent. What is the remedy?"

It was suggested that the condenser was unsuitable, and that another had better be obtained. No other "remedy" was given.

Question No. 2 inquired for a means of getting rid of the yellow stain remaining on gelatino-chloride paper after the combined toning and fixing bath and alum solution had been used, and was deferred to another meeting.

TEMPERATURE AND DEVELOPMENT.

Mr. A. COWAN stated that, the rapidity of a certain plate having been called into question, he had exposed two pieces of one of the plates side by side behind a series of tints, and had developed them in the same solution, but at different temperatures—58° in one case, 70° in the other. The former then only appeared to be a fifth or sixth of the rapidity it ought to be, development occupying exactly the same time in both cases. Three pieces had also been identically exposed and developed, one for ten minutes at 58°, one for two and a half minutes at the same temperature, and one for two and a half minutes at 70°. The first and third were practically identical in regard to the number of tints brought out. Mr. Cowan had confirmed the effects of temperature on development by exposing several plates and developing the first one, which had the appearance of being under-exposed. Upon testing the water, he found it to be 54°; on warming it up to the proper temperature—70° (which, he said, was conveniently obtained in either summer or winter)—the remaining three plates came up all right.

DO PLATES LOSE SENSITIVENESS IN VOLCANIC REGIONS?

Mr. J. WEIR BROWN presented a communication from a friend who had been travelling in Costa Rica. At an altitude of 4000 feet above the sea level he had used films of 18° and 24° (Warnerke) sensitiveness respectively, in a good light at *f*-11, with an instantaneous exposure, found that he was under-exposing. A professional photographer there told him that he had to give longer exposures after plates had been in the country three weeks, which he attributed to the sulphur in the air, sufficient of this being present to at times blacken plates. Mr. WEIR BROWN quoted Mr. Howard Farmer's experience in Egypt (as given at a previous meeting of the Association) of having found his pictures under-exposed in the shadows, notwithstanding the bright light. It had also been suggested that, at a high altitude, a pure blue sky was non-actinic.

Mr. T. BOLAS observed that the presence of carbon dioxide would weaken the actinic power of the light.

Mr. W. E. DEBENHAM thought the particulars given might be the result of "mistaken observation."

Mr. A. HADDON said the matter could be tested in the laboratory, a film being exposed to the action of sulphuretted hydrogen, and then developed side by side with one that had not been treated with H_2S. He thought iridescence due to sulphur in the air.

The CHAIRMAN said iridescence on the negative could be removed by means of a tuft of cotton-wool and a little methylated spirit.

A passage from a work by the late Robert Hunt having been quoted at a previous meeting to the effect that, in the presence of a relatively large amount of red light, a small amount of white light was inactive on a sensitive surface, the following experiment was undertaken:—A sensitive plate, secured to the blackboard, was, in darkness, subjected to the action of three kinds of dark-room glass—red, deep orange, and ordinary ruby—projected from the upper lantern of a biunial, the white light, cut down by means of a diaphragm, proceeding from the lower lantern. Three different exposures were made, and on development it was found that the first plate was much over-exposed, but in the other two it was seen by the developed images that in no case did either of the varieties of the "red lights" diminish the effect of the white on the plate.

After further discussion the meeting closed.

Hackney Photographic Society.—October 25, Mr. F. Houghton presiding.—Mr. GOSLING asked for experience of gelatino-chloride paper. The CHAIRMAN was rather in favour of over-printing and long toning. Mr. BECKETT said plenty of gold should be used. A discussion then ensued on the new platinum paper. Mr. GRANT found it required more printing than the hot bath. Mr. GOSLING asked for a better mountant than starch for printing out paper prints. Mr. BARKER advised Houghton's "Excelsior," as being always ready for use. Mr. R. BECKETT then proceeded to give a demonstration on flashlight photography. He did not recommend such explosives as chlorate potash, as it was apt to cause the sitter to start. Portraiture was not eminently adapted for flashlight; it did not come near electric light. For interiors, such as churches, it was quite at home, so to speak, and for caves and subterranean matters invaluable. Its defects were that it was apt to cause people to blink their eyes; another was getting rid of the smoke; and, again, there were generally unburnt particles flying about, which would grind into carpets, &c. Demonstrations were then given, and the lecturer showed the way of placing lamps, using two pairs of steps, reflector, &c. The lights must be placed so that there was softness in the shadows, and reflections in the eyes avoided. Mr. DANDO had seen good pictures obtained by using platinotype lamps. Mr. Hudson showed his flash-lamp (continuous). He used magnesium powder, which was blown through the centre of a spirit lamp, and gave a continuous and powerful light.

Aldenham Institute Camera Club.—October 25, Mr. W. Vere Mingard presiding.—Mr. Allan Hair gave the second of a series of lectures on *The Eye as a Camera Obscura*. The lecturer briefly recapitulated the substance of his former address, and then proceeded to compare the receptive power of the retina with that of the sensitive plate in the camera. A very interesting account of the "visual purple" theory, tracing optical impression on the retina to the chemical decomposition of this substance by light, seemed to show a still closer likeness to the photographic process; but, when the lecturer stated that the eyes of the dove and the bat possessed no "visual purple," and that the yellow spot of the human eye was without it, the theory fell hopelessly. The subjects of distinctness and persistence of vision were next discussed, and the lecturer finished with a theory respecting the ability of the eye to appreciate colour, and its bearing on colour photography.

Harlesden (Willesden) Photographic Society.—October 25, Mr. J. Naylor in the chair.—Mr. Woodbury gave a demonstration on *Gelatino-chloride Printing Processes*. The Secretary handed round some samples of the new Paget prize lantern plates, kindly sent by the Company, and instructed the members in the methods of making lantern slides by contact and reduction. The next meeting, on the 22nd inst., will be a Lantern Evening.

West London Photographic Society (with which is amalgamated the Chiswick Camera Club).—October 27, Mr. W. A. Brown in the chair.—The CHAIRMAN introduced to the meeting the new President, Mr. J. A. Hodges, who then proceeded to deliver his inaugural address. After referring to the valuable services of the late President, and having given a word of welcome to the Chiswick Camera Club (now amalgamated with this Society), Mr. HODGES suggested that more useful results would ensue if members more generally joined in the discussions on technical papers. He then suggested that the Society might undertake a photographic survey of western London, and, after some advice to beginners to strike out a line of work for themselves and not to dabble in many processes, Mr. HODGES enumerated some of the most important photographic inventions of the year—viz., the photo-telescopic and concentric lenses, Van der Weyde's device for correcting exaggerations in portraiture, Willis's improvements in the platinum process, the Sandell plate, and improvements in celluloid films.

Richmond Camera Club.—October 24, the President in the chair.—Mr. G. Ardaseer showed Cowan's lantern-slide printing frame, a most convenient piece of apparatus for making slides by contact, and very suitable for collodio-bromide plates, as with it there is little risk of damaging the film by abrasion. Mr. F. P. CEMBRANO, jun., gave a demonstration of *Transparency-making without a Dark Room*. He said that it was his aim that evening to demonstrate that no dark room, nor even a developing lamp, or the use of non-actinic media, were at all necessary for the pursuit of that fascinating branch of photography, transparency-making. The reproach that amateurs were selfish because, no sooner they returned home from work, they shut themselves up in their dark rooms, could no longer be cast upon them. Long winter evenings could be sociably spent at home without giving up lantern-slide work, and, provided a little care was used when developing and the table was covered with a piece of oil-cloth, no damage need be feared for the furniture or carpets. Mr. Cembrano followed his remarks by developing several plates by the light and within three feet of an ordinary Argand gas burner, several of the gas jets in the room remaining alight. An ordinary dish was used, and the plates, while in the developer, were not screened from the light. The resulting transparencies showed absolutely clear glass in the parts that had been protected by a mask during the exposure. The exposure (contact) was one inch of magnesium at distances from three to ten inches. The first slide was made on a Cowan chloride plate, and was developed with pyro and carbonate

ammonia, and bromide and acetate of soda. The second one, also a Cowan's chloride plate, was developed with hydroquinone, caustic potash, and carbonate of ammonia, the resulting colour being a nice brown. A collodio-bromide plate gave also equally good results. The demonstration was brought to an end by exposing two of Marion's Bartolozzi opals, one of which was developed with amidol and the other with hydroquinone. The former gave a black image, while the colour obtained with the second developer was light sepia. Mr. ENNIS asked which would be the best way to obtain warm tones on slides. Mr. CEMBRANO replied that, with gelatine as well as with collodion, plates any colour, from black to red, could be obtained. He had not been able to get warm tones with eikonogen, but with pyro or hydroquinone a good rich colour could be got by giving a prolonged exposure and using a well-restrained developer containing carbonate of ammonia. Mr. ABDASKER added that he had obtained a warm tone with eikonogen by using carbonate of ammonia. The subject for discussion at the next meeting will be on *Preparing Work for Exhibitions*.

Croydon Camera Club.—October 31, Mr. Maclean in the chair.—Messrs. Diamond and J. B. Hartland were elected members. In consequence of gas supply failing, the showing of members' slides was postponed to Wednesday, November 2. Mr. C. E. Whitaker exhibited a large number of views of good quality (notably some toned by the Weir-Brown process), and Mr. Bray a strikingly original example of "picture-making," entitled *The Hay Nest*. On Friday, the 4th, the Robinson slides will be shown at Braithwaite Hall. Monday, 7th, Mr. Charles Hussey lectures on *Stereoscopic Photography* at the Club Rooms.

Aston Photographic Society.—At a meeting of photographers, held on Friday last at Burlington Hall, High-street, Aston, it was decided to establish a Photographic Society for Aston and district. Mr. Councillor SYDNEY FISHER presided, and spoke of the desirability of forming a means of social and mutual intercourse between those who practise the "dark art." There were also present Messrs. Tylar, Cracroft, Wollaston, Priddin, Casson, Cole, Wimwood, Dent, and other gentlemen. Among resolutions passed were the following:—"That a Photographic Society be formed." "That it admit amateurs and professionals." "That it meet fortnightly." "That it meet at Burlington Hall." "That we approach the Aston Natural History and Microscopical Society with a view to affiliating the Photographic Society with theirs, but taking alternate Thursdays for our separate meetings." The meeting was then adjourned until Thursday, the 10th inst., to decide upon future business then, and, after a vote of thanks had been passed to the Chairman, the company dispersed. Twenty members actually joined. Fee: 5*s.* per annum, or 2*s.* 6*d.* half-yearly, payable in advance. Communications to Fred. W. Pilditch, Acting Secretary *pro tem.*, 133, Wills-street, Aston.

Liverpool Amateur Photographic Association.—October 26, the President (Mr. W. Tomkinson) in the chair.—Messrs. A. Bradbury and E. V. Swinden were appointed to audit the annual accounts. Mr. R. J. Sayce exhibited two fine platinotype pictures of *The Strid* and *The Meeting of the Waters*, Bolton Woods, from negatives taken direct on 25×23 plates by Mr. Wm. Brown, of Leeds. Mr. C. B. Reader brought before the meeting an invention by himself and Mr. Potter, consisting of a new method of artificial lighting, specially adapted for enlarging and reducing. Taking equal quantities of magnesium powder and chlorate of potash, Mr. READER explained that, by means of a piece of perforated zinc, he distributed it equally over a sheet of pyroxyline paper, and upon this he pasted another sheet of the same paper. A piece of this preparation, about ten inches square, produced, when ignited, a flash sufficiently bright and lasting to make a lantern slide by reduction from half-plate. Mr. Reader showed a slide made in this way, which was equal in all respects to those made by daylight.

Stereoscopic Club.—October 28, Mr. James Whitelegg (President) in the chair.—Mr. W. LEACH read a paper on *The Projecting Polariscope*, with practical demonstrations in its use, showing that Nicol prisms of large size were no longer necessary, and that prisms having one inch or one and a quarter inches field, used in the lantern microscope, were sufficient to exhibit the maximum-size objects—viz., one and three-quarter inches—and also that, when even this size could not be obtained (for at the present day they were somewhat precious articles), a bundle of thin glass plates, using transmitted light in the lantern microscope, was a splendid substitute, and capable of producing results that could only be identified by experts in the science, and far surpassing the possibilities of the elbow or reflecting polariscopes, even when of the largest size. During the demonstration Huyghen's double-image apparatus was exhibited and explained, as was also the heating and compressing of various glasses, crystallisation, selenite, quartz, and mica objects, Norremberg combinations, &c. During the discussion which followed the lecture a member expressed himself deeply interested in the beautiful phenomena that had been shown upon the screen, but he confessed to not understanding "what it was all about." In the first place, he would like to know what was meant by polarised light? Mr. W. I. CHANWICK said the term "polarised" was not a happy one, and thought that, if the phenomena had to be rechristened a better term might be found. It was difficult to convey a clear understanding of the meaning of polarised light in a few words, especially to those who had not studied the nature of ordinary light. If a rope were stretched across a room and vibration be given to one end of it, say, in an up-and-down motion, the vibration would proceed to the other end as waves or undulations; if now vibrations were given to the rope sideways, say, from right to left, these would proceed as waves or undulations at right angles to the first series of waves; and, if a multitude of such ropes were made to vibrate in every possible plane transversely to the length of the ropes, they would represent the vibrations of a ray of common light, light being the vibration of an elastic medium which pervades all space, as sound is the vibration of air. But, when these ropes are caused to vibrate all in the same plane, they would represent polarised light. In other words, common light has all its vibrations in every possible plane transversely to the path of the ray, but in polarised light the vibrations are all reduced to one plane. A hearty vote of thanks was passed to Mr. Leach for his paper and demonstration. Mr. W. I. CHANWICK read a paper on *Dissolving Views* [see page 711], and gave a limelight exhibition of various modifications of what is generally understood as dissolving views. Some charming pictures were shown, and the apparatus much admired for its simplicity and efficiency.

Leith Amateur Photographic Association.—October 25.—The President (Mr. Dougall) introduced the lecturer for the evening, Dr. HUGH MARSHALL, who had taken as his subject *Lantern Work*. The Doctor, in his opening remarks, stated that the general consensus of opinion was in favour of wet plates, as producing in skilled hands the highest class of work of this kind, and with that he was in full agreement, but at present gelatino-bromide plates were in the ascendant, and in careful hands they *almost equalled* those of wet plates. Taking the popular gelatine plate as the key, he went fully into the chemical constituents and conditions of the lantern plates of that class as supplied to the amateur and professionals, and proved the possibility of having a perfect gelatine plate. Printing by contact for this purpose ("lantern slides") he explained and demonstrated, as well as copying from larger sizes by the camera. A simple but efficient apparatus of the kind, of his own construction, was shown, explained, and demonstrated. Another mode, he stated, of making either enlargements or reductions was by the optical lantern, a very simple form of which of his own make, recently devised, being shown, and by it he demoustrated his methods of making enlargements from quarter-plates or portions of larger plates. The making of slides from beginning to end was also skilfully shown, the Doctor showing himself to be a skilled mechanic as well as a high scientist in this department. In treating of the production of transparencies for other uses than the lantern, he was decidedly in favour of the use of matt varnish on the film side of the plate rather than the ordinary method of using ground glass, the latter being so variable in its character, the finest being very expensive, and the examples shown, were certainly good proof of the Doctor's skill in the use of his favourite medium. Thereafter he treated fully on the various developers for transparency purposes, explaining the qualities each had for giving tone, colour, delicacy of shade, and other qualities, demonstrating these without a hitch, using the ordinary gas for the light and his own apparatus for the other parts of the demonstration. At the close of this most successful meeting, and after lucid answers to many questions, the thanks of the body were tendered in most grateful fashion by the President for the delightful evening they had enjoyed, especially from its educational point of view. Before closing, the SECRETARY stated that he had been supplied with samples of the new developer, amidol, and related his experiences with it, and distributed them to those desirous of trying it. The next meeting is to be occupied with the annual exhibition of members' work for the past season, and in this connexion would it not be well for this and other Councils to consider the desirability of altering the annual meeting for the appointment of office-bearers to such a date as would allow the names of the newly appointed body to be printed in the current year's ALMANAC, instead of being a year behind date, as some of them are at present?

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE MEASURES OF DRY PLATES.

To the EDITOR.

SIR,—I do not know of any small matter that makes so much trouble to a man on a journey as the irregularities in the sizes of dry plates. I do not allude to the unpardonably careless cutting, by which the angles of the plates are not always right angles, or of an occasional neglect to cut in the right place, so much as to the want of a general understanding as to the measure. I have recently had some trouble with discrepancies between the ideas of the camera maker and the dry-plate manufacturer, due to the amiable mutual disposition to make way, each for the other, the former making a little allowance for the plate being not exact in its dimensions, and the latter calculating that the holder would be exact in its accommodation, and so cutting his plate a little short in measure, the consequence of which was that my plates went through the holder in some cases, and generally left one edge uncovered. With glass plates this is not so much matter, but when one uses celluloid films, as I am largely doing now, the edge that is not held in the frame of the holder gets out of the focus as well as out of the plane. Why should the societies not take up the matter and try to establish a general rule that the plates shall be in all cases cut to the *exact* nominal measure, and the camera makers make the slight allowance needed for the occasional, perhaps unavoidable, errors in cutting? For the carelessly cut plates there is no excuse, and the seller of them ought to be denounced and avoided; for, with the mechanical appliances now at hand, the cutting of plates to exact measure, barring variations in the fracture of the glass, is as easy as to cut carelessly and inexactly, but I have had celluloid films of an excellent and well-known make recently which were all cut the sixteenth of an inch short in both dimensions. The holders gave a sixteenth of an inch play, and the consequence is that there is the eighth of an inch to spare on both dimensions. The sight-measure of the holder is correct, but the play in the holder becomes too much, and the film sometimes misses its hold. If the plate makers will use the practicable appliances for cutting their plates with precision, and the camera-makers will leave play to the amount of one-sixteenth of an inch, it would be a great convenience for at least one experimenter who has not much time or patience to waste.—I am, yours, &c.,

NOV. 1, 1892. A WORRIED AMATEUR.

SILVER STAINS ON UNVARNISHED GELATINE NEGATIVES.

To the EDITOR.

SIR,—Gelatine negatives may be printed from without being varnished. This has been so written in many works on Photography. Quite right, they can; but in nine cases out of ten it means ruin to the negative later on. There must be many thousands of negatives apparently spoilt and useless for printing in the hands of professionals and amateurs, suffering from what I may best describe as silver measles, and put aside as worthless.

Several formulæ have been published to remove the same. Some will do so, but they have one little drawback, they generally remove the subject also. I recently had a charming series of negatives by a deceased amateur; many of them were very badly stained. Not liking to destroy them, I made a very exhaustive series of experiments, and at last was awarded for my pains by finding that by the aid of a very old and valuable chemical I can in a few minutes remove the silver stains without injury to the negative in any way. No previous soaking or after-washing is necessary; the solution is perfectly harmless to the negative, and does not contain any cyanide, acid, hypo, or anything that I have ever seen mentioned.

Now, as the proof of the pudding they say is in the eating, I make the following offer. I invite any and every professional or amateur photographer to send me during this next fortnight a negative such as mentioned by parcel post, and enclosing a properly directed card, with the necessary stamps for the return postage (without which I must respectfully decline to forward the same), and I will without charge send the negative back, and I think there will be no sign of silver measles. After that, if satisfactory business, I will call and show you some very bad samples with stains partly removed, and I will remove the other portion in a few minutes; but you will, I am sure, excuse me not showing "how it's done." I look upon it as a very valuable discovery, and in this instance I think I must keep it a secret, and try, while helping others, to help myself.—I am, yours &c., HORATIO NELSON KING.

4, *Avenue-road, Goldhawk-road, Nov.* 1, 1892.

[We may say that our friend, whom photographers generally will recognise as one of the few remaining clever veterans to whom the art owes so much, practically demonstrated the method at the Editorial offices, and we can testify to its efficacy and success. It should prove an idea of great value in actual practice.—ED.]

THE IMPERIAL PORTRAIT ASSOCIATION.

To the EDITOR.

SIR,—I was pleased to see the letter from your correspondent, William C. Ledger, referring to the Imperial Portrait Association. Some few months since they issued circulars to the public offering to take enlargements of cabinets free of cost, as they thought by advertising in this way they would ultimately get a good business, &c. I sent my picture; they have the enlargement, and want me to pay for it. I won't from principle. They won't return my picture. What steps would you take, Mr. Editor, to get from them my picture sent to them at their solicitation?—I am, yours, &c., ED. BIRKHEAD.

Lewes-street, Manchester, Oct. 31, 1892.

THE ARK.

To the EDITOR.

SIR,—I have been greatly interested in the published account of the finding of the Ark of the Bible by Archdeacon J. J. Norris, and I should be much obliged if you would let me know if the reverend explorer took a snap-shot of the marvellous object; and in that event, if and where copies can be purchased?—I am, yours, &c., JOHN GREEN.

[This subject is referred to in our leaderettes.—ED.]

MYSTERIOUS MARKINGS ON NEGATIVES.

To the EDITOR.

SIR,—May I be permitted, as an old amateur plate-maker, to relate my experience of markings such as those spoken of in your issue of the 28th?

For several years after the introduction of the gelatine process, I followed the general practice of drying plates in a box, through which a current of air was made to circulate by means of a gas flame. Plates of excellent quality, and free from these markings, may be obtained by this method of drying, if the current be maintained with unvarying steadiness, and the plates are not packed too closely. But if no mechanical arrangement is provided for regulating the supply of gas, sharply-defined lines, corresponding with each alteration in the pressure may be expected. It does not always follow, except in extreme cases, that these markings will be visible in the finished negative; but evidence of their presence may be obtained by holding a negative, when just surface dry, at the angle of reflection between the eye and a source of light, when, if the plate suffers from this fault, a line, or lines, may be perceived similar to, but not so deep, as those which divide the wet from the dry portions of partially dried negatives. Your correspondent may rely on this as a certain indication of faulty drying.

My plates being all required, either for stereoscopic negatives or transparencies, the necessity for spotless results caused me to abandon this method in favour of the slower, but more cleanly, plan of drying in a closed box, by the aid of calcium chloride. I soon discovered, however, that if any marked difference in the temperature of the room was allowed between the night when the plates were coated and the succeeding day, that markings of a somewhat different character appeared, development proceeding normally in the centre, but leaving the margin, perhaps for half an inch all round, pale and lagging. Now, my experience of these markings is that, if development is pushed on rapidly, there will be a distinctive band round the plate of less density than the centre portion; but if reasonable time be allowed, and the ammonia added progressively, and more especially if a somewhat stronger solution be applied round the edges with a brush, no marking will be visible. Is it likely that we have here an explanation of the difference experienced between manufacturer and user in the case cited?

Again, if plates are dried on heavy racks, which obstruct the free access of air to given portions, faint lines, or comet-like streaks, following the direction of the leaning-post, may be expected. For this reason I have found it necessary to use racks of the slenderest character, and to cut away the contact portions to a knife-edge. I think there are very few users of commercial plates who have not met with this defect at one time or another.

Insufficiently washed emulsion also gives rise to bands of a peculiar description, the margin and centre developing normally, but leaving a midway band of less density, some half inch wide. In extreme cases, the band is visible before development, and may be tacky or crystalline, in accordance with the soluble bromide which has been used. This defect is, however, out of the question as regards commercial plates.

I think it will be allowed, on reflection, that these markings—except the last named—may all be traced to one cause, namely, the varying rapidity at which given portions of the film are dried. In the first example, only a slow circulation would be induced by the midnight pressure of gas, therefore the centre of the plate, having the advantage of greater pressure, would be dried in less time, area for area. In the second example we have practically the same conditions; the plates being boxed late at night merely having the advantage of a sluggish current, due to the difference in density between moist air from the plates and dry air from the calcium chloride; whilst, during the succeeding day a better circulation would result from the gradual elevation in temperature. The difference between the two cases being that, in the latter, the two portions of the film merge quietly one into the other; and in the former—which are difficult to manage in development—there are one or more sharp dividing lines. The third case, relating to faint streaks or comets, manifestly arises from the same cause.

This result of quick or slow drying would seem to relate only to the gelatine, and not to the silver bromide, those parts dried slowly being least permeable to the developing solution. In support of this view, it is only necessary to examine a surface-dry negative in the manner suggested above, when it will be seen that the margin of such defective plates, or band of least density, is less elevated than the remainder.—I am, yours, &c., J. MELLALIEU.

6, *Long-street, Middleton, near Manchester.*

REMINISCENCES OF AN OLD FOGEY.

To the EDITOR.

SIR,—I saw to-day in one of your recent numbers an article on the "Preservation of Sensitised Paper." I was an enthusiastic amateur in "the fifties," and used to preserve my sensitised paper in a tin canister lined with paper, having a false bottom under which was a tray of fused chloride of calcium. A broad indiarubber ring round the junction of the canister and lid rendered it air-tight, and in the dry atmosphere sensitised paper would keep indefinitely, and now, while my pen is in my hand, pardon an old fogey if he twaddles a bit about the troubles of thirty-five years ago.

At that time I used to belong to the North London Photographic Association, the President being your then editor, Mr. Shadbolt. I think we used to exercise more care in the selection of our views then, when our plates cost us so much trouble to prepare. *Of course I except the masters of photographic art at the present day.* A short time ago I was in the Channel Islands, and on one of the cars which make daily excursions was an amateur photographer. When the car stopped and we all rambled about on a beautiful bit of coast scenery, I was amused at the "a. p." and his eagerness to pitch his camera; he selected a place (or rather put his camera down without selection) when he had the chimneys of a cottage in the foreground, and little else but sea beyond. Only one hundred yards along the path he might have got the cottage with a background of trees leading up to the path where he had stood; on the right a grand semicircle of rocks, and trees beyond stretching round across the picture in front and beyond the headland, the sea on the left. I introduced myself as an old "a. p.," and gently suggested a little more thought, but got

rather a curt answer. I suppose he had got his plates where, they say, "all you have to do is to press a button, we do all the rest!" In the fifties we had something more to do than press a button! A week's outing meant many hours' hard work, much anxious and careful cleaning and coating of plates, washing, preparation and filtration of "preservatives"—I used sometimes albumen, sometimes linseed emulsion, sometimes gelatine, sometimes gum arabic— much patient submission to semi-suffocation and irritation of the eyes from the ether fumes, and then the trouble of drying the plates without a check, which caused a line across the plate, and the care to avoid dust which caused pinholes. Now, after all this trouble, we did not waste our plates. My plan was to walk over the ground without my camera, notice the best point of view for every bit which attracted me, and the points of the compass, so that, if I found the best point to stand the camera was facing south, I knew it was no use being there at twelve o'clock. I then used to go again with my camera, timing my walk so as to arrive at the various selected points as near as possible at the best time.

And then the hard work! I worked 10 × 8, and cameras were not made so light as now, nor the stands, as we often had to give fifteen minutes', *not seconds'* (think of that, ye button-pressers!), exposure, and after each exposure had to go down on my knees with my head and shoulders in a black bag, with a square of yellow tammy and change the plate—jolly on a hot day!

Then the excitement of developing with acid pyro, and the delight of seeing a successful negative. That was the best part of the whole business. But, alas! when plate after plate turned out bad either from over or under-exposure, or from some accidental defect in preparation, then came swear words, I am afraid.

About 1860 I very nearly stumbled upon the emulsion system which has done so much for photography. About that time appeared in your JOURNAL a method of forming a film by dissolving cotton in a solution of copper in ammonia. As collodion was expensive and I was not rich, I took some pains with this idea. Of course, putting into it a plate coated with something containing copper and ammonia soon played the very dickens with the nitrate bath, and so I tried dissolving bromide and iodide in water and precipitating with nitrate of silver and adding the precipitate to the cupric solution of cotton. I *now* suppose that my dark room as then constructed was not sufficiently non-actinic, and that I had no idea of the sensitiveness of the precipitate. Anyway I failed. Although, owing to an accident which left me lame for life, I had to give up photography in 1861, I still like to read the journals and see what is going on, and if I can get an amateur to accompany me for a day in my trap I can take him to some choice bits and enjoy his company.—I am, yours, &c.,

October 28, 1892. OLD FOGEY.

POLARISED LIGHT.

To the EDITOR.

SIR,—I am not aware that the part played by polarised light in landscape photography has been fully pointed out. It is well known that the light from all parts of the blue sky is partly polarised, and that the amount polarised reaches a maximum in directions at right angles to the sun's rays. By using an analyser (a Nicol's prism, for instance) in conjunction with the lens of the camera, the polarised light can be entirely cut off, while the ordinary light, such as that from clouds, &c., is only partly extinguished. This use of an analyser appears to furnish a means of obtaining contrast between blue sky and clouds, &c., on the sensitised plate, and may also be found of service in obtaining natural clouds on landscape negatives. The light reflected from the surface of almost every substance is completely or partly polarised according to the angle of reflection, and this is the case with the white reflected light or glare from the surface of grass and landscape objects. By the use of an analyser with the lens this surface glare can, therefore, be partly cut out, leaving the light reflected from below the surface, which gives the object its colour, to reach the sensitised plate more or less unadulterated.—I am, yours, &c., W. GROVES.

Melford-road, S.E., November 1, 1892.

[The "part which polarised light plays in landscape photography" has been fully set forth and treated of in former volumes of this JOURNAL.—ED.]

KEEPING QUALITIES OF DRY PLATES.

To the EDITOR.

SIR,—Having read with interest the correspondence in your paper concerning the keeping qualities of gelatine dry plates, perhaps I may be allowed to give a recent experience, which proves that plates do not necessarily deteriorate through prolonged keeping. Coming across several boxes of plates which had been stored away for five or six years, I made a few experiments with them. Some of the dozen negatives produced were developed thin, and others dense, but in no case were any markings visible either at the edges or elsewhere. The plates developed clearly and rapidly, pyro-ammonia being the agent employed, and in every respect the results were similar to those obtained on new plates. The plates were packed in fours, face to face, with folded card at the edges, preventing actual contact of the films, each four plates being wrapped in orange paper, and the whole box wrapped and sealed in thick brown paper.

Stored in the same cupboard were some boxes of the same and other brands which had been opened and carelessly repacked, and these showed before exposure a discoloured band of nearly an inch in width all round the edge.

The plates were, of course, in a dry place, and I think their condition, after the length of time mentioned, goes to prove that, kept from the atmosphere by careful packing, an average brand of plate will remain for a considerable length of time in good condition.—I am, yours, &c.,

DRY PLATE.

To the EDITOR.

SIR,—In reply to the query, "Do Plates Deteriorate by Keeping?" I have exposed and developed a 12 × 10 plate which has been in stock over three years. Although something like twice the normal quantity of ammonia was required to bring out detail (owing to plate being under-exposed), the negative developed as free from fog and stain as a freshly prepared plate. I would, however, mention that I have had a whole batch of plates of the same make completely ruined in less than a year, stored under precisely the same conditions—in fact, side by side with the above. This I put down to the tissue paper used in packing, as the plates developed to full density where paper had not touched them, the portions in contact being insensitive.—I am, yours, &c.,

Whitby, November 1. J. ASTON BRIGGS.

THE EYE AS A CAMERA.

To the EDITOR.

SIR,—The reproduction of one's original ideas must, of course, be taken as complimentary; some acknowledgment is, however, generally considered fair and courteous.

I read, in your last impression, that a lecture on "The eye as a Camera" was given on the 4th ult. at Blackheath. At pages 18 to 25 of the second edition of my book,* *Photographic Manipulations*, will be found, illustrated with woodcuts, the first comparison made on this subject. Now my position is this, I am preparing for press the third edition of my work; if I remain silent now, when my book appears I, and not the lecturer, shall by my future readers be considered the plagiarist. —I am, yours, &c., LAKE PRICE.

Lewisham, November 1.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the EDITOR.

SIR,—On behalf of the Benevolent Association I beg to thank you for your suggestion on page 691 of your current issue. If the different Societies would act upon it, and devote the proceeds of one evening to the Benevolent, there is no doubt that a very great and good work could be done. It is curious that the same idea often strikes two or three people at about the same time, for only two or three days before your suggestion appeared I received a letter from Mr. Frederick Hollyer, offering to give to the Benevolent the proceeds of the last day of his Exhibition, now open at the Dudley Gallery, Egyptian Hall, Piccadilly. Mr. Hollyer writes: "I offer this, firstly, because I know that the money will be useful to the Benevolent, and, secondly, because I hope that the example may be followed by many other promoters of photographic exhibitions, and by the committees of the photographic societies throughout the kingdom." We have already appealed to the secretaries of the photographic societies in London to assist us by the sale of tickets for the Lantern Exhibition in aid of the Benevolent, which is given by the Photographic Society of Great Britain at their exhibition rooms to-night (Friday, November 4). We trust that every one who is interested will do what he can to make this a success, and also to give the Benevolent a good benefit on Mr. Hollyer's Benevolent day, which will be Saturday, November 12.—I am, yours, &c., H. SNOWDEN WARD,

Memorial Hall, E.C. *Hon. Secretary P.B.A.*

PHOTOGRAPHIC CLUB.—Wednesday, November 9, Open Night. Demonstration of *Cresco Fylma*. 16, Annual Dinner.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—November 10, paper on *Out-door Work*, by Mr. Ernest Milner. 17, Monthly Lantern Night. 24, Members' Open Night.

CROYDON CAMERA CLUB.—Fixtures: November 4, *Picture-making by Photography*, at Braithwaite Hall. 7, *Stereoscopic Photography*, by Mr. C. Hussey, at Club Rooms, 56, George-street. 21, Lantern Night; Members' Slides.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—November 8, Ordinary Meeting at the Gallery, 5A, Pall Mall East; Address by the President; Presentation of the Medals; paper by Mr. Howard Farmer on *Some Remarkable Properties of Silver and Gelatine*.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—November 11, opening of the Association's new rooms at the Art Gallery, Newcastle; *Conversazione* at a quarter to eight, and Exhibition of Photographs, Stereoscopic Slides, and Lantern Demonstrations.

* John Churchill & Sons, London.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

H. C. Pettitt, Kewick.—*Photograph of embroidered pall used at Lord Tennyson's funeral.*

William Currey, Morecambe.—*Photograph of Dorothy Drew and the Right Hon. W. E. Gladstone, M.P.*

ANCIENT.—Received. Thanks.

ALBERT LEVY.—Thanks; we reciprocate your friendly sentiments.

DERENHAM & Co. (Weston-super-Mare).—Sichel & Co., 52, Bunhill-row, E.C., is the address.

T. BRAIN.—Use the sulphocyanide toning bath as recommended by the Company, and your trouble will, no doubt, cease.

CYMRO BACH.—We are not acquainted with any English work on retouching containing illustrations showing the different details of the art.

S. PORTER.—Any mixture of water colours that will match the tone of the print, strengthening the shadows with the addition of ordinary gum.

C. R. TRUEMAN, Albany Studio, Shrewsbury, wishes to communicate with Mr. A. Flint, who wrote us in regard to a flashlight arrangement. We have not kept the latter gentleman's address.

T. O. MORGAN.—One or more articles on the subject will appear in the forthcoming ALMANAC. They will supply far more information than it is possible to give in the limited space of the column.

L. M. says: "Can any of your readers give me the date of the number of the JOURNAL in which there appeared a table showing the comparative cost of lighting by gas, electricity, and oil?"—See page 140 of the JOURNAL for February 26.

SEPTIMUS.—The query about the regulations as to exhibits at the Chicago Exhibition should be referred to the Executive. A letter addressed to Sir H. T. Wood, Society of Arts, John-street, Adelphi, W.C., will secure the desired information.

A. W. R. complains that some pyro developer he mixed a week ago has gone to a deep sherry colour. On trying it, he says it works all right, but asks if there is any danger of the negatives developed with it turning yellow in time?—No; or, if they do, it will not be due to the developer.

T. T.—If the mounts are not of the kind ordered and the name is wrongly spelt, you are not bound to accept them. With regard to their being sold to any other person at a future time, we can say nothing, except that we should expect that no respectable house would do such a thing.

A. S. says: "In last week's JOURNAL appears an extract from *Anthony's Bulletin* in reference to an electric retouching pencil. Can you furnish me with any details of same? If not, where can I get information concerning same?"—Apply to Messrs. E. & H. T. Anthony & Co., of New York.

BACKGROUND says: "Can you inform me where I can obtain information about painting backgrounds? I wish a few hints on mixing distemper, and also advice as to what material to work on, and where to obtain it."—Such information is to be obtainable in the volumes of the JOURNAL for 1888, 1889, 1890.

GUARD.—The Welsbach light is not so good for enlarging purposes as the limelight. For enlarging on bromide paper a blow-through jet will answer every purpose. The exposure may be a little longer than with a mixed jet, but you will do well to put up with that at the expense of safety, as you are a novice with the light.

W.—Your query is one more particularly for a solicitor, as so much would depend upon the wording of the agreement. It seems to us that the restriction of a radius of twenty miles is *ultra vires*, but it is quite possible the agreement would prevent you from setting up in business in the same town, as it is but a small one.

GEORGE BANKART.—We are afraid we cannot assist you. The composition of the Platinotype Company's intensifier being a secret, it would be mere guesswork on our part to attempt to indicate a solvent of the image. Have you tried the effect of bleaching it with ferric oxalate, and redeveloping after a thorough washing? This might change the colour.

J. MOSES.—There would be little novelty in the camera if it depended only upon the material of which it was constructed. Cameras of small sizes have long ago been made of ebonite, and similar material. There may, however, be such novelty in its design as to entitle it to a patent. But the application of the material alone to cameras would not.

A. L. asks which is the hardest and, at the same time, purest gelatine in the market?—This is a difficult question to answer. On the whole, we should be inclined to give the preference to Nelson's X opaque. Some of the foreign gelatines are equally as hard, and perhaps more sightly in appearance, but they have the disadvantage of being more or less acid.

S. R. W. asks how to boil a solution that contains a considerable proportion of sulphuric acid, as an ordinary tin or iron vessel will not answer, and the enamel of the enamelled ware is seldom perfect. The best thing for the purpose is a Florence flask. They are supplied of all sizes by every dealer of chemical apparatus. For working on a large scale platinum vases are used, but we presume our correspondent wants something for an experiment only.

J. A. KAY.—1. Bromide paper usually curls "inwards" on the sensitised side, and the application of the tongue to a corner indicates to you the gelatine; thus there are two means whereby you may know which is the right side. 2. There are several photographic journals published in America. Messrs Percy Lund & Co., Memorial-buildings, E.C., will give you all particulars.

INQUIRER (Dublin) writes: "Is it practicable to enlarge direct on carbon tissue by the limelight? I should like to use the process for enlarging, but to first make a transparency and then an enlarged negative makes the thing impracticable to me."—For actual work the limelight will not do. It is not strong enough. The exposure would be so long, and the cost for gas so great, that the thing might be classed as impracticable.

B. W. J.—By a faded Daguerreotype we presume one that has become tarnished is meant. If so, the picture can be restored to its original state by treatment with a solution of cyanide of potassium. The details for doing it have often been published in these columns; but, if the picture is a valuable one, our advice is, Place it in the hand of some one who is familiar with the Daguerreotype process, or else get some other one of no value to experiment upon before treating *the* one.

R. THOMPSON.—If the negative is so extremely feeble, and resists all methods of intensification that you have tried—and you have named the best—the only way to make it serviceable is to reproduce it. First print a transparency on a plate giving good density, modifying the development so as to increase the contrasts. Then from that make a new negative, again proceeding for increased contrasts. By this means from the most feeble negatives a good printing one may be obtained.

C. W. says: "Can you please tell me if it is possible to copy any photographs up to half-plate, the same size, in my half-plate camera, which has a 7×5 rapid rectilinear lens optimus, and when the camera is racked out full it is sixteen inches from diaphragm slot to focussing glass? Can you please give me any rule for ascertaining the distances between photograph and lens, and lens and dry plate? The lens is advertised as eight and seven-eighths focus."—Consult the ALMANAC for 1892, in which a table for computing enlargements is given at page 858.

C. BLAKE sends two print enlargements on bromide paper. In one he complains of the inky black and chalky lights, and in the other of the grey even tone all over. He says he has made several enlargements from the same negatives, and they always seem the same. He asks if the negatives are at fault?—So far as we can judge they are all right, but the one is dense and the other is the reverse. The one print is as much over-exposed as the other is under-exposed. A shorter exposure in the one case, and a longer one in the other, will produce equally as good results.

S. DURNFORD.—If you have no experience in plate-making, we should certainly advise you to have your plates from England as you require them. Plate-making, under the most favourable conditions, particularly when the utmost sensitiveness is essential (as it must be in your case) requires considerable experience. In a climate like that of India during the hot season that would be still more necessary. If you received the plates in small tin-lined cases, and only opened them as the plates were required, there would be little risk of the hot, damp atmosphere injuring them.

S. J. writes: "Would you kindly inform me what solution is used to prevent the collodion film of a wet plate from washing off during development and washing? I know about flooding the glass with an egg albumen, but there is a kind of rubber solution used, painted round the edge of the plate with a wall brush, forming a safe edge."—With perfectly clean glass, and a good collodion, nothing is required. In order to save the trouble of cleaning the glass, a coating of dilute albumen is sometimes used. An edging of dilute solution of indiarubber in pure benzol may be applied to the edges of the plate if the collodion is of a very contractile kind, but the glass must be perfectly clean.

FORTHCOMING EXHIBITIONS.

JOURNAL OF PHOTOGRAPHY.

No. 1697. Vol. XXXIX.—NOVEMBER 11, 1892.

METHODS OF ARTIFICIAL ILLUMINATION FOR ENLARGING OR REDUCING.

Now that we are well into the lantern season and the period of home employment, in contradistinction to outdoor work with the camera, the question of artificial light for purposes of enlargement or the production of lantern slides will, no doubt, assume an increased importance with many of our readers. For contact printing, whether on glass or paper, the matter of lighting is one of comparatively minor moment, since almost any form of artificial illuminant—even down to a wax vesta—will answer every purpose with our modern films.

But the case is altered when the camera has to be used, as must necessarily be the case when a reproduction on a different scale from the original negative is required, for the difficulty then arises with artificial light of securing an equal illumination of every portion of the negative. With daylight this difficulty is not experienced, since the parallel rays—or practically so—coming from a tolerably clear sky give a uniformity of illumination that is quite perfect. Not so with the divergent rays proceeding from the flame of ordinary artificial illuminants, which, while strongly lighting the centre portion of the negative, fall off so rapidly in power towards the edges as to produce the effect of a vignette.

To remedy this defect the correct plan is to employ a condenser—a system of lenses which, gathering up as many as possible of the divergent rays transmits them in a slightly convergent cone of uniform illumination on the negative to be reproduced. Now it must be plain that, in order to perform this duty in a proper manner, the condenser should be slightly larger in diameter than the diagonal of the plate to be illuminated, and that therefore, on the score of expense, the condenser can only be used in conjunction with small negatives.

As a consequence, from the earliest days attempts have been made to meet the difficulty of uniform illumination in other and simpler ways, chiefly by the use of a number of separate lights either stationary or in motion, and aided by reflection and screens of various kinds, in order to increase the equality of the diffusion obtained. Many such plans have been described in these pages from time to time, and only in our last issue a novel method is mentioned as having been brought before the Liverpool Society by two of its members. The plan is sufficiently ingenious in conception to be worth noticing.

It is based upon the adoption of the magnesium flash system, but the novelty consists in the method of securing uniformity of illumination over a considerable area, the limits of which are, theoretically, unbounded, though practically certain mechanical considerations must receive attention. A mixture of magnesium powder with finely divided chlorate of potash is spread evenly over a sheet of papyroxyline or gun-cotton paper, and a second sheet is then superimposed and made to a space so as to enclose the flash powder. As is well known, magnesium when burnt in the presence of oxygen, or any oxygen-giving substance like chlorate of potash, produces an extremely actinic light, and in the combination referred to the gun cotton supplies the means not only of securing perfect combustion, but also the necessary uniformity of diffusion.

In use, it is only necessary to fix, or suspend, a sheet of the flash paper the size of, or preferably a little larger, than the negative, at a short distance from the latter, and upon igniting it a flash or flame of great intensity and evenness will occur over the whole area of the plate. The uniformity of action produced by such an arrangement would, it is not difficult to imagine, be sufficient to satisfy all requirements, even when used in close proximity to the negative; but, when a moderate distance intervenes between the plate and the source of light, the effect should be almost perfect, though, of course, a larger area of flash paper would have to be used. And here comes one of the possible objections to the method, namely, the inconvenience of igniting or exploding large sheets of papyroxyline, rendered additionally dangerous by the combination with chlorate of potash. Another difficulty that can easily be foreseen is the danger in handling the compound paper, especially in cutting it to size, as a very slight amount of friction would, we imagine, suffice to ignite it, with possibly not very pleasant effect.

The generally safer plan will be to adopt one of the many systems of multiple lights that have been described in our columns. The flash system with magnesium powder lends itself readily to the production of uniformity of illumination owing to the comparatively large surface of flame produced; but it is liable to the objection already mentioned, the danger and inconvenience of igniting large quantities of the powder at once and of making successive exposures with the accompanying clouds of smoke. The ignition of a single strand of magnesium wire or ribbon, except at a considerable distance from the negative, can certainly not be recommended on the score of evenness of lighting, and with the increase of distance comes a loss of illuminating power that seriously militates against its practical efficiency, so that the multiple system of lights is the one to be preferred.

The first arrangement of this kind that comes to our recollection is one that was shown at a meeting of the South London Photographic Society in 1879 by Mr. Brittlebank, and, though specially intended for portraiture, it seems to commend itself equally for the purposes we have under consideration.

It consisted of a screen or sconce of bright tin provided

with a number of tubes at regular intervals over its surface, through which strands of magnesium wire could be propelled by means of a simple mechanical arrangement. Beneath these tubes were, if we remember rightly, rows of small gas jets for the purpose of igniting the magnesium. When an exposure was to be made the gas jets were lighted, and could be kept burning during the whole evening at a slight expense. The separate strands of magnesium passed over or between rollers, all of which were actuated by the motion of a single winch handle, upon turning which the several strands of ribbon were pushed into their respective gas jets and simultaneously ignited.

For the purpose of securing complete equality of illumination over the surface of a negative of ordinary dimensions, say half-plate, it would probably be desirable to replace the bright metal screen or reflector with one having a dead surface, and of course it would not need to be of such large dimensions as for portraiture, some half-dozen strands of ribbon placed three or four inches apart being sufficient. It would in any case be desirable to allow the light to fall upon a sheet of ground glass placed a few inches from the negative, which, without intercepting an inconvenient amount of light, would conduce to greater uniformity in its diffusion.

Another method consists in the adoption of a reflector of roughly parabolic form, which may be used with a single light produced from ribbon or wire, or preferably by means of magnesium powder falling into a gas or spirit flame, placed on the focus of the reflector. The production of a reflector having truly parabolic curves is not an easy matter, but sufficient accuracy for our present purpose may easily be attained. A simple method of plotting out the necessary curve with extreme accuracy was exhibited at one of the "Brittlebank" meetings in 1879, and described in a leading article in our columns, but the mechanical difficulties surrounding the actual construction of such a reflector are considerable. A very effective, and, for all practical purposes accurate, instrument, may be constructed as follows :—

The object is to collect the rays proceeding from a point of light in a given position—known as the focus of the reflector—and to throw them out in a parallel or very slightly converging beam, the parallelism or otherwise depending upon the accurate position of the light. In the case of a large flame, and especially of a flash of magnesium powder, this becomes of less importance. Having plotted out the curve of the required reflector by the method alluded to, proceed to cut a piece of inch pine to the shape and dimensions required, and use this as a mould or pattern on which to bend a number of stout wires. Next prepare a circular piece of wood the size of the opening or mouth of the reflector, and bore at equal distances round its edge a number of holes, into which the curved wires are inserted, with their other ends meeting at a common centre, so as to form a sort of cage. In fact, if the mould or shape be placed in the hands of a birdcage-maker, with instructions to make a cage to that pattern, it will be the easiest way of securing a basis for the reflector. Of course, the more numerous and close the wires the better will be the ultimate effect.

Having obtained the frame or foundation, proceed to apply it in the following manner :—Cut a number of strips of paper wide enough to extend over two or three of the spaces between the wires, and it will make a better job of it if these strips are roughly shaped to correspond with the spaces. Having thoroughly moistened these, proceed to lay them as smoothly as possible over the wire foundation, joining the edge only with paste. When the frame has been entirely covered, similar strips are pasted over the first in repeated layers until a sufficiently strong shell has been formed, in the case of these last strips the whole surface, and not the edges only, being covered with the adhesive. The first layer of paper may be white, but brown paper afterwards will give greater solidity.

When, say, five or six layers have been built up, the whole arrangement must be put away in a moderately warm place to become thoroughly dry, and when this occurs the stiff shell is carefully removed from the wire foundation. The necessary apertures are then cut for the introduction of the illuminant and the escape of smoke, and the whole thing finished off in the best manner that suggests itself.

A less perfect reflector, but still an efficient one, may be constructed by nailing together four triangular pieces of wood so as to form a square pyramid, the shape of the sides and their consequent slope being so calculated as to throw out the rays proceeding from any agreed point in a nearly parallel direction. Such a reflector is within the capacity of any one who can use a saw ever so little, and in practice answers very nearly as well as the more perfect form.

The arrangements for inserting the light, be it gas or spirit, must be such that the magnesium is ignited at the focus of the reflector as calculated. If the whole can be made adjustable after the manner of the jets of an ordinary lantern so much the better, for then the position can be altered until the greatest evenness of illumination is obtained.

EXPEDITING WORK FOR CHRISTMAS.

The cry of the afflicted photographer is already being heard—"Christmas is close on us, and we can't get good prints in bad weather, neither can we hurry or expedite it; the light cannot be compelled," and so on. To a great extent his plaint is true; but, at the same time, he has in hand, if he cares to make use of them, many more expedients than was formerly the case. "The good old albumen print" is a sheet anchor; but even with it he need not lose the time he often, to our knowledge, does. Keeping, for the moment, to that style of printing, it is permissible to remind him that the loss of prints—good prints, that is—brought about by yellowing of the paper when bad light and exceptionally dense negatives cause the print after toning to be lacking in brilliancy and colour, need never occur if he use carbonate of soda impregnated pads in his printing frames. This plan is no secret, we have often referred to it; but how many utilise its benefits. It has positively no disadvantages beyond the possibility of injuring the surface of the varnish if a negative be left in contact with the backing. But to name this is to suggest a remedy. It may further be remarked that not only do these pads prevent the yellowing, but they permit the toning to proceed, with say a three days' old print, just as with fresh paper.

Then, again, we need not emphasise the merits of one or other of the brands of ready-sensitised paper now so freely offered. It goes without saying that following their use no yellowness or difficulty of toning, through long keeping in the printing frame, is experienced; but beyond this it is unquestionable that most of such brands in the market print distinctly more quickly than the usual home-prepared papers. We are aware that some photographers object to their use, though their number is rapidly diminishing, owing to the difficulty they experience in

getting their accustomed "tones." This, however, is mere matter of practice. Naturally the treatment required is different from that given to ordinary prints, and if the two be toned together uneven results often occur. A few experiments with variations of treatment will soon place the two on a level at the very least; and if a separate toning bath be kept for ready sensitised paper there need be no fear of its putting the toning bath out of order as some imagine it does.

But now, for winter work, there can be no question that albumenised paper is gradually being edged out by the gelatine papers that of late have been brought forward in profusion of brands. They are cheap—a very decided advantage—and, more important than all, their quick printing power is unquestionable, some holding them to be fifty per cent. quicker; but we have been credibly informed by those who have put them to the actual test that such a proportion decidedly understates the case, and that half the time required for albumenised paper more fairly represents what ready sensitised can do in this direction. To some workers, anxious for a reputation for permanency in their prints, the "combined toning and fixing bath," recommended for such papers, offers insuperable obstacles, owing to their belief that all probabilities are in favour of the resulting prints succumbing quickly to the hand of time. It is impossible to say with certainty, for there are prints in existence toned by that method, before the advent of alkaline gold toning, which appear as bright and fresh as the day they were printed, though it is well known that such examples of permanency are in a deplorable minority. But a few experiments will prove to any one that prints of the highest excellence may be toned without recourse to this old system (for, however new formulæ may modify old ones, the underlying principle is the same). Gelatino chloride paper can be toned, and toned well, to a variety of colours by one or other modification of the old alkaline toning baths. Carbonate, tungstate, biborate, and other soda salts, are now utilised with greater freedom than hitherto, and are capable of producing great variety of effects. Even the standard "acetate bath," used with judgment—though experts aver that it is not the best—is capable of toning these papers to very beautiful tones.

We have, further, papers of the aristotype brand or its many imitators. These are very quick printers, and possess many advantages that we cannot here pause to enumerate. It is enough to say that, by their aid, beautiful prints may be obtained from otherwise worthless negatives.

Lastly, we come to developed prints. It cannot be denied that many of the prints on bromide paper, as sent out from average studios, are wanting in transparency in the shadows; but here, again, practice is needed. Let any one turn to the pages of our ALMANACS of a few years back, and note what bromide prints are capable of. Even where beauty of results is the first consideration, we do not hesitate to say that some of the examples we refer to may, for richness and delicacy of colour, and good quality in the shadows, challenge comparison with any print ever produced by any process. "What man has done man may do" is a good photographic motto. And, looking on the rapid-printing side of the question, we can only say that with bromide prints it is a mere question of labour. A day will suffice to get from a large number of negatives a far greater amount of work than is ever likely to be needed in the busiest of studios. In conclusion, we can only say that a few judicious experiments, carried out with judgment and patience, will enable any photographer to settle, in the most satisfactory way, the question of how to expedite work for Christmas.

Photographs of Jewellery.—In most sensational law suits photography figures conspicuously in one form or another, but in the recent "Brooch Case" this was not so, though reference was made to drawings of the trinket in dispute. Had photographs of the two brooches been in existence, the trial would doubtless have been shortened, or, possibly, might not have been necessary. Many ladies are vain of their jewellery, and proud of showing it to their friends. Why should it not be tastefully grouped and photographed, and prints given to their friends? If that were done, in case of loss the photographs would frequently aid in its recovery. Photographs of some "family jewels" would be well appreciated by many in the upper circles. Here is a hint to enterprising photographers.

The Benevolent Association "Benefit" at the Photographic Society of Great Britain.—The "Benevolent" night at the Photographic Society of Great Britain Exhibition, on Friday last, was adversely affected by the heavy rain, and, as a result, the attendance was eighty-five less than last year. The number who paid at the turnstiles, however, was only two below last year's record, and it is not yet known how many tickets were sold and not used, so that the Committee of the Benevolent cannot tell how the monetary result will work out. Mr. J. Spiller, the Treasurer of the Benevolent, opened and closed the proceedings, and the lantern entertainment was arranged by Mr. T. E. Freshwater, the lantern itself being under the able management of Mr. R. R. Beard.

A Lesson of the Exhibition.—The 1892 Exhibition of the Photographic Society of Great Britain is now a thing of the past, and the unanimous opinion of art critics is that it was the most successful ever held. In it the artistic element was infinitely more pronounced than on any former occasion. Notably was this the case with the majority of the prints of a sepia tint on rough-surface paper. As with painters, so with photographers; when success is attained and praise awarded there is often a tendency to overdo the thing. Now, it would be regrettable if this were done in the direction just referred to. For years past we have advocated the use of matt and rough-surface paper for the higher class of work; but there is a limit to its application, and there may be a question whether that limit has not now been reached, if in one or two instances it has not been overstepped. It must be borne in mind that a surface which is admirable for a picture say fifteen by twelve, may be far too coarse for one of the quarter-plate size. In determining on the surface of the paper, the size of the picture and its character should be taken into consideration.

A Museum Wanted.—Last week the remaining stock of Mr. J. Werge, who has retired from business, was disposed of by auction. As Mr. Werge was not only one of the oldest photographic dealers, but is one of the oldest of living photographers, it may be surmised that amongst the collection was some of the earliest of apparatus of the purpose of which the majority of those who saw it were entirely ignorant. It was rather amusing to overhear the conjectures of two or three evidently modern amateurs as to what the sensitising box, mercury box, and buffs of a Daguerreotype apparatus were for, or how they were used. Apparatus and appliances of the earliest period is year by year becoming rarer and rarer. Therefore, when such a collection as this is put upon the market it should be secured and deposited in some place where it could be seen by photographers. Such a collection would not only prove interesting to future generations, but also to the present, as evidenced last week. We are quite aware that there is a small collection of ancient photographic apparatus in the Science and Art Department, South Kensington, but it is stowed away in a remote top gallery, and we doubt if one per cent. of those interested in such matters know of its existence.

Blood Albumen.—When albumenised paper has an offensive odour it is imagined erroneously by some that it must necessarily be prepared with blood albumen. A case was tried in one of the Law Courts recently, which was interesting as showing the scale upon

which this albumen is made, and some of the purposes to which it is applied; also the price at which it is sold. The action was brought by the manufacturer to recover the value of four tons of the albumen at threepence per pound. The defence was that the bulk was not equal to the sample. Experts were called on both sides, with the usual conflicting results. It was admitted by the manufacturer that the albumen was of inferior quality, and that the smell was not good, hence the low price at which it was sold. He said the price usually paid for good albumen was 7½*d.* or 8*d.* a pound. Two samples were handed to the learned judge, who at first could detect no difference between them in the smell, but afterwards he said he "thought sometimes one smelt worse, and sometimes the other." In the end he decided in favour of the plaintiff. The albumen was to be used in this case in calico printing, for which large quantities are required. Blood albumen is also largely used in the clarifying of sugar. It was stated that it required the blood of about 2500 bullocks to make one ton of blood albumen. If this be correct, but little over a pound of albumen can be obtained from the blood of a single beast.

Photographing an Image by Reflection.—Mr. F. J Smith, of Oxford, writes to *Nature*: "The great utility of spark photography for obtaining time records of quickly moving objects must be apparent to all who know the experiments of Mr. C. Bell, Professor Boys, and Lord Rayleigh. By means of spark photography the shadow of any object, such as a jet of water, a flying bullet, or a broken soap film, can be produced with perfect definition. The shadow of the moving object illuminated by an electric spark is thrown on to a sensitive plate in a dark room, and the plate is developed in the usual manner. The process of spark-shadow photography will be found, I believe, of great service in physiological research. With a view to try this, I attached a long sensitive plate to the traversing carriage of a chronograph; the moving carriage closed and opened the primary circuit of an induction coil at prearranged equal intervals of time. In front of the moving plate a frog's heart was placed in a slit on a screen; at each break a shadow of the heart was thrown on to the plate by means of the induced spark. By this means thirty positions of the heart were registered; the pictures were all sharp and clear. I have also used the same method for photographing the movements of insects. Since these experiments, which I showed during the University Extension Meeting in Oxford this year, I have made several attempts to get spark photographs of the front view of objects (not their shadows). In my first experiments the objects were illuminated by an electric spark, the image being received on a plate in an ordinary camera. I found that so much useful light was shut off by the lenses, that only a dim picture could be produced. A quartz lens was next tried, and the results were rather better. I then determined to use no lens, but in its place a silvered mirror. A concave reflector, made by silvering a concave lens of about 10 c.m. diameter, was so placed that it reflected the image of a white-paper star 7 c.m. diameter, revolving about sixty times in a second, on to an ordinary photographic plate, the total length traversed by the light being 80 c.m. The star was illuminated with a spark exactly similar to that used in the previous experiment; on development, a good picture of the star came out. The reflector was neither well made nor well silvered. The idea was suggested by observing some spark photographs I obtained of waves on the surface of mercury reflecting light. When a steady light is used, a photograph of any object is readily obtained by reflection from a suitable mirror. Probably a steel surface would be best. The mirror and plate were placed in a long box provided with a hole at one end, through which the light reflected from the object passed. A few experiments made on living objects to test the time of exposure in reflection photography showed that, in order to avoid over-exposure, a very rapid shutter must be used."

HOW SOLIO PAPER IS MADE.

ACCEDING to our request to witness the preparation and packing of the Solio paper of the Eastman Photographic Materials Company, Limited, we were permitted to visit the Company's large factory at Wealdstone, Harrow.

We very well remember the first visit we paid, not so long ago, to the works, at that time in an inchoate state, for the builders had not got much over the first story. The roads in the immediate vicinity were in such a state as to prove almost impassable, conveyances being sunk half-way up to the hub. *Now*, asphalte pavements and the hardest and smoothest of roads attest the influence of the Kodak factory (as it is locally called) upon the local authorities, who recognise that there is an important industry in their midst, and one which it is worth their while to encourage as far as lies in their power.

There are, in reality, two factories, end to end, separated only by the engine-houses, and each three stories in height. As an immense quantity of water is a daily necessity, the Company some time since rendered themselves independent of the usual sources of supply by sinking an artesian well on their own premises, which amounts to seven acres or thereabouts. One of the two factories mentioned is mainly devoted to the manufacture, output, and printing of sensitised or Solio paper, the other exclusively to that of films. In the former are located the negative, developing, and printing departments, in addition to the offices and stock-rooms.

In the Solio coating-rooms are to be found huge rolls of paper, specially manufactured for this purpose. One of these rolls is lifted up to its suitable support, and, having been unrolled to a sufficient extent, its end is brought under the domination of silver-coated rollers, and caused to pass across the surface of the gelatine emulsion with which it is to be coated. The machinery is then started, and the paper is coated, equalised, festooned for drying, dried, and finally brought out at the other end of the drying-room in a state of perfect dryness, without having once been touched by the hand.

The mechanism by which all this is effected is of the most remarkable kind, seeming as if, when once started, it did all the thinking that was necessary from the immersion in the emulsion up to the stage at which an attendant, with hands encased in white gloves, supplied it to another machine, by which, and with the aid of automatic guillotines, it eventually was presented as flat, cut-up sheets of various sizes, ready for transference to another department.

The Solio paper which we saw coated was twenty-four inches wide, and it was coated at the rate of about fifteen feet per minute, a *mile and a half* being the present output per day. It is all dried, cut up, and packed the same day as made, and is shipped off.

In the examining and packing-room we saw a whole regiment of young ladies, deftly submitting each sheet, small and great, to an electric-light lantern, faced with yellow glass, by which the slightest spec or imperfection, if such existed, could be at once seen. During our visit to this department no sheet was observed to come under the ban, but we were told that all such, when discovered, are summarily rejected and subjected to a further retrimming, in which the portion containing even the tiniest of spots is relegated to the waste room.

Mr. J. B. B. Wellington, the chief of the factory, who acted as our guide, informed us that they insisted from first to last on the sensitised paper or films never being touched by the ungloved fingers, as it was a well-known fact that the exudation from even the cleanest hands set up an action on the sensitive surfaces which, sooner or later, proved detrimental, and hence the insistance upon the employment of gloves in all departments involving contact with such delicate surfaces. The result of this was all that could be desired, as they never experienced any stain from this source.

The same care was taken in the encasing of the cut sheets into the envelopes in which they are sent out. These envelopes, for the retail consumer, contain, as is well known, a certain number of sheets, which, no matter how large or small the size, is sold at a similar price per packet, based upon the area of the paper contained therein, so that a packet containing only a few sheets equals with a wonderful degree of precision another containing a large number of those of smaller dimensions. These envelopes are all made on the premises, being cut out by machinery and closed by hand labour. In no adjoining room were being made the boxes in which the sensitive films for roller-slides are packed. The great care taken in ensuring uniformity and perfect equality throughout, coupled with that scrupulous cleanliness which was apparent at every stage, appeared to us to be a healthy outlook for the users of the productions.

Before leaving, we were privileged to examine the adjacent factory devoted to films, and in passing through some of the storage and

chemical rooms we witnessed the whole operation of dissolving gelatine from a stock of three tons, which was on the premises at the time. The emulsion is mixed fifty gallons at a time in a tank, from which it is drawn by means of a four-way tap into reservoirs placed below. Concerning the way in which the emulsion is washed by engines working automatically, it would prove of interest to such a limited portion of our readers that we shall make no attempt to describe it, more especially as to do so would involve the necessity of making drawings, which, in the dim light prevailing there, it would have been impossible to make. We saw, however, a huge centrifugal separator in this room, and through this all the emulsion has to pass. A batch of emulsion having been made and tested by the Hurter & Driffield system, to which Mr. Wellington gives preference over all others, it is conveyed to the cold storage-room, where, by suitable refrigerating apparatus, the temperature is kept several degrees below the freezing point summer and winter, thus rendering atmospheric influences altogether inert upon the precious productions stored therein.

What interested us probably more than all the rest was the preparation of the flexible films with which the firm's name is now so intimately associated. Twelve plate-glass tables, each eighty feet long by three feet six inches wide, and occupying two floors of the factory, form the basis on which the celluloid is made. Eight men were in attendance in the conducting of this. First of all, each table was closely examined to see that it was absolutely clean; but, as if to render assurance doubly sure as regards this, a long plush brush, the width of the table, was placed in supports immediately in front, and forming part of the coating machine, a reservoir in which was then filled with an oily-looking fluid by the attendants. This being done, and everything now being ready, a lever was pressed, and the steam-engine did the rest, for the coating apparatus at once commenced to move with a unform pace towards the far end of the table, leaving a beautifully even, but still fluid, film behind it. Arrived at the far end of its eighty feet of travel, the "button" was again pressed, and the engine was stopped for a few moments until the attendants had lifted the coating machine to the next table, where the reservoir was once more charged from vessels like those by which milk is sent to town per railway, after which all went on as before until the twelfth of the eighty-feet tables had been coated. When quite dry, and without any great delay, the celluloid was coated with emulsion in somewhat like manner, but in darkness so dense as to be almost painful, although relieved by a feeble glimmer of red light.

By special means, a difficulty occasionally encountered by some amateurs has here been entirely got rid of; we allude to the liability of a celluloid film when being stripped from glass giving an electric spark, and thus damaging the delicate bromide superstratum. The means adopted by the Company for the prevention of this have proved quite effectual.

At the time of our visit there were 120 people employed in this industry.

CONTINENTAL NOTES AND NEWS.

The World's Photographic Press. — According to a German contemporary, there are eighty-two photographic journals in existence throughout the world: France having 19, Germany 15, America 13, England 12, Italy 5, Holland 3, Spain 3, Belgium 2, Russia 2, and Sweden, India, Australia, Finland, Portugal, Switzerland, and Japan 1 each.

Detaching Gelatine Negatives from Glass.—Herr Liesegang's method of detaching gelatine films from the glass supports without employing the hydrofluoric acid plan is to introduce between the gelatine and the glass carbonic acid gas, which will effect the separation. The negative or positive, after development, &c., is plunged into a bath made feebly acid with either citric, hydrochloric, or sulphuric acid, and then, without washing, is placed in a concentrated solution (25 to 30 per cent.) of carbonate or bicarbonate of soda. The carbonic acid gas thus formed puffs up the gelatine, which can then be easily removed. The film undergoes some enlargement, which could probably be obviated by a bath of absolute alcohol, and when dry the film is perfectly flat, and can then be attached to a collodion or gelatine support, as may be desired.

The International Congress.—The next meeting of the International Congress on Photography will take place in 1893 at Geneva, when the work of the Congress assembled last year at Brussels will be resumed.

The Dangers of Developer Pastilles.—In reference to the growing popularity of developer pastilles in Austria and Germany, M. H. Fourtier, in the *Photographic Gazette*, endorses a former protest of M. Davanne against the eminently dangerous forms given to these photographic products. Developer and other pastilles in these engaging shapes are likely to be mistaken by children for sweets, and thus possibly cause them irreparable damage. Perhaps this may act as a note of warning to amateurs using these pastilles to keep them out of infantile reach.

M. Lippmann's Experiments.—At the last meeting of the Paris Academy of Sciences some coloured photographs of the spectrum on albumen and bichromated gelatine, by M. G. Lippmann, were exhibited. It was stated that albumenised and gelatinised plates soaked in bichromate of potash may be employed for photographing in colours. They are used like silver-salt plates, being placed so that the mercury is in contact with the film. The colours will appear immediately after immersion in water, which develops and also fixes the image. It disappears on drying, but reappears as soon as the plate is soaked. The colours are very brilliant, and visible at all angles. Those of gelatine plates are brought out by simple breathing. The theory is analogous to that of silver plates, the maxima and minima of interference producing hygroscopic and non-hygroscopic layers with varying refractive indices.

Gelatino-chloride Papers and their Keeping Qualities.—M. Ducom, who has devoted a great deal of labour in the investigation of the properties of commercial gelatino-chloride papers, says that, in order to make a paper which will keep in stock for a period of two or three months, it is necessary that the emulsion should be strongly acid. Paper coated with neutral emulsions, however, tones more readily, while acid emulsions have a tendency to give greenish-black tones. M. Ducom quotes M. Maurice as recommending the following method of toning. The prints, without washing, are immersed in a solution consisting of—

Alum	20 grammes.
Common salt	10 „
Chloride of gold (a one per cent. solution)	10 „
Water	1000 „

The prints tone in this in five or six minutes, and, after washing, are placed in the following:—

Hyposulphite of soda	250 grammes.
Nitric acid	4 „
Alum	20 „
Ammonium sulphocyanide	20 „
Lead acetate	3 „
Water	1000 „

The precipitate redissolves in a day or two, or the solution may be filtered after ten or twelve hours. The nitric acid is said to keep the whites clear.

Aluminium Chloride in Gelatino-chloride Toning Baths and with Amidol.—Herr Stolze recommends aluminium chloride as a good substitute for common alum or chrome alum. The same gentleman also employs it with amidol for developing gelatino-bromide prints in order to harden the gelatine, adding a volume of aluminium chloride, 1 : 100, equal to the volume of the developing solution. Development is thereby slowed, but more detail is said to be obtained, and the prints, after development, will stand a comparatively high temperature of the wash water—higher, in fact, than if aluminium had not been employed.

Para-amidophenol Citrate.—A solution of citric acid is, according to Liesegang, an excellent solvent of para-amidophenol—ninety-seven grammes of the latter being soluble in two hundred grammes of the citric acid solution of equal parts, the para-amidophenol being added little by little at a temperature of 18° to 20° C. The citrate of para-amidophenol so formed is employed as a developer in the following proportions:—

Para-amidophenol citrate (concentrated solution)	1 c.c.
Sodium sulphite (concentrated)	4 „
Sodium carbonate	5 „
Caustic potash (ten per cent. solution)	2 „
Water	50 „

This gives dense blue black images full of detail, the image, with normal exposure, appearing in about ten seconds. Brown tones are obtained if the para-amidophenol citrate is rendered alkaline with caustic potash. The citrate and sulphite are also applicable in aqueous solution as a developer for partly printed images on gelatino-chloride.

Matt Aluminium.—In order to impart the appearance of matt silver to metallic aluminium, the object is plunged, for from fifteen to twenty seconds, in a ten per cent. warm solution of caustic soda saturated with common salt. It is then washed and brushed, reimmersed in the same bath for half a minute, and finally washed and dried in sawdust.

AN INDIAN STUDIO.

A CORRESPONDENT forwards us the following particulars of Mr. Shapoor N. Bhedwar's studio:—The name of Mr. Shapoor N. Bhedwar must have been deeply impressed upon the minds of all those who have taken an interest in the exhibitions of photographs in England during the last three and a half years, and as we happened to be recently in Bombay for a few days, we felt we could not lose the opportunity of calling upon him and seeing for ourselves not only his earlier work, but also what further pictures he had in hand for future exhibitions; we further were sure that Mr. Bhedwar's many friends in England would be glad to hear what he was doing in his own home.

We have taken the greatest interest in all that appertains to photography for very many years, but having been resident in India for the past twenty years (with the exception of 1887), we have not had the chance of seeing those pictures for which Mr. Bhedwar was awarded so many valuable prizes—valuable not perhaps so much from their intrinsic value, but from the fact that they represented well-earned victories over the leading English photographers.

The studio is situated in the fashionable quarter of Bombay, on Cumballa Hill, whence a magnificent view of the town and harbour is obtainable on clear days, which, by the way, are much more numerous in India than in England.

The reception room has its walls covered by the best productions of Mr. Bhedwar, prominent among them being the series *Feast of Roses*, which alone secured some six prizes, including two championship gold medals and a silver cup. The room has more the appearance of an art gallery than an ordinary photographer's reception room; small work being conspicuous by its entire absence, and photography being represented by pictures 15 × 12 and thereabouts, all on plain paper, and some magnificent enlargements on bromide paper and opals, some of these being beautifully finished in colours.

The next room contains a collection of pictures taken by the well-known H. P. and R. W. Robinson, the former being represented by such photographs as *A Merry Tale* and *When the Day's Work is Done*, and the latter by a selection of his *Artists at Home*.

The studio is a fine room very handsomely furnished and contains very little photographic apparatus, one or two backgrounds and a few accessories being all there is to show its use. The dark room is large and suitable to the climate, being open at each end.

After we had been conducted over the whole establishment, Mr. Bhedwar was good enough to show us some of the work recently finished and some still in course of production; of those completed the leading series was *The Consecration of a Parsee Priest*, which we believe is now on exhibition at the annual show of the Photographic Society of Great Britain, in London.* In this series Mr. Bhedwar shows much artistic feeling, the posing being well marked in intention and his manipulation of light and shade very delicate and correct.

A series of pictures of a Hindu lady was simply delightful, but being made for a private patron, they are unfortunately not available for public exhibition. Should Mr. Bhedwar succeed in getting permission to show them, they would, we are sure, be hailed with acclamation; they show what an artistic photographer can make of ordinary portrait work.

Mr. Bhedwar is now engaged upon some pictures for next year; they are to be entitled *The Amir's Daughter*, and when finished will be found quite up to the general high average of his work. In this series he is making his first trial of combination printing, and we had the opportunity of seeing one in progress.

So far as the ordinary work of a photographic studio is concerned in the production of *carte-de-visite* and cabinet portraits, there seems little at present, Mr. Bhedwar apparently laying himself out for a higher class of work; but assuredly as the fact becomes known to the residents and visitors of Bombay that an artist of Mr. Bhedwar's powers is living in their midst, the amount of work that will fall to his share will rapidly increase.

We do not think that the ordinary run of photographers will be injured by Mr. Bhedwar's advent in Bombay, as there is not a very great demand at present for such works of art as he produces; but we think there can be little doubt that it will very soon become the fashion for the beauty, rank, and wealth of Bombay to be immortalised by Mr. Bhedwar's camera, his portraits being not merely likenesses but also "pictures."

Mr. Bhedwar apparently used no glazed surfaced paper, but confines himself solely to prints on plain paper toned with platinum, which process gives his productions every chance of permanence, even in such damp heat as Bombay enjoys.

In conclusion, we may state that even without any wish to be photographed oneself, one is amply repaid for a visit to Mr. Bhedwar's studio by a sight of the lovely pictures.

* If these pictures were intended for the Society's Exhibition, it would be interesting to know why they were not there.—ED.

THE AMATEUR QUESTION.

[Dundee and East of Scotland Photographic Association.]

THE feeling may not be universal, but there can be no doubt that, in some quarters at least, a certain amount of animosity is springing up between the professional and the amateur. Those who study periodical photographic literature cannot have failed to have come to the conclusion that the relations between the professional and the amateur are strained. This is a new and unwelcome condition of things, and, as this Society has in a great measure lost hold of the professional element, it might be profitable to inquire whether this is in any way due to the same causes that have led to the general estrangement of professional and amateur.

I am fortunate in a large circle of friends, amongst both professionals and amateurs, and have heard both sides of the question debated, with great freedom sometimes. Like most debated points, there is a good deal to be said on both sides.

The question hangs more or less on statements which are themselves either uncertain, or, at best, matters of opinion. In such cases the decision should rest with the *preponderance* of opinion, since there is no higher tribunal to which to appeal.

Under these circumstances, while I shall certainly give my own views on the matter, it is to be understood that I make no claim beyond introducing the subject. I have heard it said, Why discuss the point at all? The amateur is entirely independent of the professional, and cannot be injured by him; let him rave.

This is, to say the least of it, not a generous attitude; and, since the professional makes a distinct charge against the amateur, it surely is right that he should look after his character.

The allegations are, firstly, that professional photography is on the decline; and, secondly, that amateurs are in great measure to blame for this. Should the first allegation fall to the ground, the case against the amateur necessarily breaks down, and there is an end of the matter. On the other hand, should the first allegation be sustained, it then becomes necessary to determine if the amateur is to blame for this; and, if so, how far he is justified in ruining the professional for his own sport.

IS PROFESSIONAL PHOTOGRAPHY ON THE DECLINE?

The first question, then, is, Is professional photography on the decline?

At the very outset we are met with a difficulty here. How are we to determine this?

A very little consideration will show that individual evidence is of no use here. Brown, Jones, and Robinson may complain loudly that they do not have the same business by half that they once had, but this may only mean that the business has gone elsewhere. Take a further case

Suppose, for argument's sake, that the whole of the businesses in a locality have suffered; is it not possible that this is due to causes acting on the general prosperity of that individual locality, and not on the photographers only? We have really had no evidence whatever that professional photography is on the decline.

If we could determine the amount of capital invested in professional photography (the only sure test), I am very strongly of opinion that we would find that professional photography was never in a more flourishing condition. My personal observation leads me to believe that perhaps there may be *fewer* businesses in a flourishing way; but, on the other hand, look at the palatial premises reared on the most valuable sites by the favoured few!

I know it to be a fact that some of our modern studios turn over more money in a month than half a dozen average businesses of a dozen years ago would have done in a year.

In point of fact, photography, like every other business nowadays, requires capabilities not found in the herd. The day has been when the shutters could be put on and the door locked while the proprietor enjoyed a comfortable dinner at his own fireside; but it is so no longer. There are fortunes making yet, even in photography, by those who have the required capabilities, and the race is generally, if not always, to the swift, more so than ever in our day.

In not a few instances the falling off of trade is apparent, not real.

Dry plates, ready-sensitised paper, retouching given out, enlargements given to professional enlargers, reduce the hands in an establishment, and the bustle, perhaps also the profits, even where the trade is as good as ever. While I am ready to admit that business is not, as it once was, evenly distributed over the many, but rather conserved to the favoured few, I am decidedly of opinion that the total amount done is as great as ever, and the capital employed in proportion.

If this is so, it follows that the case against the amateur breaks down, at least so far as he has been supposed to injure professionals in general.

But may there not be many *individual* instances in which amateurs have injured the business of the professional? If this occurs to any extent, the question deserves discussion; and, in order to open it, let us admit, for argument's sake, that it does.

Do Amateurs Injure Professionals?

This brings us to the second question proposed for discussion, to what extent is an amateur justified in carrying on his sport to the hurt of the professional?

An amateur may be defined as "one who does for sport what another does as a means of livelihood." If this definition be fairly correct, it follows from this that the moment remuneration becomes the motive the individual has lost his amateur status. Whatever he becomes, he ceases to be an amateur.

The question, so far, is easily settled. Unfortunately, very few care what precise appellation they go under. If it were a mere matter of name nobody would be a whit the better or worse whether a man was entitled to call himself an amateur or no; but it is more than a mere matter of name. In whatever profession or trade, an amateur has certain privileges, and a professional certain responsibilities. It is manifestly unfair that any one posing as an amateur should enjoy all the privileges, together with a proportion of the emoluments, of the professional, however small, without sharing in the responsibilities.

I know there are many who think that they are entitled to make their expenses out of the thing, if nothing more. For my part, I don't see what right any one has to take up a pastime the expenses of which he cannot meet, and he certainly has no business to pose as one who can afford to spend his money this way when, in fact, it is not costing him a penny. I am imputing motives to no one; this is only my way of thinking.

Between the undoubted amateur, who pays for everything and gets in return only the sport, and the poor struggling labouring man who eks out a scanty livelihood by photographing the coalman's horse or the grocer's van of a Saturday afternoon, there are numberless degrees. The question to settle is not the amount of moral delinquency, but the essence of it in each case.

Professional photographers have done nothing for photography; it is not on this account that we would say, "Hands off!" The whole question is surrounded with difficulties.

It may be asked, "Because A and B determine to earn their bread *entirely* by photography, is that any reason why C should be debarred from *partially* earning his bread in this way?" If the amateur were stealing a march upon the professional by appropriating his inventions, there might be some reason for crying "out" on him, but it is a well-known fact that every invention and discovery in photography has been from the unselfish and enthusiastic amateur.

Much has been said about the generosity of the professional to the amateur. I have gotten much kindness from them, but I have never found them very free to communicate any of these little tit-bits of information discovered by themselves, nor do I blame them; it is not sport they are after, but bread, and in these days of competition one can't afford to burn the midnight oil and then make his discoveries common property. It is easy for the amateur to hurry his little inventions off to the journals; it will take no bite out of his mouth.

As you will see, I am taking up no hard-and-fast position, but rather saying what can be said on both sides. I sometimes feel inclined to ask why should professional photographers cry out so much against the amateur. Does every trade and profession not suffer just in the same way? In my own profession we every day see people put their lives into the hands of amateurs, generally with the very best results so far as the legitimate practitioner is concerned, for it means more work for him in the near future.

Professional Photography not on the Decline.

But the professial photographer himself is not over-particular. Does he not sometimes encroach on the picture-framer quite frequently? And it is just this class of man who is crying out against amateurs.

Having so far opened up the subject, I would make way for the discussion by giving the following opinions:—

Professional photography is not on the decline; there is more capital invested in it than ever.

To succeed nowadays money must be invested freely, the very best talent secured, and the very best business principles practised. All of the professionals engaged in the business now have not these requirements; therefore some of them are feeling the pinch.

The idea that amateurs are seriously affecting the professionals is laughable. Is there one in our large Society who knows any amateur doing work enough to damage any professional?

Admit that, at rare intervals, some poor devil picks up a job of a Saturday afternoon, and gets a shilling or two for it (and, personally, I know of not one such case), do any of you believe that this happens to any serious extent? Do you not rather think, with me, that the large businesses of the day are swamping the small, and that this is the *great* factor against them, not the amateurs?

So far as I am personally concerned, I hope I would do as I would be done by, but it is not always easy to determine whether or no any one is to be injured by certain actions. Professionals are apt to think that everything done by the amateur is lost to them, but they forget that much of the work done by the amateur, even where he degrades himself and sells his productions, would never otherwise be done at all.

Where an amateur takes a commission, where he knows the job *must* be done by the professional if he himself refuse, I suppose we are are at one in saying he acts meanly. "Live and let live" ought to be the motto with every one.

"When is an Amateur not an Amateur?"

During the summer that has passed I spent a fortnight in an obscure corner of the West Highlands. Receiving much kindness, I had a family group taken at the cottage door, and have since sent them one small copy in a frame. The gratitude of the simple country folks found expression in a gift to me of far greater value than the little picture I made them. Although I have not received money, I have received something which is its equivalent. Have I lost my amateur status? I certainly did not take the picture for my own sport, but deliberately for their benefit. Was this pure amateurism? Then, while I got no money, I certainly received remuneration in country produce. Am I still an amateur? I defrauded no professional.

The little clachan is thirty miles from a studio, and my host and hostess would have lived and died in all human probability, but for my visit, without having been photographed.

Those gentlemen who decry the amateur so strenuously have generally a curse or two for the quality of his work also. This, to my mind, is their salvation if it exists, for who would give the amateur good money for his vile productions when they can get so much better from the professional? Does the argument not seem to say that, bad as the amateur work is, it is at least as good as what we get from the professional, therefore we will go to him?

Let the professional turn out work such as he should do, and surely the amateur "trash" will have no charms for any one. I don't know if every amateur has the same experience as I have, but I knw that the portraits which I do of my friends always seem the work of a madman to them; this, mind you, when I have succeeded, in some measure, in doing something which seems to me original and good.

The work of the amateur and the work of the professional ought to be

on entirely different lines, with different aims and aspirations. There is not now, and never will be, competition between the amateur and the professional, let them say what they like. No one who takes to photography with presumably artistic tendencies in him will ever continue to sink his artistic perceptions by working to please the public taste unless he has to earn his bread by it, when, of course, one must produce what he can sell.

Those benighted individuals who are clamouring for a price for the amateur and another for the professional will succeed in demonstrating their ignorance of John Stuart Mill, but nothing more. A demand such as the amateur of our day can raise will be met, and that at prices current, neither more nor less. Those firms declining to supply the wants of the amateur at market prices just because he is an amateur will cause a rearrangement of business in which they will be out of it, nothing more. I should advise its being tried on a *small* scale to begin with. I deplore the want of business which many are complaining of, but, being an amateur, I do not take kindly to the remarks which appear from time to time in the photographic journals over the names of certain of the profession. The amateur has a just cause, or I have been particularly fortunate in my amateur photographic friends. J. K. TULLOCH, M.B.

COPYING OLD PORTRAITS.

[Anthony's Bulletin.]

THE copying of portraits, particularly portraits of deceased persons, is a lucrative branch of regular photographic business. Aside from the money consideration, it is also well worthy of attention from the humanitarian and historical standpoints. I believe the latter to be sufficiently well understood and admitted to require no further mention.

The expression "copying portraits" may be made to include the photographic treatment of vast varieties of pictorial matter. Supposing that the photographer was commissioned to copy a quantity of originals in the form of engravings, etchings, drawings or the like, the task would present no great difficulties from the photographic side. The chief thing to be seen to would be the condition in which the originals were. If the engravings had been kept flat, as in portfolios or frames, and were free from the yellow marks of mildew appearing in patches over the paper, everything would be as simple as possible. But when the plate paper on which the older-fashioned engravings were made shows these yellow spots, or, worse yet, the brown stain from cheap backboards in the frames, which are saturated with resinous material, there will be trouble. As a matter of course, the brown portions will appear much lighter in tint on the negative, and will have to be laboriously retouched so as to harmonise with the rest, if a presentable result is desired. If work of this kind is to be done by contract, a generous allowance should always be made for the retouching.

It will sometimes happen that a lot of engravings have become soiled by their faces coming into contact with one another without any tissue paper between. In this case the ink spreads or is transferred over from the one to the other, and the lighter portions become tawny and dirty looking. Now, nothing is easier than to clean such soiled engravings, and it should be done as follows: Take a quarter of a loaf of stale bread, and having cut off the hard crust with a sharp knife, wash the hands perfectly clean, make a ball of the crumb with a few drops of water, and work it about between the palms until it is perfectly smooth and has a consistence like stiff putty. Now, pull off a portion, and, having laid the engraving flat on a table in a good light, gently pass the bread-ball over it as nearly as possible in the direction of the lines of the drawing. The dirt and ink will all come off without in the least affecting the engraving, even in its most delicate portions, and the soiled high lights will again appear as pure and clean as when the picture first left the press. No grease of any sort must have touched the bread. Plain bread made without milk or shortening, and free from even a trace of butter, is what is wanted, and the ball must not be made too wet so as to cockle the engraving. If there are marks, however, that resist this mild treatment, recourse may be had to the indiarubber eraser. This, it must be borne in mind, is not free from danger, from the fact that the rubber actually removes a portion of the surface of the paper, so that very fine lines might easily be rubbed away if much pressure was laid on. Bread crumb is merely an absorbent of the superficial dirt and dust on the picture, and is not firm enough to remove any of the surface, even when hard rubbed. If indiarubber is employed, select the finest and softest obtainable, and cut it away to a blunt point. Also have a piece of clean, fine sand paper ready, and, after every few strokes of the rubber, work off the blackened portion on the tip by a few passes on the sand paper, which will leave a fresh surface for the next application.

Portraits on ordinary albumen paper vary in quality, and sometimes will do fairly well when copied. Supposing that the original is not too much faded, and has been kept clean, it will yield a tolerable negative if exposed upon in diffused light; and care should be taken that the negative be not forced to too great density, but left soft, so as to give a harmonious print. If the original has been much handled or carried about, the surface of the paper will be soiled and perhaps roughened. Such a print may be advantageously rubbed over with the lubricator used before burnishing, or with the so-called encaustic paste of wax and turpentine, which will clean the surface and brighten it up. A few passes through a rolling-press will be a good thing; but we do not advise that the ordinary burnisher be employed, as it gives too glossy a surface, and creates an inconvenient amount of reflected light when the print is set up before the copying camera.

If permission can be obtained from the owners, the following plan is a very good one to follow, though entailing some trouble:—Throw the print into luke-warm water until it leaves the card. Have a clean sheet of thin plate glass in readiness, and pass it under the print. Then bring the two out together, and, having seen that there are no air-bubbles present, wipe off the face of the glass, and make the copy immediately before the print has time to dry. The brilliancy of the wet print, and the fact of the surface of the picture being in optical contact with the glass, will do much toward making the copying easy and successful. It may be well to say, though, that very old prints, or those made on very thin paper, should not be subjected to this rather heroic proceeding.

A really good Daguerreotype gives an excellent copy, all that is necessary being to get it in the right light. The fineness of definition and chemical perfection of a good Daguerreotype image are unrivalled by any of the achievements of modern photography, and we may remind our readers that these qualities are so prized by certain scientists that they use the Daguerreotype for astronomical photography, to the exclusion of all other processes. But the average Daguerreotype portrait, which will be brought into the gallery to copy, is no such piece of perfection. As it would hardly do to attempt the negative through the covering glass, the operator must go through the rather ticklish operation of unmounting the portrait, and, if the surface be covered with the peculiar deposit that is apt to form on it, this may be removed as follows:—After a preliminary rinse under the tap, and draining, hold it as near the mouth as possible without scratching the picture with the beard, and cover the surface well with saliva. After allowing this to remain on a short time, rinse it off, and apply a very weak solution of cyanide of potassium (say, two or three grains to the ounce) for a moment, then wash again, and dry. It is the custom of some operators to apply the saliva directly to the picture as soon as it is unmounted. Singular to say, tobacco in the mouth has no bad effect. It is possible, though, to omit this unpleasant operation. In drying, the picture should be held by one corner with a pair of pliers, and very gently heated over a spirit lamp. When it begins to dry at the upper corner, take a full breath, and gently blow on the surface until the drying is complete. Any check in the drying will create an ineffaceable mark on the picture. The final wash should always be of distilled water.

None of this trouble will be had when handling ferrotypes, or old-fashioned ambrotypes. This latter form of picture—being in fact nothing more or less than a weak negative—may often be used as a negative, and thus made to yield a very fair positive or opalotype. It might be possible, by judicious working, to make a reproduced negative with rather more vigour than the original, and obtain passable paper prints from it. As we write, we remember a case where a very successful opalotype was thus made from the original ambrotype, to the unbounded satisfaction of the owner, who was not aware that such a thing could be accomplished by photography.

The difficulties of copying paintings in oil or water colours, formerly so great, have been materially lessened by the introduction of orthochromatic plates. But I can only regard this matter as being in an undeveloped state. If a number of paintings had to be photographed, there would be certain predominating colours in each, and it could not be expected that plates prepared from one and the same emulsion would yield equally perfect results on all. For those who can afford the time and not grudge a little labour, I should advise a trial with collodion emulsion, the plate being steeped in a solution of the orthochromatic dye purposely selected for the particular colour to be dealt with. The coloured screen might be used or not, as circumstances dictated. Any length of exposure could be given, and a few carefully conducted experiments of the kind would serve as a useful guide for future work. It is hardly necessary for me to remind practical photo-

graphers that portraits in oil present the most extreme varieties of tone and colour, and that, in order to secure the full benefit of the orthochromatic principle, some selection of the dye to correspond with the work in hand should be made.

Those whose business justifies the getting up of apparatus without special regard to the expense involved, will, of course, possess all necessary appliances for holding the original in position, and getting it to centre accurately on the ground glass; but to those who work in a small way, I should like to recommend a simple thing that has proved itself wonderfully useful to me. Having accurately measured the height of the window-sill in the workroom, I procured a board six feet in length, and wide enough to hold the camera, and adapted to *one end* of it two light cross legs, of a height just sufficient to make the board level when its other end was supported on the window-sill. Having taken care to set the legs on at a perfect right angle, I could turn the whole thing upside down, and by resting a board holding the engraving to be copied against the upright legs, and setting the camera in position, perfect rectilinearity of line in the copy followed as a matter of course. The whole affair, when used in this way, was supported on a firm table. When standing in its original position, with the free end on the window-sill, I used it for holding the cameras when making lantern slides by daylight, and, when printing, to hold the frames before and after exposure. Being perfectly rigid and steady, it answered very well for trimming prints upon, if the other tables in the workroom happened to be crowded. Finally, when not in use, it could be stowed away in an odd corner, with its six-foot long upright against the wall, occupying almost no space at all. To any amateurs who may be compelled to work in small apartments, I can recommend this simple article as being very handy and very cheap.

The photographic work in copying is simplicity itself. The lens ought always to be focussed with a large opening so that everything is distinctly seen, and then a small stop put in to distribute the definition evenly. The exposure should be rather full, so as to secure all the detail in the shadows, and the development must be stopped before the lights are overdone, even if the negative comes out thin and flat in consequence. If this happens, the plate must be strengthened after fixing by any of the well-known means. Two qualities should always be sought for in negative copies—the one, freedom from granularity, caused by light striking the original at a wrong angle; and the other, softness and detail in the negative rather than strength and harshness.

ELLERSLIE WALLACE.

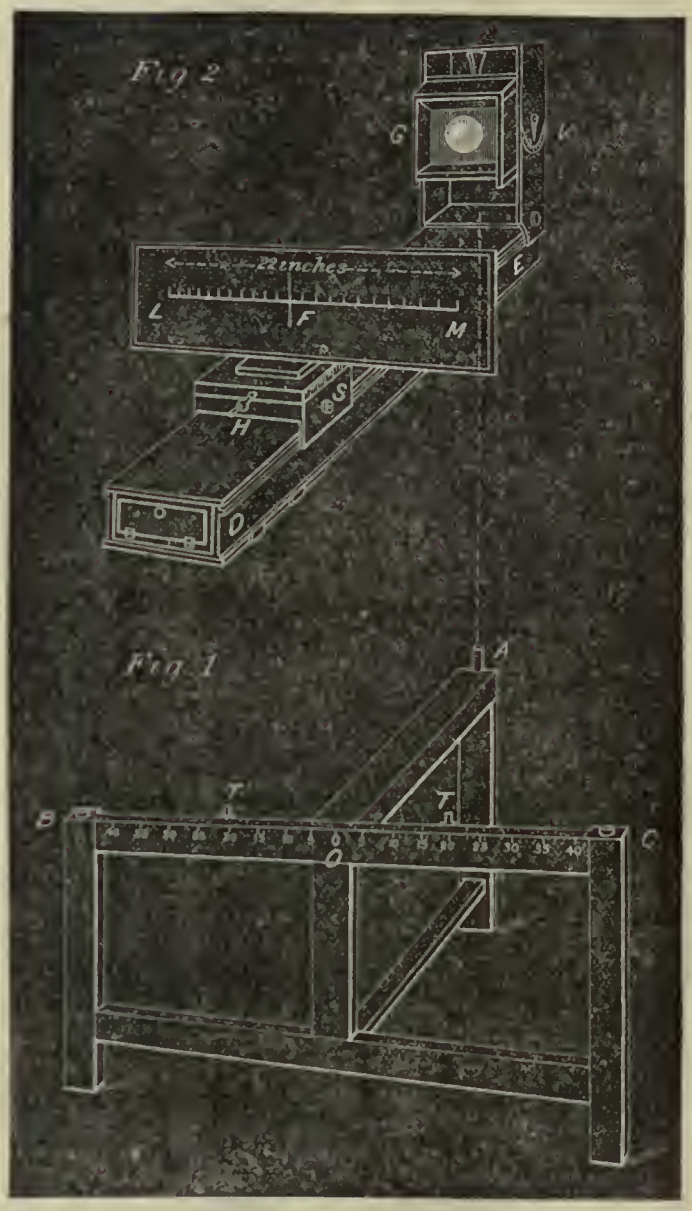
ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

8. *Flare Spot.*

THE defect known as *flare spot* consists of a bright spot or patch of light being formed in the centre of the field. To detect it, the lens is placed in an ordinary camera, which should be pointed at the sky; if the ground glass is brought to the principal focus, the flare spot is then readily visible.

For tests Nos. 9 to 16 an apparatus designed by myself, and which I have called the "testing camera," is used. It is neither an expensive nor an elaborate contrivance, and there can be no doubt that if more money had been expended a more perfect machine could have been made. Until a system of this sort has been in regular use for some time, and until it has stood the fire of criticism, experience shows, we think, that the apparatus employed is apt to be little more than a good working model of what it will become by future developments; but improvements would in this instance probably tend to increased rapidity rather than to increased accuracy, for the results obtained are now quite accurate enough for all practical purposes. Even now alterations are under consideration, such as the substitution of a sliding eyepiece on a graduated bar for the long sheet of ground glass. For the above-mentioned reasons, and because much expenditure could not be justified until it was certain that lenses would be sent for examination in considerable numbers, the Kew Committee raised no objection to the somewhat make-shift appearance of the apparatus.

The general idea of the testing camera is extremely simple, but the name perhaps is hardly a happy one, as there is no "camera" or chamber about it. Except for the absence of bellows, it may be said to consist of the essentials of an ordinary camera, which is capable of being revolved horizontally about a vertical axis passing through the lens; though it must be confessed that this description gives no idea of its appearance. The three-legged stool or bench, seen in fig. 1, represents the legs of the camera, and fig. 2 shows the apparatus that takes the place of the body; G. is the lens-holder, and LM the ground glass, both of which are capable of independent movement backward and forwards on the hollow wooden beam DE, called the "swinging beam." There is a conical brass cap or pivot, not shown in the sketch, under the upper plank of the swinging beam, underneath where the lens-holder G is shown in the sketch. The whole of the apparatus shown in fig. 2 is placed on



FIGS. 1 AND 2.

the top of the three-legged stool, the round-headed iron pin (A) passing loosely through a hole in the lower plank of the swinging beam, and fitting into the conical brass cap or pivot. The swinging beam, being thus supported by the pin A and by the long arm BC of the stool, is capable of being revolved around A as a centre. On the ground glass is engraved a horizontal line, which is accurately divided into fiftieths of an inch; this line passes through the centre of the ground glass (or through the point where the perpendicular from the lens-holder cuts the glass), and is also parallel to BC, the top of the stool on which the swinging beam slides, when the camera is in position; thus the image of an object will appear to run along the scale as the swinging bar is moved from side to side. The ground glass can be brought approximately into focus by means of the already-mentioned movement to and fro on the swinging beam, but for accurate adjustment a slow motion arrangement is attached to the movable part itself. The handle H gives the required motion, and there is a scale S, called the "focus scale," by means of which these small movements can be accurately measured. On the lens-holder there is a movement, corresponding to the swing-back of an ordinary camera

* Continued from page 713.

by which the lens can be made to revolve vertically round a horizontal axis, without, of course, any corresponding movement of the ground glass. There is a vertical arc, V, by means of which we can read off the vertical angles through which the lens is rotated. An arrangement is also supplied by means of which the lens can be moved backwards and forwards on the movable stand, thus allowing the position of the lens to be so adjusted that the horizontal axis can be made to pass through any point in its axis.

9. *Effective Aperture of Stops.*

Number engraved on stop.	Effective aperture. Inches.	*f*-number.	C.I. No.

No.	.....	.....	.....
No.	.....	.....	.....

The effective aperture of one or more of the various stops supplied with the lens is found by a well-known method. The image of a very distant object is first brought into focus on the ground glass of the testing camera; a collimator, which has itself been previously focussed on a distant object, may be used instead of the distant object; the ground glass is then taken out and exactly replaced by a tin plate with a small hole at the centre; this hole, which should be very small, will, therefore, be at the principal focus of the lens. The room being darkened, a gas burner is placed behind the small hole, and thus parallel rays, in the form of a cylinder, are made to issue from the lens towards the front. A piece of ground glass, with a graduated scale engraved on it, is now held in front of the lens, and the diameter of the illuminated disc, or section of the cylinder as seen on the glass is directly measured off as any stop is inserted in its place. Thus is found the effective aperture of the largest stop, as recorded in the Kew Certificate of Examination. The ratio of the effective aperture to the diameter is the same for all stops of the same lens, and the effective aperture of the other stops is either measured as above, or calculated from the ratio thus found. As the rays are parallel when emerging from the lens, it is evident that, if the stop is in front of all the, lenses, the effective aperture will be the same as the diameter of the stop itself

By imagining the path of the rays in the above experiment as being reversed, in which case the rays forming the cylinder are all brought to a focus on the plate, it is evident that the intensity of illumination of the plate at the centre, when focussed for distant objects, varies directly as the sectional area of the cylinder, and therefore as the square of the effective aperture as above measured. The intensity of illumination of the plate also varies inversely as the square of the distance from the point in the lens from which all the light may be supposed to emanate, that is from the nodal point of emergence. If we adopt as our definition of the principal focal length (f) of the lens the length between the principal focus and the nodal point of emergence, it is then evident that the square of the effective aperture divided by f^2 will be a measure of the illumination of the plate. In consequence of this fact, it has for a long time been customary to speak of the diameter of stops in terms of the ratios of their effective apertures to the focal length of the lens; for example, a lens having a stop with an effective aperture equal to one-tenth of its principal focal length is commonly spoken of as working with an intensity of f-10. But it has recently been found by photographers that it is practically useful to adopt a definite standard or unit of intensity of illumination in order that the different stops may be numbered in such a way as to readily indicate the different exposures required with each. Many systems of this kind have been considered—f-100, f-10, f-4, and f-$\sqrt{10}$, each having been at various times proposed as the basis of enumeration, the numbering of the stops sometimes increasing and sometimes diminishing as the necessary exposure increases. Each of these systems has met with considerable opposition from different quarters; but this is not the place to discuss their relative merits, more especially as in selecting one of them for the Kew certificates, we have been chiefly influenced by considering which has received the sanction of the most authoritative body, and which, therefore, stands the best chance of universal adoption. Judged by this standard, there can be no doubt that the recommendations of the International Photographic Congress of Paris of 1889, as endorsed by the Congress at Brussels, should be adhered to as far as possible.

The following system, which we have called the C.I. system, has therefore been adopted at Kew. The stop f-10, the effective aperture of which is one-tenth of the principal focal length of the lens, is called stop No. 1, and the exposure necessary for any subject with that stop is the unit of exposure for that subject. The other stops are numbered in the inverse ratio of the area of their effective apertures to the area of the effective aperture of stop No. 1. Thus stop No. 2 gives half the intensity of illumination of stop No. 1; and, in any case, to find the time of exposure necessary to produce the same result as with the unit of exposure with stop No. 1, we multiply that unit by the number of the stop in use. The practical rule to find the C.I. number of a stop is to divide the square of the principal focal length by 100 times the square of the diameter of the effective aperture of the stop. The principal focal length, which we require to know in order to calculate the numbering of the stops, is found by test No. 11.

The difficulty of introducing the C.I. numbering of stops will perhaps be greater in England than on the Continent, partly because, previous to the Paris Congress, the Photographic Society of Great Britain had given provisional support to another system based on f-4 as a unit. The Photographic Society has been waiting for the recently published reports of the Brussels Congress to reconsider this matter, and it may be hoped that they will join in the effort to get the C.I. system universally adopted, notwithstanding the inconvenience that must be severely felt at first by those who are therefore obliged to change their methods.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

NOVEMBER 8,—The President (Captain W. de W. Abney, C.B., F.R.S.) in the chair.

Messrs. Carpenter, Chaplin, Clulow, C. W. Gamble, Griffiths, and Dr. Grey were elected members of the Society, and a large number of nominations were read. Several presentations to the library were announced, as well as the purchase of a copy of *Sun Pictures in Scotland*, by the late Fox Talbot.

The HON. SECRETARY stated that the Lyonsdown Photographic Association (Barnet) had that day been admitted to affiliation of the Society.

ADDRESS BY THE PRESIDENT.

The PRESIDENT, in delivering an address, said that it was an innovation, or, rather, an experiment, inasmuch as it had not been done before, but it was the wish of the Council, and he thought that it had better be given then than at the annual meeting. The office he held was no mean one, and he could but recall that in the existence of the Society there were only four Presidents before him—Sir Charles Eastlake, 1854-5; Lord Chief Baron Pollock, 1855-1869; Mr. James Glaisher, who presided down to 1892, with the exception of a small break when volcanic eruptions were about, the chair being then filled by Mr. John Spiller. No small part of his (the President's) scientific life had been spent in the Society, to which he was elected in 1871. He had been editor of the Society's Journal for sixteen years, and had seen its laws twice revised. Those laws were again under revision, and when completed he thought the Society ought to be allowed to exist in peace for some time to come. They might

depend upon it that a working Society had little time for tinkering its laws. The Society chose its own Council, and he would say to the members, Trust the Council. The President remarked that it might be interesting to them if he read the names of those who formed the first and second councils, and said that the labours of those men still spoke to us. His wish was that in twenty-seven years to come, when some future President delivered his address, the work done by the present members of the Council would be as good as that of the men to whom he had referred. The Society could aspire to nothing higher than to help forward photography. They often heard that art owed nothing to science. The retort discourteous would be that science owed nothing to art. It was easier to pose as an artist than as a man of science before being found out. One of the main objects of their Society was to encourage the scientific aspects of photography, and he thought they could look back nearly thirty years with satisfaction from that point of view. It was a long road that had no turning or milestones. If there had been no turning, the road would have been a weary one, but the milestones made it less long. There had been no important advance in photography which had not been discussed by that Society, and, although it might be 1000 miles to perfection, one mile less made it 999. They, of course, would never reach that goal; but there were others that would succeed. There was no nobler aspiration than the search after truth, and photography was helping to an enormous extent in many problems. Remarking that one of the marvels of science was the action of light on sensitive surfaces, the President went on to briefly indicate the possible influence which recent physical, chemical, and mathematical science had on photography [this part of the address will appear in a future number], and concluded by remarking that no great advance would be made in photography unless theory was a little ahead of it. He thought the Society should take up theoretical subjects. He congratulated the Society on the exhibition. Some old names were missing from the catalogue, but he hoped to see them there on a future occasion. The Exhibition had been favourably noticed by the press with one exception. A critic had a free pen, and no one could find fault with the impersonality of a paper if he used it so. When an art critic was sent to criticise art, his opinion in such matters was supposed to be valuable; but one critic had expressed his opinion to a small extent on the pictures, and to a large extent on the Society. They accepted the criticism on the pictures with pleasure; and the other they could also accept because it had done no damage except to the gentleman who had penned it.

The President subsequently distributed the medals to the successful exhibitors at the recent Exhibition, Messrs. Karl Greger, R. Gay Wilkinson, W. Bedford, Colonel Gale, H. Yeo, Sawyer (Autotype Company), Hobson (Taylor, Taylor, & Hobson), being present to receive their awards, the President observing that he thought the Society could congratulate itself both on the Exhibition and the excellent way in which the Judges had executed their functions.

"Some Remarkable Properties of Silver and Gelatine."

In the absence of Mr. Howard Farmer, his brief communication on this subject was read by Mr. Chapman Jones, the Hon. Secretary. The first property drawn attention to was the catalytic action of finely divided silver in the presence of gelatine and bichromate of potash, the alteration of the bichromated salt in light reducing the gelatine to the insoluble chromated form, while the silver itself does not undergo any change. The simplest manner of observing the reaction was by placing some silver in a solution of ammonium bichromate; if the latter be of a strength of twenty per cent., the reaction was practically instantaneous. Silver bromide plates, if developed with ferrous oxalate, and plunged into a twenty per cent. solution of ammonium bichromate rendered the gelatine in contact with the reduced silver insoluble, and the images, after washing, presented the same relief as carbon prints immersed in water. The films could be squeegeed on to an insoluble surface, and developed with hot water. By heating the films, similarly reticulated surfaces are obtained on immersion in cold water. Thus they had the means of obtaining the high degree of sensitiveness of gelatino-bromide in conjunction with the effects of light on bichromated gelatine. In reference to the second property referred to, Mr. Farmer observed that, when many salts—notably the bichromates—are dissolved in gelatine, and the gelatine dried, the salts did not crystallise out, but remained in the gelatine. Dry gelatine retained sixteen per cent. of water at ordinary temperatures, and it may be heated and the water driven off. This solvent action of gelatine was quite distinct from the solvent action of water. Many other substances were readily taken up by dried gelatine—barium sulphate for instance, which could be emulsified in gelatine, and when the emulsion was dry remained in suspension, the film becoming perfectly transparent, like glass, molecular contact appearing materially to alter the physical properties of the film. With barium sulphate and other insoluble substances the effect of reticulation was most marked. Bichromated gelatine gives reticulation of a more or less greasy nature, but with barium, when the surface was plunged into cold water, the surface was quite free from greasiness.

Mr. T. Bolas said the paper opened up some new fields, and he would repeat the experiments.

Mr. T. Sebastian Davis, in regard to the transparency of the film containing barium, said the idea was almost associated with the transparency seen in the analogous case of silicate of potash in the ordinary manufacture of glass.

Mr. Chapman Jones asked whether it was a fact that nowadays in collotype printing nothing was added to the gelatine; formerly he understood that silver bromide was sometimes present.

Mr. J. Traill Taylor, speaking of one American collotyper who produced results of great excellence, said that in his case nothing was added to the gelatine.

The President observed that Mr. Warnerke several years ago took out a patent on the basis of gelatine becoming insoluble when the plate was developed with pyro. There were a good many possibilities in the use of celluloid films, and doubtless good work could be done with bichromated potash in connection with a silver salt. At Chatham last year he was able to show that printing blocks could be produced on the same principle. He was quite certain that if the gelatine film was more experimented with there were no end of possibilities which would open in photographic printing. The paper was not altogether new to him, as he had experimented on the same lines, though he was not certain about the solubility of barium sulphate. He recollected in the old days that they had a process—the Eberneum—in which gelatine and oxide of zinc gave a matt opal-like surface, which was very pleasing to look through. He had tried the same thing with sulphate of barium, and got the same result as recorded by Mr. Farmer.

The meeting then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 3,—Mr. G. W. Atkins in the chair.

Messrs. Grundy and Lorrimer were elected members.

Action of the Red Rays on Exposed Sensitive Surfaces.

Mr. A. Haddon, in drawing attention to Messrs. Bolas and Debenham's experiments with regard to the effect of red light upon a plate of haloid salt of silver that had already been exposed to light, said that an objection had been raised to the experiment in that the filtering media were not such as to allow the pure red rays only to fall on the plate. He therefore thought it worth while to make a few experiments, using instead of glass the spectrum with an electric light and a bisulphide of carbon prism. He exposed a piece of gelatino bromide paper to the light of a paraffin lamp for three seconds, another for five, and a third for ten, the three pieces being then exposed in succession to the action of the spectrum. During the exposure the light was turned on and off, the spectrum at the upper part only being allowed to act for a second. In the second case paper was exposed for six, eighteen, and thirty seconds to the paraffin light, and, on development, no difference could be discovered between the portions that had simply received exposure to the white light and those that had been exposed to red plus white. Red light, in fact, had neither undone nor increased the density of the deposit where it had acted. A similar experiment on plates yielded the same result. He had also exposed gelatino-chloride paper to the pure electric light, when it discoloured over the whole surface. He then exposed it to the action of the spectrum for ten minutes, at the end of which time there was a distinct difference in colour where the red light had fallen. Was this a chemical or physical change? In order to put this to the test he fixed one half and fixed and toned the other, and it was then impossible to see any difference between that portion where the red light had fallen and altered the colour and where it had not. A second piece of gelatino-chloride paper was next taken, and before being exposed to the action of the spectrum one-half only was exposed to the light of the arc lamp. The spectrum was then allowed to act on a considerable portion of the paper, and the other half to the bare light. Where the red light acted there was a marked change in the colour of the paper itself, which showed that there might be a physical change. He, however, doubted if any chemical change took place, as, when fixed, it could be seen that the margin of the paper appeared exactly the same where the red end of the spectrum fell.

Mr. W. P. Dando stated that he had been much mystified by obtaining different colours in lantern slides made by reduction, a light from a lantern through coloured glass being allowed to traverse that passing through the negative.

Mr. W. Bedford inquired whether, if Captain Abney's view that the action of the red rays is an oxidising one was correct, that would effect Mr. Haddon's theory?

Mr. Haddon replied that, on fixation, the same effect was obtained.

The Relative Rapidity of Different Printing-out Papers.

A communication from Mr. B. Foulks-Winks, treating of this subject, was read by the Honorary Secretary. It described experiments (the results being shown) of exposing slips of the various commercial printing papers under a negative to good diffused daylight, each strip having twelve different exposures, ranging from two to twenty-four minutes. The results of the experiments, according to the author, showed that platinotype was quickest, albumen next, gelatino-chloride next, and the ferro-prussiate slowest. Incidentally, Mr. Foulks-Winks mentioned the following toning bath for gelatino-chloride papers which he had arrived at after some experiments:—

Potassium sulphocyanide	1 drachm.
Common salt	6 drachms.
Distilled water (warm)	60 ounces.

When used add eight to ten grains of gold chloride. The bath is ready for use at once, the prints being put into it without previous washing.

Mr. W. E. Debenham pointed out that identical exposures instead of exposures proportionate to the speeds of the papers had been given. He suggested the use of scales involving the use of varying thicknesses of paper so that a geometrical increase could be obtained. The experiments did not justify Mr. Foulks-Winks's conclusions as to the gradations obtained.

Mr. E. J. Wall referred to some experiments of his own which he had undertaken with a similar object as Mr. Foulks-Winks, which he had not had time to complete. He, however, did not agree with the latter that albumen was quicker than gelatino-chloride.

Mr. J. S. Teape asked if as regular results could be obtained with gelatino-chloride as with albumen? He could not get that regularity.

Mr. A. Mackie had got regularity of results with gelatino-chloride, but only one tone.

After further discussion the meeting closed.

Hackney Photographic Society.—November 1, Mr. J. O. Grant in the chair.—A question was asked as to whether Ilford lantern plate (black tones) was a chloride or bromide plate. Mr. Beckett said it was a bromide. Mr. Wilks was nominated. Mr. Wise asked which was the best way to use amidol. Mr. R. Beckett advised using it dry. Mr. Carpenter then read a paper and gave a demonstration on *Lantern Slide Making*. He said a very great point was to get purity in the whites. He covered about one-eighth of an inch of rebate with black paper so as to detect fog. His own formula was:—Eikonogen

f

one quarter of an ounce; carbonate of potash, one quarter of an ounce; bromide of potassium, five grains; sulphite of soda, one ounce; boiling water, to ten ounces. Allow to cool. He generally diluted it with equal weight of water For warm toues he preferred pyro, and mentioned the ten per cent. formula given by Thomas. He advised plenty of good yellow light, and objected to intensification. Some lantern plates of Thomas's were then developed. Mr. GOSLING asked whether chloride plates could be satisfactorily developed with pyro. The HON. SECRETARY said he had done some.

Kensington and Bayswater Photographic Society.—November 7, Mr. Seales presided.—Mr. G. BURSNELL gave a demonstration on *The Platinum Toning of Silver Prints.* He clearly explained the difference between a print on platinotype paper and silver paper toned with platinum, the former consisting of platinum only, and the latter, however well the touing may have been effected, of an alloy of silver and platinum. He claimed that a platinum-toned print will keep longer than a gold-toned one, that in toning more of the silver is replaced than in toning with gold, and that the platinum bath will keep almost indefinitely. The bath he has found to work best is one composed of chloroplatinite of potassium, one grain; citric acid, ten grains; water, four ounces. This is an improvement over the old bath, which contained nitric acid; this last, even when diluted, having a more or less injurious effect on the gelatine. It is necessary that all toning baths of platinum should be acid. If a warm tone is desired add ten more grains of citric acid, and dilute to eight ounces of water. In printing for warm tones it is necessary to over-print more than for black tones. The fixing bath should be made slightly alkaline with ammonia. Mr. Bursnell proceeded to give his formulæ and method of preparing a paper specially suited to platinum toning. Plain Saxe paper should be obtained and first salted with the following solution:—Nelson's No. 1 gelatine, twelve grains; water, one ounce. When dissolved, add four grains of chloride of ammonium and two drachms of negative varnish. The paper should be hung up to dry, and then sensitised with the following solution:—Citric acid, fifty grains; nitrate of silver, two drachms; water, two ounces.

Putney Photographic Society.—October 24, Special Meeting. Dr. Sheppard in the chair.—Dr. Jeserich's paper on *Photography Applied to the Detection of Crime* was read by Dr. Farrar, and was illustrated by a series of lantern slides. A series of lantern slides from Australia, South Africa, and India was then shown. In addition to a high standard of technical excellence the slides had the advantage of representing views of scenery and life quite new to many of those present. The paper and slides were lent by the Central Committee of the Affiliated Societies of Great Britain, and are part of a programme provided for the use of those who have joined the Affiliation. The programme, which is of a varied character, will be found an invaluable help to Secretaries in filling up their cards of fixtures, and will be a practical inducement to other Societies to join the Affiliation.

Richmond Camera Club.—October 31, the President in the chair.—Mr. Ramsay showed Middlemiss's frame for printing slides by contact from part of any sized negative—a very simple and useful adjunct to the dark room. Mr. J. D. Gibson brought some slides which he had made on chloride plates, following the formula, &c., as demonstrated at the previous meeting. The slides were very patchy, and many of them too red in colour. He wanted to know the cause of the patchiness. Mr. CEMBRANO thought that the magnesium must have been held too close to the negative, and not moved about during exposure, thus causing uneven illumination. The subject for discussion, *Preparing Work for Exhibition*, was opened by Mr. P. ENNIS, who said that, foremost of all, the quality of the work must be the very best, and he emphasised the necessity of being original in one's style. Most workers left the printing and mounting of their exhibition work for the last moment, which was certainly not always conducive of the best results. He therefore recommended that one should start early preparing one's exhibits. A great deal of care was necessary in suitably mounting and framing, as quite a number of prints were often spoilt by unsuitable framing. Mr. WILLIAMS thought the whole question lay in a nutshell—first get a good negative, and then a good print. Mr. RAMSAY added that exhibits were often too much prepared; in other words, that too much hand work was put on them. Mr. ST. JOHN HUNT inquired which would be the best kind of frame to have. Mr. CEMBRANO replied that the frame should be simple, and that it should harmonise with the print. The object of the frame was to separate the picture from the surroundings, indeed, it might be called the boundary line of the picture. It was a great mistake to have much gold in a frame for a photograph. It was fatal to use a moul ding which, by its richness or colour, should attract the eyes before the picture was seen or thought of. Mr. ALABASTER showed a frame he had sent to an exhibition. He thought that the mounts should be made to suit the prints. He preferred toned mounts. Mr. GIBSON remarked that it was a difficult thing to find suitably toned mounts. Mr. SUCH suggested that the size and shape of the frames should be considered. He believed that some sizes had a better chance of being hung because they fitted better. He further remarked that "hangers" should endeavour to harmonise the colours of the frames as well as the tones of the prints on the walls of an exhibition. The PRESIDENT read a question which had been put by one of the members: "A negative having been imperfectly washed and put away, a mouldy deposit appears on the film after a few months. This deposit seems insoluble in water, the plate having been soaked for three days without result. How can it be cleared?" Mr. WILLIAMS advised soaking in hot water. Mr. ST. JOHN HUNT suggested rubbing the film with cotton wool. Mr. HARRIS doubted the efficiency of this treatment, as he had been unable to remove the deposit with a sponge. Mr. CEMBRANO thought that resoaking in hypo and then washiag thoroughly might answer.

West Surrey Photographic Society.—November 2, Mr. J. L. Lyell in the chair.—The subject of the evening was a paper by Mr. A. R. DRESSER, entitled *Hints on Hand Cameras.* Mr. Dresser intimated that, in his opinion, a wide-angle leus was the one to use for hand-camera work, and the camera should be one with dark slides, and not one of a magazine pattern. In concluding his remarks, Mr. Dresser said that he hoped that his hearers would not at any time bring discredit upon hand-camera work by "snap-shotting" persons under conditions which might cause unpleasantness, as many were very apt to do. An exhibition of lantern slides by Mr. Dresser was then given, some very fine sea studies, and his popular *Wild West* series being shown. A discussion followed.

North Surrey Photographic Society.—The Exhibition of the work of members and the competition for the Whitby Prize of a guinea each for the two best sets of six prints, and the Society's certificate for the set next in order of merit, were held at the last meeting on Tuesday, the 1st inst. There were sixteen entries for the competition, and the prints sent in with those for exhibition only made quite an imposing show. The competition was very keen the result of the judging showing only a difference of five marks between the first and third best sets. Mr. Lewis Wolff, under the *nom-de-plume* of "Achromatic," was awarded the first prize; Mr. H. Senier ("Columbia") the second; and Mr. W. Rouch ("Pyro") the certificate. The six prints shown by Mr. Wolff were bromide enlargements of church interiors and village scenes; those by Mr. Senier, 5×4 prints on bromide and Eastman's Solio paper, landscapes and interiors, the best being the *Banqueting Room, Haddon Hall;* and those by Mr. Rouch, bromide enlargements and marine and forest scenes. Taking the exhibits as a whole, they reflected the greatest credit upon the members, and proved that the idea to hold the combined Competition and Exhibition was fully warranted. It may be remarked that ordinary albumen prints were conspicuous by their absence, eight-tenths of the exhibits being either platinotype or bromide. Among the pictures sent in for exhibition only those by Mr. T. J. Bright were universally admired, his *View from London Bridge* and *A Pastoral Scene in Essex* being of rare merit. By the courtesy of the Committee of the West Norwood Constitutional Club, in whose rooms the Society holds its meetings, the exhibits were allowed to remain on view for a week, and many friends of the members and others interested in the art of photography have availed themselves of the opportunity thus afforded.

Blackheath Camera Club.—November 1, Mr. J. T. Field in the chair.—A lecture and demonstration on the *The Eastman Company's Products* was given by Mr. A. C. BALDWIN. The lecturer described the roll-holder and the various kinds of Kodaks, and then gave a description of the method of manufacturing celluloid films. The factory is fitted with twelve glass-topped tables, each eighty feet long and forty-one inches wide. These are coated with liquid celluloid by means of a machine, which travels the whole length of the tables, running on steel rails at the sides, each being drawn along by endless chains, worked by an electric motor. The coat of celluloid is next dried by means of fans, and then coated with the sensitive emulsion, which is spread in the same manner as the celluloid, but at a slower rate. When the emulsion is dry the film is stripped from the tables, and, at the same time, wound upon a large spool, from which it is rewound on to another similar one, passing in the mean time over a table of ruby glass, lighted from the under side by an electric lamp. During its progress it is carefully examined, any defective portions being cut out or marked. After this it is rewound on to a series of small spools, being slit by knives during the process. Each of these small spools, of course, contains eighty feet of film of the width of the spool, and this is again rewound, in the proper lengths required for certain numbers of exposures, on to the spools that are used in the roll-holders. After mentioning bromide paper, Mr. Baldwin spoke of the gelatino-chloride paper made by this firm, and called Solio paper. He toned two batches of prints, one in the combined toning and fixing bath, and the other in the sulphocyanide bath, giving some valuable hints while doing so. With regard to the depth of printing, if the prints are to be toned in a sulphocyanide bath, they should not be printed so deeply as for the combined bath, while for the latter they should be rather less deeply printed than for any other bath, such as borax. When toned and fixed in separate baths, an alum bath is necessary between. If prints are to be glazed they should be printed deeper than for a matt surface. Squeegeeing on mat, surface celluloid is recommended for matt finish, and on glass or ferrotypt plate for glazed surface. In the combined toning and fixing bath the fixing takes place first, and is complete in about two minutes; therefore, by the time the required tone is obtained, the prints are sure to be properly fixed. They should be toned face downwards in this bath. The sulphocyanide bath must be freshly made from pure chemicals, and with this very fine purple tones can be obtained, the combined bath only giving warm tones. The prints must be thoroughly and quickly washed; excessive washing destroys the gelatine. The printing frames should be filled in subdued light or in the dark room, and should be backed with waterproof paper. To mount prints that have been squeegeed on to a support of any kind, apply a thin solution of Scotch glue to the back with a piece of flannel when print is nearly dry. When quite dry, strip off print, damp mount, and lay print down. When waterproof backing of any description is applied to a print, it must not be done until print is nearly dry, as otherwise the moisture will be unable to evaporate.

Croydon Camera Club.—November 7, the President in the chair.—Mr. CHARLES HUSSEY gave a finished and comprehensive paper on *Stereoscopic Photography*, in the course of which he dwelt on the charms and pleasures of this form of view making. The lecture, which was illustrated by a number of cameras, shutters, slides, and, of course, a stereoscope, was an admirable *exposé* of the subject, and, relieved by certain humorous allusions to the failings of photographic extremists, proved highly enjoyable. The lecturer also explained how, by means of a newly devised printing frame of his own invention, stereoscopic transparency positives could be printed by contact without necessitating any cutting of the glass and subsequent rejoining.

Croydon Microscopical and Natural History Club (Photographic Section).—November 4, Mr. Sparrow in the chair.—The attention of those present was drawn to the annual *soirée* of the Club to be held on the 23rd inst. The evening was devoted to a discussion on *Hand Cameras, the Practical Advantages and Defects of Various Systems.* For purely hand-camera work, such as street scenes, the type known as the "Magazine," with a lens of short focus, four and a quarter to five inches, was considered the most convenient, whilst for general work a camera with plateholders and a longer-focus leus was preferred. The CHAIRMAN, in the course of his remarks, described a novel form of plateholder he had used for several seasons constructed from the design of Mr. Sargeant. The shutter, instead of sliding out, was hinged and laid down on the bottom of the camera, the opening and shutting being effected by a small lever outside. The advantages claimed were: that it could be made

lighter and more compact than the ordinary form of dark slide, that it could be manipulated quicker, that no light could reach the plate when in the camera, as the form of construction allowed it to be entirely closed in. It was, however, not possible to use a lens of short focus, as the lens front could not be brought up sufficiently near.

Bath Photographic Society.—October 26, Mr. Austin J. King (President) in the chair, when a paper was read by Mr. GEORGE NORMAN, entitled, *The Camera as an Aid to Archæology.*—The lecturer said his special object that evening was to show the use of the camera in making permanent record of the forms of ancient buildings, many of which were fast disappearing from the land. For this purpose there were exhibited upon the screen pictures of Irish architecture from the earliest to mediæval times, mostly from the lecturer's own photographs, taken at meetings of the Royal Society of Antiquaries of Ireland, commencing with the primitive lake dwellings and underground caves, and passing on to the beehive cells and oratories. He then described the various forms of the early Christian churches, which reached their highest development in Cormac's Chapel at Cashel, with its barrel vault and high-pitched roof of stone, and concluded with a series of illustrations of mediæval abbeys and cathedrals. The following was communicated to the Society:—"Lacock Abbey, Chippenham, October 16. I think it may be of interest to you to know that, about a month ago, I found two *dated* specimens of very early photography. The first is a very minute camera picture of an oriel window in the south gallery of Lacock Abbey, which is glazed with diamond panes. It is evidently taken from the inside, looking outwards towards the south. This photograph is of a pale violet colour, and is mounted on a piece of black paper to set it off, and that again is mounted on a piece of white writing-paper, on which is the following memorandum in my father's handwriting:—'Latticed window, with the camera obscura, August, 1835. When first made, the squares of glass, about 200 in number, could be counted with the help of a lens. The panes are still quite distinct, and could probably be counted without much difficulty. The other specimen is a photograph of a plant, taken, no doubt, from a dried specimen by application. It is dated February 6, 1839. Both these photographs must have been fixed with salt. I have many other specimens that would be of about the same period, but these are the only dated ones that I have yet found. Signed, C. H. TALBOT, Lacock Abbey. To W. M. Ashman Hon. Secretary, Bath Photographic Society."

Gosport Photographic Society.—November 3.—A well-attended meeting of amateur photographers was held here on Thursday night, when those present unanimously resolved themselves into a Society, hereafter to be known as the Gosport Photographic Society. *President:* the Rev. — Matthew.—*Vice-Presidents:* Messrs. R. E. Froude, T. E. Williams, and George Churcher.—*Council:* Messrs. H. Fisher, S. Morrish, E. Tucker, R. E. Green, Moss, and Misselbrook.—*Treasurer*, Mr. W. R. Smith.—*Hon. Secretary:* Mr. Charles H. Wright, 47, High-street, Gosport. The Society will hold its meetings in the commodious studio of Mr. James Eltringham, 46, High-street, on the first and third Tuesdays of the month until further notice, these premises having been adopted as the Society's headquarters. Conveniently arranged reading and dark rooms are at the disposal of the members. On Tuesday, the 15th inst., the President will deliver the inaugural address, to be followed by an exhibition of members' lantern slides by the aid of the limelight. Classes for beginners are in course of construction, and will be duly announced. The Secretary will be pleased to receive the names of those wishing to join. The subscription is 2*s.* 6*d.* per quarter.

Huddersfield Photographic Society.—The fourth Annual General Meeting of the above Society was held on Thursday, November 3, Surgeon-Major Foster (President) in the chair. The SECRETARY read the report and balance-sheet, the latter showing a balance in hand of 1*l.* 6*s.* 3½*d.* as against 1*l.* 17*s.* 7½*d.* on the other side last year. Mr. CLARKE then proposed the amalgamation of the Society with that of the Naturalists' Society, which, after some discussion, was carried.

Rotherham Photographic Society.—November 1, Dr. Baldwin (President) in the chair.—In view of the lantern season it was decided to form representative collection of slides of members, and to make the selection at the December meeting.

Scarborough Photographic Society.—A photographic society has recently been formed at Scarborough, with the Rev. W. T. Reeder as President, and Mr. Todd as Secretary, Mr. J. H. Rowntree as Treasurer, and the committee were chosen as follows:—Miss Augusta Woodall, Miss McCallum, Dr. Monk, Mr. J. Whitfield, Mr. Northorp, and Mr. H. Hill. The hon. Secretary, Mr. N. Todd, resides at 15, Victoria-road, and he will be glad to give any information desired, and to receive applications for membership from both ladies and gentlemen who may be anxious to help forward this Society.

Sheffield Photographic Society.—November 1st, Mr. R. J. Taylor in the chair.—The question of a Dark Room was brought before the members, when after a very heated discussion it was resolved to postpone the matter until next meeting and decide by ballot. After which a series of lantern slides was passed through the lantern by Messrs. Furness, Hibbert, Camp, and Bromley, showing the effects gained by the different developers now in use amongst photographers. Mr. J. W. Charlesworth operated the lantern.

South Manchester Photographic Society.—October 31, Mr. W. Linnel presiding.—Messrs. Hutton, Macbeth, and Wade were elected members. Mr. Lawson, of Newton-le-Willows, exhibited a new saturator invented by himself. The instrument in its present form can be placed inside the body of the lantern, as the nipple and lime-holder form part of the saturator. It is intended to burn the ordinary commercial benzoline, thus doing away with hydrogen, an oxygen bottle being alone required. Among the advantages claimed for it are its perfect safety in use, and that a more brilliant light can be obtained than with any other limelight apparatus with either one or two jets. Mr. WADE read a paper on the *Making of a Lantern Slide*, in which he gave an account of his method of making them. He said a lantern transparency required the greatest technical skill, but, when obtained, the beauty of the picture was much enhanced, and when thrown on the screen usually called forth expressions of the warmest admiration. The lecturer proceeded to give an account of the various ways by which a lantern transparency could be produced, the best negative for this work being one "full of detail, rather thin, and clear." He considered the gelatino-bromide plates the best for general use, as capable of giving a great range of tones, from black to red, transparent shadows, delicate half-tones, and as being very free from technical defects. A very thin negative is better printed on a gelatino-chloride plate. With regard to the diversity of opinion as to the best developers, he thought all developers were good if you only knew how to use them—that was the chief point. The lecture concluded with a practical demonstration, several slides being exposed and developed by Mr. Wade.

Border Amateur Photographic Association.—This newly formed Society held its first meeting at its head-quarters, Galashiels, on Friday evening, November 4. The Rev. W. Burnet Thomson, M.A., who has been appointed President, occupied the chair, and, as a formal opening of the new body, delivered an address on *The Rise and Progress of Photography*, in which he dwelt strongly upon the vast extension of its uses in all departments of life, showing there were few sections of active thought and work, both in science and art, which were not much indebted to its power of accurate recordation, in addition to its ministering to the pleasures of those who only pursued it as a pleasant hobby, or the accompaniment of a holiday ramble. At the close he was thanked for his address.

Edinburgh Photographic Society.—November 4, Mr. H. L. Blanc, A.R.S.A. (President), in the chair.—Mr. J. M. TURNBULL brought before the meeting his experiences with "amidol" as a developer, specimens of which had been distributed previously. He stated, after a prolonged and exhaustive trial, he did not find it come up to the high degree of merit claimed for it. The resulting negatives were of a thin character, and wanting in the best qualities of a good plate. The keeping quality also of the new claimant was not, or rather had not in his hands proved, a success. A few negatives and prints from them were exhibited in proof that the results scarcely equalled those obtained from other well-known developers. Eleven new members were elected. The reports of the Secretary and Treasurer were submitted, the former drawing attention to the steady onward progress of the Society and its increasing popularity. The number of members at the close of the session was stated as 392. Reference was made to the events of the past year, notably the aquisition of the handsome new apartments with dark room specially fitted, also to the very successful meetings of the Photographic Convention. The finances of the Society showed no falling off, a good balance remaining after meeting all general charges as well as the special charges incident to the new rooms. The election for new office-bearers to succeed those retiring by demission and rotation was next proceeded with. Mr. ANDERSON expressed his own and the members' regret that Mr. Blanc, their present President, had found it necessary to demit the office owing to pressure of engagements in his profession, and he hoped that even yet Mr. Blanc would consent to remain in the office in which he had been able to do so much in forwarding the Society's interest, and he moved accordingly. The retiring PRESIDENT stated that he was much touched and highly gratified by the warm display of good feeling and by the flattering compliments of his fellow-members, for which he tendered his warmest thanks, but he craved to be allowed to adhere to his resolution, and desired to propose as his successor Mr. John Moffatt, who, being duly seconded, was unanimously appointed. The following gentlemen were then appointed:—*Vice-Presidents:* Messrs. Alexander Ayton, jun., and J. C. Oliphant.—*Librarian:* Mr. Charles Fraser.—*Treasurer:* Mr. James McGlashan.—*Secretary:* Mr. J. Farclay; and, to fill the vacant memberships of Council, Messrs. Bashford, Hawks, and Blanc.

Nelson Camera Club (Nelson, N.Z.)—June 22, Annual Meeting.—The report showed that the finances were in a satisfactory condition, and that the membership had increased to eight honorary and thirty-six ordinary members. The President referred to the loss the Club had sustained by the removal of its late Secretary, Mr. F. W. MacLean, from the district, and urged members to increased efforts. During the session 1891-92, the usual monthly meetings have been well attended, and the work put in for the monthly competitions has shown that the interest in the Club has in no way abated. The annual exhibition was held on September 3, 4, and 5, 1891, and was an entire success. Between 600 and 700 pictures were on view, and were much admired. On former occasions admission had been free, but this time it was decided to make a small charge, notwithstanding which the hall was well filled each afternoon, and crowded during the evenings. On the first evening the President gave demonstrations of platinotype printing and of flashlight photography, which were attended to with much interest. The second and third evenings, lantern exhibitions of members' slides were given. This being a new departure, and the slides being principally of local interest, much appreciation was expressed by the large audiences. Mr. F. W. Holland was the exhibitor. In December, 1891, a contribution of fifty frames of photographs was sent to the combined exhibition of the Otago Art Society and the Dunedin Photographic Society, and met with much commendation from the local press, and from the visitors to the exhibition.

MATT P.O.P. PRINTS.

To the EDITOR.

SIR,—May we say in reference to your article of last week that Mr. Crooke has been good enough to explain his method of producing the admirable prints we sent you? He squeegees them downon glass in the usual way, and after mounting passes them through a rolling press.

We have tried the method you suggested, and whilst it produces capital results, it is not commercial, for the celluloid sheets are spoilt after once or twice using.

We thank you, Sir, for your impartial summing up of the question of "Gelatine *v.* Albumen," and feel we are not too sanguine in prophesying that gelatine will replace albumen in the nineties as it replaced collodion in the seventies. Such a consummation is devoutly to be wished, not only in the interests of English trade, but on account of the superiority of results.—We are, yours, &c.,

THE BRITANNIA WORKS COMPANY, LIMITED.

PHOTOGRAPHY AT THE WORLD'S FAIR.

To the EDITOR.

SIR,—I enclose a copy of an official letter received from Chicago relative to the photographic privilege at the Columbian World's Exposition, which I think will interest many of your readers. In accomplishing this much I wish to convey to our many friends on your side of the ocean, through your JOURNAL, my sincere thanks for the aid they so kindly give us. Probably further restrictions which now appear may be removed by the time the Exhibition opens.—I am, yours, &c., F. C. BEACH.

301, *Broadway, New York, October* 28, 1892.

The World's Columbian Exposition, C. D. Arnold, Official Photographer.
OFFICE OF D. H. BURNHAM, DIRECTOR OF WORKS, WORLD'S COLUMBIAN EXPOSITION, JACKSON-PARK, CHICAGO, ILLS.
October 25, 1892.

American Amateur Photographer, 239, *Fifth-avenue.*

GENTLEMEN,—Hand cameras using plates up to and including 4 × 5 inches, without tripods, will be allowed within the grounds of the World's Columbian Exposition on and after this date, on payment of a fee of two dollars in addition to the regular price of admission for each day.

Cameras using stereoscopic lenses will not be admitted however small the plate may be.—Very sincerely, C. D. ARNOLD, *Official Photographer.*

DETERIORATION OF OXYGEN.

To the EDITOR.

SIR,—There are one or two questions in the current LANTERN SUPPLEMENT which seem to call for some notice.

The first is, the deterioration of oxygen when kept in cylinders. I have used cylinders almost ever since the introduction of the high-pressure system, and have never found the deterioration spoken of by your correspondent, F. Bailey. A few years ago there was some reason for complaint as to the apparently diluted quality of oxygen being supplied, but that has for some time now been remedied, and I do not think there is now any need to find fault on that score. As for deterioration after two months, my experience has been this:—A few days ago, beginning the season, I used some oxygen for a public "show" that had been filled into the cylinder last April, the cylinder then being about half emptied, and the oxygen was, after nearly seven months, quite as good as when freshly charged, and was what I expected from past working. I think most London workers who go to the "Brin's' Oxygen Company" will bear me out in this experience. As you know, Sir, I have no interest in any oxygen suppliers, and only speak of them as I find them.

A question asked by "Operator" as to recessing the oxygen jet three-eighths of an inch in his blow-through jet, deserves just a word. Three-eighths of an inch is rather a long way in, and the result of the combination of gases so far in the tube will probably be, as I have myself found, to melt off the nose of the burner until it is of a safe length, to its detriment, of course. One-eighth or three-sixteenths at most is, I think, quite as far as he may safely go, and in this position the light will be much better than in the form of blow-through jet usually sold. But if he uses the jet for dissolving, and does not keep just a little oxygen always "on tap," he must look out for pops which may make his tubes jump about in a rather startling fashion.—I am, youre, &c.,

November 7, 1892. LIME-BURNER.

THE DETENTION OF SPECIMENS.

To the EDITOR.

SIR,—Allow me space in your JOURNAL to make a few remarks with regard to photographic assistants and their specimens. The practice of sending specimens when applying for a situation is an old one, but one which causes much unpleasantness to both employer and *employé*, and serves no good purpose; for how often after carefully wading through a pile of prints and the sender of the best engaged, who only fills the vacant situation a few weeks, whereas if the holder of a good testimonial had been engaged thorough satisfaction would most probably have followed. But the great evil of sending specimens is they get into the hands of unprincipled men, who often simply advertise for assistants in order to get prints for their own show cases. I noticed a few weeks back a correspondent complaining of not being able to get his specimens back from a firm in Australia, who I remember distinctly promised in their advertisement the return of all prints, &c., submitted to them, but they failed to keep their promise in more than one instance.—Thanking you in anticipation of inserting, I am, youre, &c., PYRO.

Birmingham, November 7, 1892.

[Why do not assistants take our oft-tendered advice (when sending specimens) to write their names and addresses on the pictures? This would prevent any misuse of them.—ED.]

CHARITABLE LANTERN ENTERTAINMENT SOCIETY.

To the EDITOR.

SIR,—I am pleased to see, by the notice in your issue of last week, that a society has been formed having such a grand object as the entertaining of the inmates of our hospitals, &c. Those who have had the misfortune to be placed in a hospital will know how long and dull the time appears to them, and how anything done to break the monotony is appreciated.

I have applied for membership, and intend to do what lies within my power to promote the objects of the Society, and I have myself already been promised help from others.

I should think that there are many who can spend an hour or two once a week or fortnight to assist in this good work.—I am, yours, &c.,

46, *Palatine-road, Stoke Newington, N.* E. DREW BARTLETT.

THE BENEVOLENT ASSOCIATION.

To the EDITOR.

SIR,—I am pleased to say that my letter in the last week's paper has brought one or two offers from employers, which have enabled us to fit good men into situations. I have one offer which is rather peculiar. A gentleman who has a good, portable saloon studio, which he has worked profitably both winter and summer up to the present, but which he is now working in the summer time only, and settling in a small town during the winter, offers to let it to a good reliable man on condition that he will retouch a few negatives for the owner, and hand him as rent all money taken over 30*s.* per week. As I have a very great number of assistants on my books, any one of whom might be willing to entertain this offer, I ask you to let me make it public through your medium, which will save me an immense amount of correspondence. One employer says that he supposes we have only "lame ducks" on our books, and others seem to have this notion. This is quite a mistake, for we have the addresses of operators and retouchers, managers, and others, who are only just out of best berths, for the men whose names are on the Employment Bureau are in no way connected with those who apply to the Benevolent for monetary assistance. We have almost all classes.

I notice in your "Lantern Notes and News," in the current issue, that you comment upon the fact that far more tickets are printed for the Benevolent Night than the capacity of the Parent Society's exhibition room seems to warrant. This criticism has been advanced by several people this year, and the fact of the high number of tickets has deterred some from purchasing. Unfortunately, the conditions of the case prevent us doing otherwise than printing far more tickets than can be used, for we are obliged to send numbers of the tickets on approval to people who kindly sell them for us, and it is only by using a disproportionately large number that we can ensure sending some to all the people who may sell a few. Even with the utmost care in sending out, we find that very great numbers are returned, and yet there are some cases where more could be sold if more were sent. For instance, the London Stereoscopic Company sold twenty-five tickets at their West End house, and said they

could have sold twenty-five more if they had had them on the last day, while several other houses, from whom we expected good sales, have returned the whole of their twenty-five; others who received ten have only sold one or two. We are extremely grateful to the Parent Society for the use of the exhibition room for one evening. Of course, if they were willing to allow us the sale of a given number of tickets for use for three or four evenings, we should be very pleased to work it on that basis.

I am, yours, &c., H. SNOWDEN WARD,
Memorial Hall, London, E.C. *Hon. Secretary P. B. A.*

AMIDOL.

To the EDITOR.

SIR,—Can you tell me why I cannot get a negative the right density with the above developer? I have exposed ever so many plates, giving short, long, and correct exposures; tried it with and without bromide, made it according to instructions, in fact have done all I can, and yet all negatives are as thin as possible.

I read and hear of such excellent results with it that I cannot understand how it is I fail.

When developing a plate, it seems to darken all over before the picture appears, and after, say, fifteen minutes, so very thin as to be useless, yet with another developer I got a good printing negative.

The stuff keeps clear enough; in fact, practically colourless.—I am, Yours, &c., W. S. P.

Liverpool, November 1, 1892.

To the EDITOR.

SIR,—I should like to inform you of an experience I have had with amidol which does not seem to have come to light before. About twelve days ago I mixed two ounces of stock solution of amidol. I diluted what I required for use with three parts of water, and added two drops of ten-per-cent. solution of bromide of potassium. It developed some landscapes splendidly, and I formed a high opinion of it. The next day I used the same solution, with a few drops of stock solution added, to develop some rather under-timed baby portraits. They also turned out very well. I then put it aside until to-day, when I thought to develop some well-exposed portraits. The solution was a pale yellow colour, but, to my surprise, no image appeared in three or four minutes. I threw this away, and mixed a fresh lot from the stock solution, which had turned a deep brown tint. This, too, failed to produce any image in five minutes. Having thrown this off, and washed the plate, I applied pyro developer, which rapidly brought out the image to good density. Having heard that amidol would develop almost indefinitely, I thought this would be interesting. My stock solution was made as directed by the vendors, viz.:—

Amidol	80 grains.
Sod. Sulp.	800 ,,
Water	8 ounces.

—I am, yours, &c., OTHELLO.
October 31, 1892.

[We shall shortly be having another article on the subject of amidol.—ED.]

EASTMAN'S FILMS—A HINT.

To the EDITOR.

SIR,—As I have found users of roller films troubled with the curling propensity of these convenient things, when printing and when necessary to dodge, &c., I can recommend them to try putting the films on glass while slightly damp, and fastening down the edges with binding strips used for lantern slides; then, when they are dry, they can be used in any way desired without trouble.—I am, yours, &c., J. S. DICKIN.
32, *Houghton-street, Southport, October* 28, 1892.

WEST LONDON PHOTOGRAPHIC SOCIETY.—November 15, Technical Social Meeting.

NORTH SURREY PHOTOGRAPHIC SOCIETY.—November 15, Mr. Lewis Wolff on *Development*.

PHOTOGRAPHIC CLUB.—November 16, Annual Dinner. 23, *Flashlight Photography*.

EXETER AMATEUR PHOTOGRAPHIC SOCIETY.—Saturday, November 12, is the last day for sending entry forms for this Exhibition.

PUTNEY PHOTOGRAPHIC SOCIETY.—November 21, *Bromide Enlargement*, by the Eastman Company. December 5, *Work with a Hand Camera*, A. K. Dresser.

MESSRS. MARION inform us that they have recently made a batch of instantaneous plates perfectly free from fog, Actinograph No. 25. They believe this to be the highest speed yet reached.

THE Hackney Society's Exhibition will be opened at 12 o'clock midday on Thursday the 17th inst., the other two days at four. Sir Charles Russell has consented to be present at the opening ceremony.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—November 17, Monthly Lantern Night. 24, Members' Open Night and *Cresco Fylma*, by Messrs. Hill. December 1, *Scenes from Ireland*, Mr. F. W. Hindley.

EVERY competitor gaining a medal in the Stanley Photographic Competition is also to be presented with a diploma of merit. The diploma itself is quite a work of art, and has been produced from a special design by a well-known firm of fine-art lithographers.

THE improvement in the attendance at the Exhibition continued to the end. The number of visitors in the past week was 1842, making a total of 8799 since the opening day. On Wednesday week, in spite of the heavy downpour of rain, there were 190 in the Gallery to see the slides lent by the Amateur Photographic Field Club.

BRIXTON AND CLAPHAM CAMERA CLUB.—The third Annual Exhibition of Photographs and Lantern Slides, comprising landscape, marine, architectural, animal, and figure studies, will be held at the Clarence Rooms, 376, Coldharbour-lane, Brixton, on Thursday, November 17, 1892 (7.30 to 10 p.m.); Friday, November 18 (3 to 10 p.m.); and Saturday, November 19 (3 to 10 p.m.). The Judges are Messrs. W. Bedford, F. P. Cembrano, and Andrew Pringle.

BLACKHEATH CAMERA CLUB.—Syllabus, 1892-1893. 1892: November 15, *Lantern Slide Development*, Mr. J. T. Field. 29, *Enlarging*, Mr. A. R. Dresser. December 8, *The Optical Lantern and how to use it* (illustrated), Rev. W. H. K. Soames, M.A. 1893: January 3, *Platinotype Processes*, Mr. S. G. Buchanan Wollaston. 17, *A trip to Norway* (illustrated by lantern slides), Mr. W. C. Chaffey. February 1, An evening with Mr. E. J. Wall. 15, Lantern Night.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—November 15, Lecture by J. P. Gibson, of Hexham, on *Bamburgh, the Farne Islands, and Grace Darling, the Northumbrian Heroine*, illustrated by 100 lantern slides from Mr. Gibson's own negatives, in the Concert Hall of the Art Gallery, Newcastle, on November 15, at 7.30 p.m. Lantern exhibition of 150 slides by eminent photographers at the Concert Hall of the Art Gallery, Newcastle, on November 14, at 7.30 p.m.

AMONG the exhibitors of apparatus in the Photographic Section of the Stanley Show are Messrs. R. & J. Beck, B. J. Edwards & Co., Sands, Hunter, & Co., Dallmeyer & Co., Lonsdale Brothers, City Sale and Exchange Rooms, Elliott & Son, W. Wray, Platle & Witt, Morley & Cooper, Autotype Company, A. J. Smith & Co., H. Park, and others. The Agricultural Hall is so convenient of access from all parts of London that this new Photographic Exhibition should be visited by all who are interested in photography. In addition to the exhibition of apparatus and the picture competition, a very large number of entertainments are advertised.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A meeting of the Committee was held on Thursday, November 3rd, Mr. W. Bedford in the chair.—The Hon. Secretary stated that Mr. Frederick Hollyer had generously offered to devote the proceeds of the last day of his exhibition at the Dudley Gallery, Piccadilly, to the funds of the Benevolent. Since the last meeting the Secretary had received applications from many assistants wanting situations, and in three cases had been able to secure satisfactory positions, but there were still many applicants for work on the books. Messrs. Redmond Barrett (London), A. G. Tagliaferro (London), and H. Thompson (Sunderland) were elected members of the Association, and the Secretary stated that in addition to subscriptions from these gentlemen, subscriptions, donations, or other moneys had been received from Messrs. Jonathan Fallowfield, Oscar Scholzig, W. F. Rogers, the Eastman Company, Limited, T. Charters White, W. Fenton Jones, Wratten & Wainwright, and A. M. Levy. Four applications for relief were considered and dealt with as follows:—1. An applicant who had just secured a situation through the medium of the Association had only applied for a loan at the suggestion of the Secretary. The Committee granted a small loan to cover immediate expense, and to be repaid out of salary. 2. Application for loan of 2*l*., to enable applicant to clear a small pressing claim, and to redeem the apparatus required for work which was offered to him. Loan granted. 3. Application for loan of 5*l*., under circumstances similar to above. Loan granted. 4. Application for assistance to commence business. The Committee considered the application, and as the applicant was at present in a situation and not in indigent circumstances, it was decided that the case was not one to be dealt with by the Benevolent. In the cases where assistance was granted, very careful investigation had been made, and two of the applicants were personally interviewed by the Committee.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

J. BILLCLIFF.—Thanks for the information.

CREDIT.—Take out a summons in the local county court.

THOMAS EVANS.—We shall probably have an article on the subject.

COLLODIO.—We are unable to supplement the information you have obtained.

A. DONALD.—Possibly the two systems are dissimilar. Can you give us particulars of yours?

HERBERT JOHNSTONE.—An east top and side light will answer, provided you have suitable blinds.

T. MORRIS.—Try some of the coal-tar colours, say Judson's dyes, of the tint you wish to stain the wood.

N. COURTNAY.—We have had no opportunity of comparing the lenses named, hence we can offer no opinion.

GOLD.—Protosulphate of iron is a precipitant of the gold. You had better decant the solution containing the iron, and not boil it.

E. J. AUSTIN asks "if wooden dishes will answer for developing bromide prints, or if glass-bottom dishes are better? I find porcelain dishes too heavy for 24 × 18."—Either will answer quite well.

G. FINDLAY.—We do not recommend special patent agents. If you choose, you can prepare the specification yourself by applying at your post-office for the requisite forms, which will be provided free of cost.

C. B.—There will be an article on the subject in the next ALMANAC. We should advise you to write to one or two firms commercially engaged in zinc etching. We do not know any teacher we could recommend.

J. L.—If the emulsion fogs, the best way is to discard it and prepare fresh. It is not worth the trouble to attempt to restore small quantities of spoilt emulsion, more particularly as the attempt usually ends in failure.

A. B. C.—Wet-collodion slides, if the bath and collodion are in good condition, rarely require toning. However, flowing them over with a solution of one or two grains of chloride of gold in an ounce of water will, in some cases, be an improvement.

W. JONES writes: "I want to cover the glass of my studio with waxed paper to soften the light. Could you please tell me where I can get the paper?"—You had better prepare the paper yourself, by applying, with a soft brush, a solution of wax in spirits of turpentine.

J. L. W.—The mere fact of putting wheels on the studio will not exempt it from the Building Act. Such an idea exists, we believe, but it is a fallacy nevertheless. If you act upon the idea in defiance of the District Surveyor, you will place yourself in an unpleasant position.

INTENSITY.—The distance of the two subjects apart has nothing whatever to do with their coalescence in the stereoscope. The only difference will be that there will be a greater amount of relief in the one in which the lenses of the camera are separated to three or four inches than when they are closer together.

D. MALONEY.—Your failure is not to be wondered at. The temperature given was according to the Centigrade scale, and you tried working to the scale of Fahrenheit. Forty-five degrees on the former scale corresponds to 113° on the latter. No wonder you failed to make a highly sensitive emulsion. In French works the Centigrade scale is the one universally quoted.

OPERATOR.—The work is fairly good, but is much marred by the retouching. However, it is not up to the standard, either from a technical or an artistic point of view, of high-class London work. If you could obtain an engagement in a first-class house as assistant, you would there have the opportunity of improving yourself. That is the best suggestion we can make.

C C. C.—The want of sharpness is caused by the camera being moved during the exposure, notwithstanding your assertion to the contrary. The image, even the brick wall, is doubled throughout. Had the plate dropped in the rabbet of the slide as sometimes happens with thin plates and a weak spring on the partition of the dark slide, the doubling would have been vertically instead of laterally.

STEPHEN HARRIS.—The unequal toning in the prints is caused by the surface of the paper being contaminated with finger marks. The markings of the skin on the albumen are very palpable. The trouble is easily avoided with more care in the working. We are assuming that the paper was all right when you received it, but it is sometimes very carelessly handled by inexperienced packers.

M. HURST.—The engravings named would make excellent lantern slides, and they would be very popular, no doubt; but it should be borne in mind they are copyright, and it is piracy to copy them in any form. The proprietors of the copyright, we feel sure, would take proceedings against any one infringing their rights. This is scarcely to be wondered at when the high price paid for the copyright is considered.

S. C. R.—Photographic paper, suitable for ordinary silver (albumen) printing, is not made in the United Kingdom. The only reason to be assigned for it is that British paper-makers have not enterprise enough to take the matter in hand. Those we have spoken to on the subject say the consumption is "too small" (?) to make it worth while to experiment, and then lay down the requisite plant for its manufacture.

J. S. DAWSON says: "In your article on 'Has Albumen received its Death Blow?" on p. 708, in the instructions for mounting you omit to say how the prints are pressed in contact with the mounts. I usually use blotting-paper in silver printing; it does not answer with gelatine. This item is usually omitted in instructions for this paper, which I think is its greatest drawback."—We should be glad to receive the experiences of others on this point.

STUDIO.—We have not the book to which you refer, so cannot say if the studio there recommended is the best or not, and for the same reason we are unable to advise you as to the quantity of glass that is necessary for the top and side light. If you send us a sketch of the design, and the aspect in which you propose to build, we shall be pleased to advise you. Your proposed proportions, thirty feet by fourteen feet, are very good indeed for all-round work.

T. OWEN says: "An artist has just finished a picture, and has allowed me to photograph and sell copies of it. At the time I made my negatives copyright, and now I hear that another photographer is applying for permission to copy the painting, and is not unlikely to obtain it. Can I, if he does, prevent him from publishing his photographs because mine are made copyright?"—Certainly not, unless you hold the copyright in the painting itself. Your copyright extends no further than your photographs. The owner of the copyright of the painting can give permission to as many as he likes to make photographic or other reproductions of it.

D. MCANDREW says: "I am terribly troubled with spots on my prints; they can be seen when the paper is dried after sensitising if it be closely examined, and they appear larger after printing and toning. The spots always, of course, come in the most conspicuous parts of the picture. What can I do?"—If the spots appear directly the paper is sensitised, the fault lies with the paper. It is a pity to waste time in printing paper that has spots upon it, unless care is taken that where a spot exists the paper is so placed on the negative that the defect comes on some unimportant part. As we have already intimated, such paper should be discarded.

PACO asks: "1. Which is the best size of condenser for an optical lantern? 2 Is there in practice any actual loss of light when using a four-and-a-half-inch condenser, as compared to a four-inch one? 3. Does the diameter of the condenser bear any relation to the focus of the objective? In other words, will a four-inch condenser illuminate a slide (with cushion square mask) equally as well and as evenly with a five, six, or ten-inch objective? 4. What percentage of increase will there be in the light on the screen when using a triple condenser (two plano-convex lenses plus a small meniscus) as compared to an ordinary plano-convex condenser?"—1. Not under four inches, but four and a half inches by preference. 2. Not if the slide be placed properly in the cone. 3. The back lens of the object glass must be so situated as to embrace all the light projected by the condenser. 4. It would be difficult to determine.

J. R. G. says: "1. I want to know when a good pyroxiline could be obtained which would give good density in collodio-bromide emulsion? I have tried Hopkins & Williams', Thomas's, and Rouch's. The last-named I purchased, and dissolved 1 ounce in 20 ounces of ether (717 sp. gr.) and methylated alcohol, (the old methylated), Hopkins & Williams, and, after well shaking up, a dense deposit was thrown or settled down about two inches thick at the bottom of a forty-ounce bottle; nor would any more of it dissolve. I have made three batches of emulsion from it, but I cannot obtain density; it works beautifully clean otherwise. My experience has been the same with the other two makes, viz., a beautiful creamy emulsion which worked very clean, *but no density*. 2. Double bromides. The ammonium bromide and cadmium bromide I obtained from Hopkins & Williams, and used 98 grains of the former and 172 grains of the latter, making it exactly according to Mr. W. B. Bolton's method; but, when I add it to the collodion, I cannot get all of it to dissolve, no matter how much I shake it. A fine white crystallised deposit falls to the bottom of the bottle, which seems to me to be part of the bromides undissolved, and to filter it out would leave it uncertain as to the amount of soluble haloid in the emulsion. I may say that I have made several lots of emulsion with zinc bromide, and can get any amount of density with this salt; but I find it very liable to cause small transparent spots in the films, although I dissolve the zinc bromide in pure alcohol, and have let it settle for months before using. I always wash the emulsion with pure distilled water, and dry on a hot-water bath, and am considered a very careful worker. I use up to 22 grains per ounce of silver nitrate in emulsifying, and have used as low as 15 grains per ounce, but it does not seem to make much difference in the density. The colour of the emulsion when made is a deep ruby orange. I should like to be able to make an emulsion which would give good density and warm tones without having to intensify."—Working under such conditions as our correspondent describes, successful results should be obtained. Perhaps, however, some of our readers who have experience of collodion emulsion can be of assistance in the matter.

AN ACROSTIC.

D'YE want to make a photographic work of art?
A thing of beauty and a joy for ever?
Very easy is the photographing part;
Indeed, one need not be the least bit clever.
See that the image is a shapeless splodge
On screen. Expose, the fraction of a minute.
N.B.—Your work of art is made. The dodge
Is artful, but there is no nature in it.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1698. Vol. XXXIX.—NOVEMBER 18, 1892.

A NEGLECTED PROPERTY OF GELATINO-BROMIDE OF SILVER.

At the meeting of the Photographic Society of Great Britain, last week, in the remarks on Mr. Howard Farmer's paper, entitled "Some Remarkable Properties of Silver and Gelatine," the President, Captain Abney, said that if the gelatine film were more experimented with there were many possibilities that would open out in photographic printing. This no one can deny, when it is considered how closely a gelatino-bromide of silver film is, in its properties, allied to one of bichromated gelatine, when modified by the action of light. In the beginning of this year we devoted an article to the subject in which this similarity was pointed out. We again refer to the matter, as there is no question that films possessing the properties of those of bichromated gelatine, with the sensitiveness of an ordinary dry plate, have immense advantages from a commercial point of view, more especially at a season like that now upon us. In working the photo-mechanical processes, such for example as collotype, Woodburytype, and other processes based upon gelatine in conjunction with bichromates, much inconvenience and loss are experienced during the winter months by the lengthened exposure necessary.

In his paper, Mr. Farmer says, that a silver bromide plate developed with ferrous oxalate, and then placed in a solution of ammonium bichromate, behaves, when treated with cold or hot water, in the same way as exposed bichromated films — as carbon prints in fact. There is no necessity, however, to treat the silver image with the bichromate at all if it be developed with pyrogallic acid, and this fact was established many years ago. The property was first noticed, we believe, by Mr. J. W. Swan, who found that a developed bromide film was in many respects analogous to an exposed film of bichromated gelatine. It absorbs water and swells up in proportion as it has been protected by the negative from the light's action, just as does the film of a collotype plate, or one prepared for the "swelled gelatine process." It was also noticed that, as in the processes just alluded to, the swelling is augmented by the application of a slight heat. Recognising the commercial application of this property, he in 1879 took out a patent for producing printing plates based upon it. The process is this :—

A negative is taken on a dry plate in the camera in the ordinary way, and if a half-tone typographic block is wanted the exposure is made with the usual line screens. After the image is developed the plate is placed in tepid water, or, while still moist, subjected to slight heat. Under this treatment the film behaves like one of gelatine sensitised with a bichromate. The image swells up and acquires sufficient relief to admit of a satisfactory printing block being obtained. Mr. Swan in his specification also mentions another method of making reliefs, based upon the similarity of the bromide to the bichromated film—namely, by dissolving away the gelatine with acetic acid. He also refers to the effect of different substances in modifying the grain of the bromide image, which produce similar results with the bichromated one.

In 1881 Mr. Warnerke recognised a further analogy between the exposed bromide film and one of bichromated gelatine. This formed the subject of another patent. The bromide emulsion in this case is spread upon paper, and after exposure is developed with pyrogallic acid. It may then be fixed or not with hyposulphite of soda, as it makes little or no difference in the end. After drying, the picture is treated exactly as if it were an exposed carbon print. It is placed in cold water and squeegeed on to a glass plate or other support, allowed to rest for several minutes, and then put into warm water. The original paper support now comes off, and the gelatine, unaffected by light, dissolved away, leaving the image in relief, just as in the case of the carbon print. Indeed, Mr. Warnerke proposed to add pigments to the silver emulsion, and thus secure a carbon tissue having all the sensitiveness of gelatine plates.

Mr. Warnerke, in a paper read before the Photographic Society of Great Britain (see page 268 of our volume for 1881), recognises the value of this method in producing Woodbury reliefs, and he mentions that for this purpose the emulsion must be in a thicker layer and be less opaque, so that the light may penetrate deeper into the film, and thus give a high relief. Now, these conditions are precisely analogous to those existing between ordinary carbon tissue and the usual Woodbury film. The latter is simply a thicker film of gelatine, and contains less pigment ; hence the light in printing enters deeper into the film, and thus renders a greater thickness of the gelatine insoluble. Mr. Warnerke also refers to other applications of this, at that time novel, property of gelatino-bromide of silver in connexion with other mechanical processes.

Reference was made the other night to the use of silver salts in the collotype process. Some twenty years ago it was customary to add a very small proportion of iodide and bromide of silver, as well as chloride of gold, and several other substances, to the gelatine, though no one seemed to know why. One by one the employment of these things was abandoned, and now only gelatine is used. It may, however, be mentioned in connexion with this point that the use of silver salts, as employed at the time referred to, bears no relation whatever to the property now under consideration. They were used only in infinitesimal quantities, and took no part at all in modifying the gelatine.

As we have said before, this neglected property of gelatino-bromide of silver may be turned to great advantage commercially. It would be superfluous for us to extol the value of collotype plates, Woodburytype, and other films for mechanical work, which would have the sensitiveness of dry plates where rapidity of production is a consideration and the light is bad. We may probably recur to this subject when Mr. Farmer's paper is published in full.

METHODS OF ARTIFICIAL ILLUMINATION FOR ENLARGING OR REDUCING.

We may supplement our article of last week by a brief account of the simplest way of utilising the reflector therein described. Starting with the built-up shell of cardboard, we have to decide upon the best means of introducing the apparatus by which the light is produced. This will depend in great measure upon whether the magnesium is to be used in the form of wire or powder, though we may say at once that the reflector is far better suited for the former than the latter; indeed, from the point of view of convenience, when using the powder a "reflector" of much larger dimensions and simpler construction, an ordinary square box, in fact, will suffice for all purposes of reproduction.

Assuming, then, that wire, or rather ribbon, is to be used, we have to provide means by which the supply of magnesium is fed into the reflector, so as to become ignited at a spirit or other flame placed at or near its focus. In the magnesium lamps of commerce, several of which have been before the public for many years, clockwork is utilised for the purpose of regulating the supply of magnesium; but, though this arrangement is perfect in action, it is necessarily expensive, while for our purpose no great nicety is necessary, and the object is to adhere to the most simple means. A little hand lamp, placed on the market some three or four years ago at a cost of two or three shillings, will supply the principle upon which we have to work; indeed, if these lamps are still obtainable, it will save trouble if one of them be adapted to the reflector almost without modification.

The essential parts of the lamp consist of a spindle, upon which the coil or roll of ribbon is carried, and from which it passes between two little rollers covered with indiarubber tubing, and pressing tightly together, into a thin bent tube, which conducts it to the igniting flame. One of the rubber-covered rollers is provided with a winch handle, in rotating which the ribbon is drawn off the store coil and passed on towards the flame, and it requires very little skill to keep up a tolerably regular speed, and, consequently, a uniform illumination.

In a portable lamp, such as the one we have alluded to, the igniting flame is almost necessarily a spirit flame, since it would be manifestly inconvenient to be constantly attaching and detaching an indiarubber tube to connect it with the gas supply, even where such might be available. Even in the case of a fixed apparatus, as our reflector might be made, there are many arguments in favour of spirit; but, as in the majority of instances in which it is used it will not be in a fixed position, we may safely decide to rely upon spirit.

Before commencing on the actual arrangements, the reflector should be first attached by its back portion to a solid block of wood roughly hollowed to fit its external shape, glue or screws, or both, being used for the purpose. This will form a solid basis for fixing the various attachments, and will also enable the reflector itself to be more firmly held upon any suitable support. The most convenient support we have found is an upright iron rod with heavy foot, such as is used for retort stands and similar purposes, upon which the reflector may be made to move in precisely the same manner.

Proceeding to the fixture of the lighting arrangement, we will take the spirit flame first. The easiest way of managing this is to insert firmly into the wood block, from the inside, a piece of stout wire bent into a circular loop at one end like a retort ring, the position of the loop when fixed being a short distance below the calculated focus of the reflector. This will serve to hold a plug of cotton, or asbestos, or a disc of felt, to be saturated with spirit, or, better still, a small metal capsule into which spirit may be poured. The filling of the capsule and the ignition of the spirit may be effected by means of one or other of the ventilating apertures in the upper and under sides of the reflector; or a special opening may be made at the side, which will also answer, when covered with a movable coloured glass screen, for watching and regulating the supply of ribbon when the apparatus is in use. Of course these apertures should be as few and as small as possible, in order not to interfere any more than needful with the regularity of the illumination.

For the introduction of the ribbon, a thin tube wide enough to let it pass easily and smoothly must be passed right through the wood block to a point within the reflector, so far above or behind its focus that when ignition takes place it is exactly at the focal point. The exact point may not be arrived at at once, but if the tube be made to slide stiffly in the wood block, and a similar slight movement be possible with the spirit holder, then the arrangement will be capable of any adjustment that may prove necessary. The fine tubing necessary for this purpose may be obtained at any of the model shops, or at many of the dealers in clockmakers' materials in Clerkenwell. If obtained of a size a little less in diameter than the width of the ribbon and then slightly flattened, it will be better than if used round.

The details of fixing the feeding rollers need scarcely be entered into here as they will suggest themselves to the individual mechanic, but if any trouble presents itself the better plan will be to procure one of the "lamps" we have spoken of, and to thrust its tube into the desired position. A side aperture mentioned above, if placed opposite the igniting point, will enable the operator to watch exactly how much ribbon he is winding off while it is burning.

A couple of tubes of brass or tin pushed into the ventilating holes will improve the working of the apparatus by inducing a more vigorous current to carry off the magnesium fumes. The lower one need not be more than two or three inches long, but the upper or chimney may with advantage be a foot or more in length, so that it does not render the affair top heavy. They do not require careful fixing, but may be arranged to push in and out of position when required for use. As short a portion as possible of each should protrude into the interior.

Two or three coats of white paint—preferably "flatted"—for the interior, and a sheet of ground glass for the front will complete the apparatus, which will then form a very efficient radiant for the purposes intended.

A New Photographic Institution.—We are informed that steps are being taken to discuss the advisability of forming in London a central photographic club, to which professional and amateur photographers, the trade, and, indeed, all sections of photo-

graphers would be eligible for election. The club would be open during recognised club hours, and many facilities not enjoyed by existing institutions—which it is intended rather to supplement than to rival—would be afforded. The idea is receiving influential support.

A New Comet.—Photographers with astronomical predilections will be interested to learn that a new comet has made its appearance. It is to be found in the constellation Andromeda. Mr. Edwin Holmes, who first noted it, writes that, although the night was hazy, he was able to distinguish it with an opera glass.

Rapidity of Plates.—It is only a year or two since it appeared that the desire for plates of phenomenal rapidity was abating: but to judge by recent indications, there has been a revival of feeling in their favour, the makers vying with each other in producing sensitive films which are alleged to possess higher rapidity than that hitherto attained. Whether the most rapid plates of the present day are, after all, really quicker in practice than those of five or six years back is a theme for speculation. One thing remains certain, and that is that, except in comparatively few branches, photographic plates of extreme rapidity are not desiderata.

Cost of Electricity.—The latest authoritative statement as to the actual cost of electricity was made at the recent session of the Junior Engineering Society. The cost, to what may be termed the makers, will be not much less than eleven pounds per annum for every kilowatt, and afterwards to give the supply will not cost much less than one-third of a penny per unit. It is hopeless, it is said, for electricity to compete with gas in this country all along the line, if price is the only consideration; but, with selected customers, electricity is cheaper than gas.

Photography by Special Wire.—There seems to be a determined effort to assert, or to prove by realisation, the possibility of sending, by the medium of the electric telegraph, actual views and portraits. What is now asserted is, that a syndicate is proposed in Chicago which will undertake to send photographs by telegraph, and reproduce them on the screen in distant cities by means of a system of tele-photography. The exact system is said to have been described in the *Figaro* some three years ago, in connexion with experiments by M. H. Courtonne, a French chemist. Possibly the method may have something in common with that of Amstutz which we briefly described in the early part of the year.

Microscopic Cover Glasses and their Dimming.—Herr R. Weber has been investigating the cause of the clouding that occurs on the inner surface of the thin microscopic covering glass which would render them entirely useless for photography. He finds it due to the composition of the glass. Those glasses which contain an excessive amount of alkali soon lose their lustre and become dim when exposed to moisture. Passing by as not necessary for our readers an account of the analyses he made of various glasses, we may give his practical conclusions, which should be well borne in mind by those who practise photomicrography. He finds the glass most stable in air is that which is slightly green in colour; hence the pure white glass, so much affected by some mounters, should be entirely eschewed when their use in photography is in view.

Remarkable Radiations.—The old idea of resolving light into three constituents, "actinic, calorific, and luminous," has long been exploded, and radiations only are spoken of, the various effects named being functions not of a particular radiation but of what might be termed the translating medium—that is, the medium which renders them sensible to our human faculties. M. Piclet, famous for his success in condensing the "permanent gases," has found that the radiations from bodies of extreme coldness possess a power of penetration almost passing belief. Hitherto the surrounding a body with a wall of cotton wool has been considered sufficient to protect it from all radiations, ingress or egress; but M. Piclet finds that when the temperature is reduced to, say, 110°, the long ether waves will pass readily through almost all bodies, a thickness of over half a yard of cotton-wool being no protection to bodies at that temperature. When they are exposed to a lower temperature they cool with equal rapidity "whether the layer of wool be two, ten, or fifty centimetres thick, i.e., an inch, four inches, or over half a yard."

DENSITY IN COLLODION EMULSION PLATES.

The troubles alluded to by your correspondent "J. R. G." in last week's JOURNAL in connexion with the want of density in collodion emulsions are perhaps not new or confined to his own practice, for the difficulty of obtaining sufficient vigour combined with sensitiveness has been known since the earliest days of emulsion photography. Still I am inclined to think that the trouble is greater at the present day than it was ten or twelve years ago or when collodion emulsions were more in vogue for landscape and general work.

The fault is due undoubtedly to the fact, that nowadays it is next to impossible to obtain pyroxyline of exactly the right kind for washed emulsion of the most rapid type, though it is comparatively easy to satisfy the requirements of the slower forms of emulsion, especially unwashed. So limited is now the demand for pyroxyline of that particular kind, that it is not worth the while of any of the manufacturers to make a special article of it, particularly as it is the most difficult of any sort to produce of uniform quality. Whereas in former days every dealer of repute kept in stock "high-temperature" cotton specially adapted for emulsion work, I question whether there is, to-day, more than one place in London where it can be obtained.

Of the the three samples mentioned by your correspondent, I only know the first and last, both of which in my hands work well, though the latter is the one more suited to washed emulsion work. The sediment complained of is no detriment to the working of the pyroxyline, but rather a necessity of its manufacture, for it is very rarely that a really "high-temperature" cotton, or one that gives a "powdery" and organic film, will dissolve completely in ether and alcohol. In the old days it used to be considered almost a *sine quâ non*, even for wet collodion, that the cotton should leave some sediment, and some of the more powdery kinds that gave the best results when used dry were remarkable for the quantity that remained undissolved. At the same time it is by no means an unusual occurrence to find a sample that gives a perfectly clear collodion that will also answer for emulsion work.

The want of density complained of is most likely traceable to one, or perhaps both, of two causes in your correspondent's case, namely, using the collodion too soon after bromising and washing the emulsion before it has thoroughly set. There is one other cause that may work with many samples of pyroxyline, though not with others, namely, the presence of excess of bromide during the whole period of sensitising.

With regard to the first cause, though it is by no means impossible to get any required density with an emulsion that has been sensitised immediately after bromising, as is frequently the more convenient plan, still it is beyond doubt that density comes far more readily, under ordinary treatment, when the collodion has been allowed to "ripen" for at least a few weeks after the bromides have been dissolved. This is more especially the case when bromide of cadmium is employed, either alone or in combination with another salt; if ammonium or zinc bromide, alone or in conjunction, be used, to the entire exclusion of cadmium, the collodion may be used a very short time after bromising without any apparent loss of the power of getting density. But for several reasons I have never greatly liked the zinc salt, and greatly prefer the double salt of ammonium and cadmium to all others. I should prefer ammonium alone were it not for its low degree of solubility in alcohol, and the necessity it involves of adding more water to the collodion if an emulsion rich in silver is required.

The loss of density arising from washing the emulsion before it has properly set occurs with every kind of bromising salt, but it is less likely to happen, other things being equal, with cadmium than in other cases, owing to the peculiar action of that salt in increasing the viscidity or "body" of the collodion. Bromide of ammonium tends

to produce a precisely opposite result, rendering the collodion thinner and more fluent, while the zinc salt seems to set up a sort of process of disintegration, which brings about a still greater fluidity, and thus reduces to a still greater extent the resistent power of the emulsion in washing. In any case the tendency of the washing process is so greatly in the direction of removing valuable density-giving constituents of the emulsion, especially when any considerable proportion of the solvents is left behind, that it is always desirable to let it get as dry as possible before commencing to wash.

Although I am strongly averse to washing the emulsion when it contains free silver, except under very special conditions, I fully recognise the advantage that accrues from the action of free silver during at least a portion of the period of emulsification. In the first place, with most samples of pyroxyline it greatly expedites the formation of a rich and "creamy" emulsion, and this is particularly the case with one of the samples mentioned by "J. R. G."—Rouch's. In the presence of excess of bromide, no matter how heavily silvered the emulsion may be, a beautifully fine but almost transparent film is produced, and this state of affairs will continue after a very long period of "ripening." The density given by such an emulsion under ordinary development is out of all proportion to the *appearance* of the film, but at the same time it is far inferior to that obtained when free silver has been allowed to act for ever so short a period.

If, in sensitising, a portion of the collodion be kept back, say, one-fourth, and the remainder sensitised with the full quantity of silver, the latter will be considerably in excess, and the result will be that in an hour or so a rich dense film will be given that differs entirely in appearance from that produced with excess of bromide after a week's keeping. The remainder of the bromised collodion may then be added without destroying the physical good qualities of the emulsion, but, what is of greater importance, the film will be much more sensitive, and will develop to any density without the slightest trouble.

In advising your correspondent how to get out of his difficulties, I would therefore suggest, first of all, that he should prepare a stock of bromised collodion, and allow it to ripen before use. In doing this there need not be the least uncertainty or ambiguity as to the precise proportion of bromide present in a given bulk after filtration or clearing. If a certain quantity of bromide be dissolved in a known volume of collodion, it matters nothing how much of that volume remains at the bottom of the bottle as sediment; the remaining clear portions contain exactly the same proportion of salt as the whole bulk, and may be measured off for use as required.

Next, I would say, in washing the emulsion, eschew all "fancy" methods of precipitation and suchlike, and follow the good old-fashioned plan of thorough evaporation, using heat if necessary—of course after the emulsion has well "set"—to thoroughly dry it. There need be no fear of the salts not washing out, for, as a matter of fact, they come out more easily from the *dry* "pellicle" than from that which is saturated with dilute spirit, the effect of which is to resist or prevent the penetration of the washing water. From the dry emulsion the soluble salts dissolve almost at once, leaving it not only quite as free from soluble matter but in a better condition to dry quickly before redissolving.

Thirdly, I strongly recommend the method of allowing for an hour or so the action of free silver by sensitising, as I have mentioned, a portion of the collodion with the whole of the silver, and afterwards adding the rest of the collodion. Even if time be an object, it will be gained by this method, for the simple reason that, though the remainder of the collodion be added immediately after sensitising, a better result will be gained, both as regards sensitiveness and density, than with two or three days' ripening in the presence of excess of bromide. But it is absolutely necessary to remove the excess of silver before washing.

With regard to the second difficulty mentioned by your correspondent, the partial insolubility of the double salt of cadmium and ammonium, I can only say it is quite contrary to my experience, and I have used it for a great many years now. Mixed in the proportions named of the two constituents, the compound dissolves easily to almost any extent in ordinary methylated spirit. I always dissolve it in spirit before adding it to the collodion, and, judging from its ready solubility in that menstruum, I should think there is quite margin enough to permit of any reasonable quantity being dissolved in the collodion itself. I have so used it frequently, and have never experienced the difficulty mentioned. I can scarcely see how the result could be produced by improper treatment in the preparation of the double salt, for, if excessive heat were employed in fusing it, the first result would be to volatilise a portion of the bromide of ammonium, and, by thus increasing the proportion of the cadmium salt, render the compound *more* soluble. At any rate, I can only suggest dissolving in alcohol first.

I hope shortly to give an account of some experiments carried out some months ago, but stopped by illness, which had for their object, first, the production of density, regardless of the quality of the pyroxyline; and, secondly, the restoration of density—or the power of rendering it—to emulsions from which it has been removed by improper washing. So far as the first part of the task is concerned, I may say I think I have achieved what I sought; and, as to the second, have obtained most promising results, so far.

W. B. Bolton.

ON THINGS IN GENERAL.

While "Free Lance" has been rusticating, the victim of some of the ills that flesh is heir to, there has been some fine tilting by other doughty champions. I have been attracted by the friendly passage of arms between Messrs. Cadett and Haddon, and all for the good of photography. We all know the tendency of photographers to work by rule of thumb, and to leave exactitude of statement to professors and others, a tendency much to be deprecated. I believe I have done my share in expelling the "pinch of pyro" style of formula from the pages of photographic literature, and it may be fairly hoped that accuracy of statement may continuously increase in the communication of all practical or theoretical contributors to the store of knowledge. Hence I am with Mr. Haddon in his desire to see the behaviour of solutions of ammonia properly understood. But why have the disputants been content to refer to authorities who once held the field, but whose results have been fairly supplemented by recent and still more exact workers? The subject of the strengths of ammonia solutions of various specific gravities is important, and has been well worked out by modern investigators. Still, there is by no means uniformity of result in the data they set before us. Thus, taking the table by Carius in the new *Watt's Dictionary*, we find, for example, that when the solution is of specific gravity ·9001 its ammonia percentage is 29·0 (at 14° C.), and at ·9498, 12·6 per cent. The results of G. Lunge and T. Wiernik at 15° C. (see *Zeit. Ang. Chem.*, 1889, 181–183) give, at ·950, 12·74, and at ·9, 28·33 per cent. At ·884 and 8844 respectively, we have 34·10 and 36 per cent. But, leaving discrepancies aside, a little calculation will show any one that, according to either of these tables, if we mix equal weights of strong ammonia, say, 884, and water, the calculated result will show an error of over three per cent. when compared with the indications of the table. The slight difference in the temperatures may be ignored, seeing that for a plus or minus difference of one degree the correction is only about ·0006.

I have, on a previous occasion, drawn attention to what may fairly be considered a scandal in regard to the sale of chemicals, chloride of gold being advertised for sale at a price not very much over one-half of the value of the metallic gold it would contain if the old style of salt were sold. As a matter of fact, chloride of this stamp contains only just as much gold as the conscience of the dealer permits. The above statement gives a mild idea of the elasticity of that function in some dealers. I am, however, pleased to see the advertisement of a well-known dealer, who now states that he will sell none but the product of a maker whose name is above suspicion, and who guarantees that his fifteen-grain tubes shall hold seven grains of metallic gold. Any one who sells any other sort deserves hooting out of the trade.

I see some correspondent has amusingly been inquiring where a particular sort of medium, "Opie's," can be obtained. One would have thought that every one had heard the old story of that eminent painter who, when asked what medium he mixed his colours with to make them so brilliant, replied, "Brains, sir." But the P. D. has been at work with the Editor's reply, and converted what no doubt

in his "copy" was "vulgar tongue" into "vulgate." He would have to look a long way into that book before coming across the word "brains!"

Another correspondent, W. Potter, asks for information on the anastatic process of printing. There is no doubt that with old works the utmost difficulty will be experienced in getting the ink to set off; but I may suggest to him to try the effect of submitting the old print for some time previously to the vapour of benzol or chloroform, or, perhaps, if long continued, to that of turpentine.

What a neatly arranged hoax that seems to have been—the discovery of Noah's Ark by Archdeacon Norris. Mr. F. R. A. S. has treated it capitally. We may, however, even yet be treated to a continuation of it, and see snap-shots sold at a shilling a copy. I doubt though if the lynch-pins of Pharaoh's chariots would meet with approval.

I am interested in all accounts of new developers, but when Mr. Pike tells us how an amidol-developed plate gave less halation than a similarly exposed one treated with "pyro," I must say that, though feeling bound to accept that gentleman's *bona fides*, one cannot but feel that he has made an error somewhere. I should be very glad to be persuaded into a belief that one developer will give less halation than another, but at present I feel a verdict of "not proven" must be given.

The Editor is to be congratulated on his new *Lantern Supplement*. It will "supply a long-felt want," and, as a matter of course, have a crowd of imitators. A sharp look-out will have to be kept on doubtful suggestions from correspondents, such, for example, as that compressed oxygen deteriorates with keeping, its final state being nothing but atmospheric air, though there was plenty of pressure. This, of course, is an impossibility altogether. Not so, however, Mr. Barker's valuable caution that compressed hydrogen should be tested. When ordinary coal gas is compressed it is quite to be expected that there will be deterioration, some of the less volatile hydrocarbons are sure to be deposited. There are times when it is difficult enough to keep the gas from depositing in the ordinary main supply pipe of premises where it is used under ordinary conditions, far more likely then is it that when compression takes place a deposit should form, and, again, a further deposit when the inevitable cooling takes place during the use of the cylinder for an exhibition. These factors are not sufficiently borne in mind, and it is by no means difficult to see that an accident might be brought about by particles of deposit under some untoward conjuncture of circumstances.

FREE LANCE.

THE PLAGUE OF MEDALS.

In view of the appalling deluge of gold, silver, and bronze raining upon the photographic world in the shape of medals, which in too many cases represent premiums of considerably less intrinsic value than the cost of the material from which they are made, a few remarks upon the present want of system in bestowing "metallic honour" upon candidates for fame are not uncalled for.

The practically unlimited multiplication of worthless, or comparatively worthless, tokens, is not only undesirable in itself, but is, moreover, a very grave injustice to those who have in past times nobly earned their rewards by work well done; for it is in most quarters admitted that in our degenerate days to be merely the winner of a medal, is to receive no more distinction than is a peerage in that all honoured community sung of by W. S. Gilbert, where "Dukes were three a penny."

The question is, How shall we restore to this should be precious emblem of success its pristine value? No doubt there are more ways than one in which this may be effected. In the present communication I do not intend to try and exhaust the alternatives; let me however, in passing, say that it would be well if at its next gathering the Photographic Convention should, putting on one side some of the highly diluted topics in which it seems to find a calm delight, bring this question to the forefront, and seek by some authoritative *pronunciamento* to stay the cruel kindness of those who are in truth burying photography beneath a heap of metal discs.

Let there be no mistake, I am not protesting against tangible rewards. I can even bear with that somewhat maligned individual, the pot hunter; for, if one man can by superior ability sweep the board, why should he not do so, providing, of course, that this be not effected by means of a plucky production, but by sustained and repeated excellence? All I urge is that a medal shall be an honest certificate that the winner has done something notably praiseworthy.

The first step to take in bringing about the much-needed reform is, I venture to think, to consider whether any improvements are possible in the system of awarding medals adopted by the Parent Society. Clearly it is a case with the aforesaid of *noblesse oblige*; and, besides, the value of example is considerable. As an individual who belongs neither to the above nor to the Charing Cross-road Club, I may perhaps be credited with approaching this somewhat delicate phase of the subject without possessing any undue bias; if I have any predilection at all it is in favour of renovating, rather than wrecking, an institution which can point to such a useful and distinguished past as can the Photographic Society of Great Britain. Although, as above explained, I am to some extent "out on the terrace," yet, as the working president of an unusually active provincial society, and also in other capacities which need not be particularised, a considerable volume of genuine and uncoloured opinion has come to my ears regarding the Pall Mall medals, which for reasons that are both good and politic do not see light in the press; none the less these *voces populi*, because they are free as air, are when found to be in substantial accord deserving of more than passing attention. Without of necessity endorsing the opinions I have found to prevail, I give them below for what they are considered worth. They come under three main heads:—

1. Too many medals.
2. Medals given for poor work.
3. Favouritism.

Respecting the first point, there certainly seems an absolute consensus, to which I also subscribe, that the Judges have woefully "cheapened Paradise." As to grumble the second, less unanimity prevails. Of course as long as there exists a critical faculty, and it does not seem to be dying out just yet, so long will there be found criticasters to impugn the decisions of those who have to give the palm.

Still, it would almost seem that an improvement on the present methods of judging is not impossible, of which perhaps more on a future occasion. Coming to that ill-flavoured suggestion of favouritism, personally I think there is but small foundation for any such accusation. It is of course inevitable that a given man will have greater sympathy for, keener appreciation of, some particular form of photographic expression than for another form which may perchance be at least equal, and, in some folk's estimation, vastly superior.

But to see pink where another sees blue is not to be guilty of conscious partiality; and, if a man prefer portraits seemingly taken in twilight, should we wax wrath at his admiring landscapes, which represent smiling nature as being in a perpetual condition of dismal dumps?

Of course, over and above individual predilections and aversions, there are such disturbing things as friendships, clubs, commercial considerations, and coteries as "rings," which, having as a rule their headquarters in London, are certainly not favourably thought of by provincials, nor by others who are without the pale.

Allowing, for the sake of argument, that such closed circles use their influences unworthily, it is to be remembered that the Photographic Society of Great Britain is in no wise responsible for their existence.

But the contention which has been put forward is, that knowing such "communities of interest" exist, the Parent Society should see that the present system of judging at the Pall Mall Exhibition is drastically remodelled.

Of course ardent reformers always shout for a complete upheaval rather than a revision, but to me and most others it would appear that, without on the one hand taking too seriously these mutterings, which though at present not particularly loud are decidedly deep, the executive might well, by the timely introduction of a few remedial regulations, greatly reduce the causes of dissatisfaction. Upon this point it will be my pleasure to submit some remarks in a future article, which, being prompted by a spirit of friendly advice, may possibly not be unhelpful to the powers that be.

HECTOR MACLEAN, F.G.S.

LEYTONSTONE CAMERA CLUB EXHIBITION.

THE first annual exhibition of this, one of the most vigorous of the younger photographic societies, was held on Thursday, Friday, and Saturday of last week, being opened on the first-named day by Lady Brooke in the presence of a large gathering. For the delectation of visitors, the Club put forward, in addition to the display of pictures, a varied programme of music, lectures on photographic topics, demonstra-

tions, lantern exhibitions, and other attractions. Variety, it has been said, is charming; but as one of the declared motives of the Club in holding the exhibition was to afford to neighbours and friends "entertainment blended with instruction," in the first half of which it appeared on the occasion of our visit to be succeeding admirably, the brevity, and maybe the inadequacy, of this notice will easily be understood from the notorious difficulty of criticising a collection of pictures in the presence of a numerous body of perambulatory visitors, the music of "the Veronese band," and other distractions.

Naturally, being a first attempt, the Club effectively established the fact that it has much to learn in arranging an exhibition of photographs. We were informed that the large hall, in which the pictures were displayed, was only available a few hours before the opening time, a circumstance which more than excuses an indifferent hanging, and may perhaps account for the scarcely successful manner in which the judges —the Rev. F. C. Lambert, and Messrs. A. Horsley Hinton and E. J. Wall—discharged their office. The exhibition contained many photographs of high artistic and executive skill, copiously diluted with a large number of commonplace, if praiseworthy, efforts. If the Club undertakes a second public exhibition, it may be well advised to eliminate such pictures as tend to depress the average of quality.

In Class A (landscape, seascape, and architecture; members), Mr. H. H. Summer's charming tree study, *Near Home*, rightly gained a bronze medal; and Mr. D. G. Riddick's highly commendable wave picture, *Where Grace Darling Won her Fame*, was a clever seascape full of motion. The class, on the whole, was a good one; better relatively, in fact, than B (portraits and figure study), in which, as might have been expected, merit was less conspicuous, a remark that also applies to Class C (enlargements). Here Mr. A. E. Bailey, with *When the Tide has Gone—Ilfracombe Harbour*, showed, probably, the best work, the picture being plucky, well exposed, and carefully printed. In Class D (lantern slides) we are inclined to think the last-named gentleman should have had a higher reward than "commended," his work being very crisp and artistic. In Class H (lantern slides—open) great excellence was displayed, Messrs. Hankin, Farmer, and Carpenter (flower studies) showing remarkably fine work, and, with Mr. T. E. Freshwater (photo-micrographs), securing awards.

Of the open classes, E (landscape, seascape, and architecture) was the most noticeable, Mr. W. Thomas, with his numerous small cattle and sheep and marine studies, again earning the high opinion we formed of his work at Pall Mall. Mr. Francis W. Grant's snap-shots were among the cleverest in the Exhibition. Mr. G. W. Ramsey's *Sunset* (highly commended), a minute but highly realistic study; Mr. C. H. Oakden's really fine series of interiors of Ely, Canterbury, and St. Saviour's, Southwark; Mr. C. Court Cole's Oxford interiors stood out prominently in this class. But, as regards *On the Marshes, Hackney*, by Mr. F. J. Clements, to which the Judges, in their wisdom, awarded a silver medal, we must confess that, despite its pleasing red tone and good selection, it struck us as having been well beaten several times over in its class.

Mrs. S. F. Clarke in Class F (portraits and figure studies) with *Aha*, two charming ladies descending the steps of a terrace, gained a bronze medal for a very delicate and refined picture. There was nothing superior to it in its class, which, however, was not a strong one. In Class G (enlargements, open) we liked the *technique* and the humour of "*Come here, you rascal!*" by Mr. J. H. Gear, which if we mistake not we saw at Pall Mall, and Mr. J. Carpenter's excellent study of *Corn Flowers*. Mr. A. Champion's "*Scene in my Garden*" was an excellent enlargement as one could judge from the small original which accompanied it. Among the pictures sent for exhibition there were many with which we and most of our readers are familiar.

In congratulating the Leytonstone Camera Club on its first exhibition we may bear testimony to the energy displayed by the executive, who deserved and we hope gained success. We shall watch future exhibitions of the club with interest. As a conclusion we may note that the catalogue was embellished with a capital collotype frontispiece of the old house on the site of which the exhibition hall stands, executed by a local firm, Messrs. Webber & Sons.

HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

This exhibition was opened on Tuesday afternoon last, November 15, by Sir Albert K. Rollit, M.P., who, in performing the ceremony, made a capital little speech, which, as a rapid survey of the principal aspects of modern photography, left little, if anything, to be desired even from a photographic as distinct from a popular point of view. It is not every member of the Legislature, or, indeed, any other distinguished person who opens a Photographic Exhibition, that can string half a dozen sentences together without exposing a lamentable knowledge of the subject, and, if Sir Albert only knows as much about politics as he appears to do of photography, then is his constituency and his country blessed.

Admirably hung and arranged, and comprising, in addition to a remarkably excellent display of work by the Society's own members, a selection of pictures from the principal photographers of the day, such as in quality we must own to have seen barely excelled either at Pall Mall, the Camera Club, or any recent exhibition, the Hackney Photographic Society's Exhibition may at once be pronounced an unmistakable success. The hall in which it was held is well adapted for the purpose, a by no means common occurrence with photographic exhibitions; and both in *ensemble* and details its stage management, so to speak, does the executive of the Society very great credit.

At the time of writing, the awards of the Judges—Captain Abney, Col. Gale, and Mr. Ralph Robinson—has not been issued, but we should be surprised if in Class A (members: pictures taken since the last exhibition) Mr. S. J. Beckett does not take a medal for his Norwegian series, of which *Sunrise on the Fjords*, in composition, lighting, and richness of tone, is undoubtedly a fine work; with its companion pictures, it is an enlargement from a hand-camera negative. The same exhibitor's *Valley of Odde* is a panorama-like subject, well executed, both as a photograph and an enlargement. In the same class Messrs. J. Carpenter, *Cornflowers and Cypripediums*; Arthur Dean, *Iford Bridge*—a soft and pleasing bit; W. Fenton Jones, *Douglas Harbour*; F. W. Gosling, *An old Doorway Arundel*, and others, contribute good examples.

In Class B, for pictures taken during membership, Dr. Roland Smith's forcible *St. Albans* views; Mr. A. Dean's clever and delicate small work; Mr. Walter Wesson's breezy pictures of *Yachting on the Bure*, catch the eye, and in C (pictures taken at club outings), the pictures throughout are so uniformly excellent that it is hard to separate them. Mr. J. O. Grant's enlargement of the Zoo *Adjutant* is easy, natural, and effective in its treatment of a difficult sitter.

In Class D (portraiture and *genre*), Mr. Robert Beckett, has a series of portraits of which we should give the palm to *Captain de W. Abney* and *A Bethlehem Lady*, the latter especially striking, as as happy in subject and treatment. Mr. G. R. Cleare's portrait of *The Rev. J. de Kewer Williams*, reminds one of Mr. F. Muller's untouched heads, and bears comparison with them, which is high praise. The class is poor in *genre*. There were several classes for lantern slides, in which competition was very keen, and in that for hand-camera pictures Mr. W. P. Dando's exhibits appeared to us as clever as any in a good class.

For such a small class, K (pictures not portraiture and *genre*, open) was of unusual merit, Mr. F. Seyton-Scott's soft dreamy *Kew Gardens*, full of poetry, allied with faultless technique, bearing the stamp of unquestionable skill. In this picture Mr. Scott has happily hit the mean between the two opposing schools of modern landscape photography. There is imagination in the lonely figure pacing *Across the Ploughland* in Mr. Mummery's picture, albeit Dr. Emerson's *Poacher* is irresistibly recalled. Mr. J. A. Hodges, always a good and careful worker, has a charming series, of which the *Shades of Slight*, with its well-managed lights and shadows, is conspicuous as an example of his skill. The best of Mr. Dresser's exhibits is an animated picture of *Amsterdam*, and Mr. A. H. Horsley Hinton shows five of his characteristic landscapes, quite equal to his usual level.

Besides examples of good work shown at Pall Mall and elsewhere by Messrs. Adam Diston, Lyddell Sawyer, S. N. Bhedwar, &c., Class L (portraiture and *genre*), contains many other noticeable exhibits, including *Thoughts over a Pipe* by Robert Terras, a capital head; *Election Time* by J. E. Austin, the subject being the old fellow of the artist's Pall Mall pictures; and two good examples of W. M. Warneuke's large portraiture—*J. L. Toole, Esq.*, and *Miss Alice Kingley*. Mr. W. W. Winter is also largely represented, his best being probably a large portrait of a lady, *Kathleen Mavourneen*, pose, lighting, and expression all alike being very refined. The mauve-like tone of three of Mr. Winter's pictures is novel, but not pleasing. In addition to the now famous series of the *Consecration of a Parsee Priest*, Mr. S. N. Bhedwar shows a fine collection of portraits; and, of the numerous exhibits of Mr. and Mrs. R. B. Lodge, the smaller portrait work is extremely good. Mr. G. Ridsdale Cleare's *Portrait of a Lady*, a nearly, if not quite, life-size picture, is artistically and technically a masterly production. Mr. Byrne also shows several of his exquisite studies of ladies and children.

Messrs. Elliott show their large carbon enlargement of waves, and there is a useful display of apparatus, &c. Among the novelties we noticed were some lantern slides and opals produced by a new print-out process of the Paget Company. On the whole, the Hackney Exhibition deserves to be esteemed as a signal success in all respects.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

10. *Angle of Cone of Illumination with Largest Stop = ——°, giving a Circular Image on the Plate of —— inches diameter. Angle of Cone outside which the Aperture begins to be Eclipsed with Stop C.I. No. —— = ——°, giving a Circle on the Plate of —— inches diameter.*

Diagonal of Plate = —— inches, requiring a Field of ——° (= 2φ). Stop C.I. No. —— is the Largest Stop the whole of the Opening in which can be seen from the whole of the Plate.

If a stop or thin metal diaphragm with a circular aperture is revolved round any axis passing through its plane, and if it is regarded from a little distance, the whole aperture, foreshortened of course, can be seen except in one position in each half revolution; if in a similar way a piece of tubing is revolved about an axis at right angles to its own axis, there is only one position in which the whole of the aperture can be seen, and any movement from this one position will cause the opening to begin to be eclipsed, thus giving it a lozenge-shaped appearance; as the movement goes on, this opening will get smaller and smaller till it is quite obliterated. In looking through a lens as it is revolved about an axis perpendicular to its own axis, it will be seen that, as a rule, something between these two extremes occurs; commencing from a position when we are looking directly along the axis, no other result than foreshortening the opening is at first produced by the revolution of the lens; then comes an angle at which the aperture in the stop begins to be eclipsed, either by the mounting of the lenses, or by fixed diaphragms, &c.; lastly, we come to an angle at which the lozenge-shaped opening appears to vanish, and no light is seen to come from the lens. It is obvious that the intensity of illumination of different parts of the photographic plate varies with the size of the aperture visible from each point; and, neglecting other considerations for the present, there is thus an inner cone, forming a disc where it cuts the plate, in which the illumination decreases regularly from the centre outwards according to a known law: and there is an outer cone, forming an annulus between where it and the inner cone cut the plate, in which the illumination decreases more rapidly than according to the above-mentioned law; very rapidly, therefore, probably irregularly, on account of the aperture of the stop being successively eclipsed by different parts of the mounting, and certainly according to no law that can be readily stated or ascertained. The test now under consideration gives the angles of these two cones.

The outer cone, which we have called the "cone of illumination," gives the extreme angle of the field of the lens without regard to definition, and is what is known to French authors as the *champ de visibilité*. To find the angle of the cone of illumination, the lens is placed in the testing camera, and the observer looks through the small hole in a sheet of tin plate, with which the ground glass has been replaced, as in the last test; the lens-holder is made to revolve about its horizontal axis, and, as the axis of the lens moves away from zero, first in one direction and then in the other, the positions at which all light appears to be cut off are noted; the angle between these two positions as read on the vertical arc, V, gives the angle of the cone of illumination.

In order to ensure correct results, it is necessary that the axis of rotation should pass through the nodal point of emergence. If, in fig. 3,

FIG. 3.

AN_2N_1a and BN_2N_1b represent the extreme rays forming the cone, N_2 and N_1 being the nodal points, it is evident that, in order to measure the angle bN_1a of the cone, the lens must be revolved about N_1, the nodal point of emergence, as a centre. The necessary adjustment is made in the following manner:—The image of a distant object having been thrown on the ground glass, the lens is turned through a small angle about the horizontal axis, the glass remaining stationary. If the movement of the lens gives rise to any movement in the image, then the axis does not pass through the nodal point of emergence, and an adjustment is necessary. This is done by moving the lens-holder in or out, thus making the axis of rotation pass through different parts of the axis of the lens, until the image ceases to show any movement; and this can only be the case when the axis of rotation does pass through the nodal point of emergence. As far as the above considerations are concerned, it is immaterial how far off the small hole in the tin plate is from the lens, but if the horizontal axis has not been made to pass accurately through the nodal point of emergence this want of adjustment will have much the same effect as a small vertical movement between the two readings of the vertical arc. It is evident that the angular error thus produced will diminish as the distance of the point of observation increases; moreover, any distortion at the edge of the plate will make the above theoretical considerations no longer strictly applicable, and will have the same effect as the axis of rotation not accurately passing through the nodal point. In order, therefore, to minimise these sources of error, the tin plate with the hole in it is removed as far as practicable from the lens before the observation is made.

The angle of the inner cone, that is, of the cone outside which the opening of the stop is partially eclipsed by the mounting of the lens, &c., is measured in the same way as above described for the outer cone, and with the same precautions. When looking through the small hole, the positions on each side of zero at which the aperture begins to be shut off, and beyond which it no longer appears as a perfect eclipse, are easily seen, and the angle between these two positions as measured on the vertical arc gives the angle required. The angles of these two cones are generally given when the observation is made with the largest stop supplied with the lens.

The results of these measurements should be considered in connexion with test No. 17, under which heading the general question of the illumination of the field will be discussed. In order to facilitate the consideration of the covering power of the lens, the diameters of the circles which these cones make by cutting the photographic plate, when the focus is adjusted for distant objects, are given in the Certificate of Examination. Having found the principal focal length in the manner to be described immediately, the size of these circles can readily be ascertained by a simple graphical method, which is hardly worth describing in detail.

In connexion with this test it may be convenient to adopt the use of the term *angle of field under examination* (denoted in this paper by 2φ) to signify the angle subtended at the nodal point of emergence by a diagonal of the plate, or the greatest angular distance which could be included in the photograph, supposing the focus to be taken on a distant object. This angle is found by the graphical method mentioned above for determining the diameter of the circles on the plate, and the result is entered on the certificate of examination.

If the illumination of the field is not to fall off rapidly towards the edges of the plate, for the normal use of the lens we should employ a stop which covers (or nearly covers) the plate of the given size with its inner cone; that is to say, we should use a stop not larger than the largest stop the whole of the opening in which can be seen from the whole of the plate. In order to find the largest stop which fulfils the above conditions, the lens is revolved about the horizontal axis until the vertical arc reads half the angle of field under examination, and then the different stops are put in one by one until the largest one is found which is seen not to be eclipsed when the observation is made through the hole in the tin plate. The number of this stop is recorded in the certificate.

The readings taken when measuring the angles of these cones are also utilised for the purpose of adjusting the position of the lens in a manner necessary to ensure accuracy in several of the following tests:—The vertical arc is so arranged that it reads zero when the axis of the lens is horizontal, that is to say, when the axis passes through the small hole in the tin plate from which the observation is made; hence the two readings on the arc when the lens is revolved about the vertical axis, first one way and then the other, so as just to cut off all the transmitted light, should be exactly the same; if they are not identical, the lens-holder is placed in such a position that the reading on the vertical arc is equal to half the difference between them; then it is evident that the mechanical axis of the objective passes through the small hole, or, at all events, cuts the tin plate on the same level as the hole. Now, this small hole in the tin plate is in the same position as the centre of the engraved line when the ground glass is in position. Hence, this adjustment being made, in future tests we may consider that the mechanical axis of the lens cuts the line on the ground glass near its centre.

11. *Principal focal length = —— ins. Back focus, or length from the principal focus to the nearest point on the surface of the lenses = —— ins.*

The following is the method of finding the principal focal length with

* Continued from page 730.

the testing camera:—By means of the mark 0 (see fig. 1) on the three-legged stool, the swinging beam can be brought approximately to a central position; there are also two iron stops, T and T', removable when not wanted, which, when in position, prevent the swinging beam from passing beyond these points. These stops (or, more accurately, the iron plates on the swinging beam with which they come in contact) are capable of adjustment, and thus a means is obtained of allowing the beam to be revolved about A as a centre, through a known angle, with great ease and accuracy. After the focus has been very carefully adjusted for a distant object, and after the beam has been brought approximately to the central position by means of the mark 0 on the stool, the image either of some well-defined object seen through a hole in the window shutters, or of a mark in the collimating telescope, is made to appear on the centre of the engraved line on the ground glass; this can be done by raising or lowering one or more of the legs of the stool, or by moving it laterally; this adjustment being accurately made, the line joining F, the centre of the ground glass, and the centre of the lens, if prolonged, will pass through the distant mark. When once made, this adjustment will hold good, with sufficient accuracy, for all lenses which may subsequently be placed in the testing camera. Now, when the swinging beam is moved from side to side, the image appears to run along the engraved line on the ground glass; the position of the image is first noted when the beam is in contact with the stop T, and afterwards when in contact with the stop T'; twice the distance, as measured on the scale, between these two points gives the principal focal length of the lens under examination.

In order to ensure accuracy, certain precautions must be taken. The object must be so far off that the distance between its focus and the focus of a point in the same direction at an infinite distance is considerably less than the probable error of observation. The chief difficulty of finding the principal focal length in the Kew method, and, indeed, in all methods, consists in obtaining an accurate adjustment for focus; and since, for a given error in focus, the greater the aperture the more diffusion there is in the image, the largest stop should always be used when focussing; but there is no objection to slipping in a smaller stop after the focus is taken so as to obtain as sharp an image as possible, and thus make it easier to read the position on the scale with accuracy.

Before proving that the result above obtained is, in fact, the principal focal length of the lens, it may be as well to give a rigid definition of what is here meant by that expression, as it has often been used in somewhat different significations. The definition here adopted of the principal focal length is the distance between the principal focus for visual rays (or the image as seen by the eye of an infinitely distant point on the axis of the lens) and the nodal point of emergence. The use of the term *nodal point* is, perhaps, open to criticism; under the ordinary circumstances of a photographic lens, the nodal points and the principal points occupy the same positions, and, therefore, either of these expressions might have been used in the definition; but if we take into consideration any imaginary circumstances when these two points would not be identical, as, for instance, if one end of the lens was immersed in water, it will be observed that the Kew method of determining the principal focal length would find the distance between the nodal points and the ground glass, and not that from the principal point; moreover, under these imaginary conditions, it would be the distance of the nodal point from the plate which would chiefly be of value to the aquatic photographer, for the intensity of illumination of his plate would vary as the square of that distance, and not of the distance from the principal point. But it must be confessed that the term was, in reality, adopted because it is that best known in the photographic world, and not on account of such hair-splitting reasons as these.

It now remains to be seen if the Kew method does give the true principal focal length according to the above definition. In fig. 4, let B, A, and C be three very distant points, A being on the axis of the lens, and B and C being at equal angular distances on either side of it; let N_1 and N_2 be the nodal points; let C', F, and B' be the images of these three points on the ground glass, when, if the distance N_2A is great enough, F will not be further from the principal focus than the error of observation, and may, therefore, be confounded with it. The angle, BN_2C, subtended by the points B and C at the lens, can easily be measured, and, since the incident and emergent rays passing through the nodal points are parallel to each other, the angle $C'N_1B'$ is thus obtained; the distance, C'B', that is, the distance between the images of the two outside points, can be also measured on the ground glass: C'B' and $C'N_1B'$ being given, FN_1 can therefore be found; for since, by supposition, the line AN_2 bisects the angle BN_2C, FN_1 is equal to $C'B'/2 \cot C'N_1B'/2$. This, therefore, is a method by which the principal focal length, as defined above, can be measured. But if, instead of having objects at known angles, only one object is observed, and the camera is revolved round the point N_1, through the angle $C'N_1B'$ between the observations, exactly the same result can be obtained; this is the method adopted at Kew. The movement in parallax of the point N_2 is so small that it may be neglected. The advantage of this method is that a collimating telescope can be used as the object, and thus, during dull weather, the work can be carried on indoors. In working with the testing camera, the angle $C'N_1B'$ represents the angle through which the swinging beam is revolved about the vertical

FIG. 4.

pivot; the stops are arranged so that $C'N_1F = \tan^{-1} \frac{1}{2}$, that is, so that $C'B' = 2\ FN_1$; and, therefore, twice the distance C'B' measured on the ground glass gives FN_1, the principal focal length of the lens. The Kew method, therefore, gives the result required.

It might at first sight appear that a considerable error would be due to the fact that the adjustment to the central position is merely made by a rough mark, and that it is only the total angle $C'N_1B'$ (that is, the angle moved by the swinging beam between the iron stops) which is accurately known. It is true that it can only be said that $C'N_1F'$ is approximately equal to FN_1B'; but if $C'N_1B'$ is less than 90°, and if the line N_1F does not differ in direction from the true central position by more than 1°, then the principal focal length obtained in this manner does not differ from the truth, for this reason, by more than 1/17th per cent. As it is considered that this would represent an extreme case, it is therefore evident that this is a negligible source of error.

In order that the Kew method of finding the principal focal length should not be open to any criticism on theoretical grounds, three conditions must be fulfilled: it is obvious that these conditions need not hold good further from the axis of the lens than the points at which the observations were made. 1st. The principal focal surface, or the locus of the focus for very distant objects, must be a plane. 2nd. The image must not be distorted. 3rd. The nodal point of emergence for visual rays should be the same as the nodal point for actinic rays.

In no lens are these conditions perfectly fulfilled; but, before discussing the nature of the errors thus introduced, it may be as well to consider shortly for what purposes and with what degree of accuracy the practical photographer wants to know the focal length of his lens. Two uses to which this knowledge would or could be put have already been mentioned, and we know of no others. In the first place, it has been shown how the numbering of the stops depends on the focal length, and how advantageous is the knowledge of the intensity of the illumination of the plate which may thus be gained. But as, on account of the difference in the amount of reflection and absorption of the lenses, two lenses with the same C.I. number of stop may differ more than ten per cent. in the intensity of illumination in the centre of the field, as in the same objective the difference of illumination of different parts of the field is generally more than twenty per cent., and, as the photographer is seldom able to estimate his unit of exposure within this latter percentage, it can hardly be seriously contended that the focal length must be known with very great accuracy for this purpose. The second object for which the photographer may require to know the focal length is for the use of the tables in which the distance is given at which the object has to be placed to obtain a given enlargement or reduction; it has already been stated that this is not, we believe, a want often felt, except for getting approximate results; but, if the focal length is used for final adjustments in this manner, it should be known with very considerable accuracy.

With regard to the first condition, as to the focal surface being a plane, it should first be stated that it is found convenient at Kew to bring the ground glass into focus when the swinging beam is in contact with one of the stops, thus ensuring the greatest sharpness of image at the points of observation; that is to say, in Fig. 4, the principal focal surface is made

to pass through the points B′ and C′, and, if it is not a plane, it may be represented by the dotted curve C′F_2B′. Under these circumstances, therefore, the principal focus will be at F_2, and N_1F_2 will represent the principal focal length according to our definition; but it has been shown that the observation gives N_1F as the focal length, thus introducing an error equal to FF_2 in the result. It is to be observed, however, that with a lens giving a markedly curved focal surface, the photographer, in order to get a general minimum amount of diffusion, would adjust his focus by looking at the image at a point somewhat more than half way from the centre to the margin of his plate: for example, with a lens covering 50° or 60°, he would focus at a point some 15° from the centre, or at about the position where the Kew observation for the focal length is taken; thus, with such a lens, C′B′, in Fig. 4, would represent the position of the photographic plate; and it is evident that, for all questions of illumination or enlargement, N_1F, or the distance from the plate to the point from which all the light may be supposed to emanate, should be introduced into the calculations, and will give the true results, or, at all events, more nearly the truth than if N_1F_2, the true principal focal length, had been used in its place. Thus, by recording the length N_1F in the Certificate of Examination, we always give more nearly what the photographer practically wants than if the length N_1F_2, or the true principal focal length, had been ascertained. But, in any case, the point raised in this paragraph could, if thought desirable, be met by focussing the plate in the centre of the field when the observation for focal length is made.

The second point raised, as to the theoretical correctness of the principal focal length as found at Kew, is with regard to the distortion of the image, which may be described as the results due to the theory of the nodal points being not strictly applicable except near the centre

Fig. 5.

of the field. In fig. 5, let N_1 and N_2 be the nodal points, F the principal focus, and B″ and C″ the images of the infinitely distant points B and C; if there is distortion, the lines SB″ and SC″, drawn parallel to the incident rays, do not cut the axis at N_1, the nodal point of emergence: let these lines cut each other at S, which may be called the principal point of similitude with regard to the images B″ and C″. This construction represents the Kew method of observation, and therefore SF is the distance found as the principal focal length, thus introducing an error equal to SN_1 in the result; the focal length given is, in fact, the distance from the principal focus to the principal centre of similitude for the part of the plate where the observation is made. But here again, since BN_2C, the cone of incident rays, is spread over a disc on the plate of which B″C″ is the diameter (and not B′C′), the mean intensity of illumination of the plate between these points will vary inversely as $(SF)^2$; and, if the plate covers an angle larger than BN_2C, the C.I. numbering of the stops will give a better indication of the relative exposure on the assumption that SF is the principal focal length than if the true value N_1F is introduced into the calculations. Thus, what has been given in the Certificate of Examination will again be nearer what is practically required by the photographer than if the true principal focal length has been recorded. If, however, the lens is intended to be used for enlargements or reductions, and the final adjustment of the distance of the object is to be made by reference to tables, then, no doubt, the true principal focal length must be accurately given; but no photographer would ever use a lens showing sensible distortion within 15° of the axis, for such purposes, for, if he did, the ratio of the enlargement or reduction would vary sensibly in different parts of his plate; and, if there is no distortion within this distance from the axis, S and N_1 will be coincident, and the Kew method will give accurately and truly N_1F as the principal focal length. Thus, in the only circumstances under which the principal focal length is practically wanted with theoretical truth and great accuracy, it is seen that the results given in the Kew certificate do answer these requirements.

Leonard Darwin, Major R.E.

[To be continued.]

Our Editorial Table.

The "Lecturer" Candle Lamp for Lantern Readings.

This lamp, which is manufactured by Benham & Froud, Limited, forms a useful companion to the lantern. It is constructed on the same principle as their now well-known "Perfection" and "Holiday"

lamps, that is to say, the light from a special candle, which is kept *in situ* by a propelling spring, falls upon a parabolic reflector which, directs the rays downwards as shown by the cut, instead of in a horizontal direction as in the others.

As candles only are employed, the disadvantages of oil are absent. There is a red signal flash provided for by touching a milled-head button to let the exhibitor know when the lecturer desires a plate to be changed. No light escapes into the exhibition-room. The lamp packs up for travelling into the space shown in the second illustration. We have tried the "Lecturer," and find it to be a really useful addition to the *impedimenta* of the lantern exhibitor.

Photo-micrography.

By Edward C. Bousfield. London: J. & A. Churchill.

This forms a second edition of a work by which the author acquired a high reputation as a sound writer on a subject possessing both interest and educational value. It has been rewritten, greatly enlarged, and brought up quite to date. In the chapter devoted to plates and development, Mr. Bousefield considers it a mistake to use very rapid plates, as with slow ones the latitude of exposure is greater and the risk of fogging less. Photo-micrographic cameras are shown and their characteristics described, while of stands there are not a few. Object glasses, oculars, and condensers are all discussed with due fulness, although he considers that a condenser as free from spherical and chromatic aberration as an objective of good quality is still a desideratum. The nearest approach to it is probably to be found in using as a condenser an objective of somewhat lower power than the one attached to the microscopic tube.

There is so much that is good and practical in this work (which contains many illustrations) that it can be strongly recommended to all who purpose devoting themselves to this department of photography. 174 pages.

The Optimus Lantern Objective.

This new lens, by Messrs. Perken. Son, & Rayment, has a singularly flat field combined with great brilliance of the image. The corrections by which these properties have been secured have not been obtained at the cost of its utility as a *carte* portrait lens, for the coincidence of the chemical and visual foci, not always found in some lantern objectives, is here perfectly achieved. The form of the combination is essentially that of Professor Petzval's, subject to slight alterations consequent upon the improvements recently effected in optical glass. Although for lantern purposes it works with full aperture, yet it is provided with a case of stops to serve the purposes of copying or ordinary photographic portraiture. The lenses are two inches in diameter, with an equivalent focus of six inches.

Trade Catalogues, &c., Received.

E. G. Wood's (74, Cheapside) catalogues of slides, optical lanterns, and dissolving-view apparatus (144 pages) contains no fewer than 122 pages devoted to lists of slides duly classified, the remaining portion containing descriptions of apparatus.

In the catalogue of J. H. Steward (406, Strand), while there is a considerable portion devoted to slides, yet does the apparatus section preponderate. It includes several specialities of Mr. Steward.

The ability of W. C. Hughes (82, Mortimer-road, N.) to compile a wondrously large catalogue of lanterns and appliances is not growing less. His new one is very large and comprehensive. It contains, as a supplement, a clearance sale list of lanterns, slides (coloured and plain), jets, and other apparatus, at considerable reductions from the original prices.

A catalogue just received from C. C. Vevers (Leeds) is, like those just previously mentioned, devoted exclusively to "magic and optical" lanterns, slides, and accessories, although a supplement consisting of new apparatus to his photographic catalogue accompanies it.

In this month's number of Fallowfield's *Remembrancer*, as might be expected from the season, is catalogued much that relates to the optical lantern and to flash-lamps, as well as to albums, scrap-books, and job lines.

The Provisional Catalogue of Newman & Guardia's (71, Farringdon-road, E.C.) hand cameras and shutters contains a description of their changing box and carriers, together with their aluminium blind shutter with Newman's automatic pneumatic regulation.

Outlines of Organic Chemistry.

By Clement J. Leaper, F.C.S.

This work, which is professedly written for schools and classes connected with the Science and Art Department, is, we gather from the preface, laid down on such a plan as to take up about fifty hours, viz., twenty lectures of an hour's duration, and twenty laboratory practices, each lasting an hour and a half. In each of the twenty chapters experiments are described, terminating with a few questions arising out of each. We have on a previous occasion expressed our sense of the ability and talent of the author as a writer of works cognate to the present, and have now merely to add that for students of organic chemistry this small volume will prove eminently useful. It is published by Iliffe & Son, St. Bride-street, E.C. 120 pp. Price 2*s*.

Field-path Rambles round Bromley.

By Walker Mills. R. E. Taylor & Son, 19, Old-street, E.C.

This little pamphlet, descriptive of possible ramhles in the charming Kent country near London should not only prove useful to pedestrians, but also to photographers in search of the picturesque. It is, we gather, to be followed by others.

Messrs. Sharp & Hitchmough, Liverpool, send us a sample piece of their "Aptus" opaque lantern screen, prepared with a special flexible material on strong canvas. This will prove a serviceable screen, being white, durable, and not likely to get creased. Other screens issued by this firm, *e.g.*, their washable cloth, one which is made in one piece up to eight feet and mounted on rollers top and bottom, will also prove useful.

THE MADDOX TESTIMONIAL FUND.

After a good deal of accidental but unavoidable delay the Testimonial expressing the sentiments of the subscribers to the above Fund has been sent to Dr. Maddox, the cheque alluded to having been handed over to him many months ago. The actual sum is somewhat in excess of 400*l*., as a few subscriptions came in after the Fund was closed; but these amounts have been passed on to the solicitors of Dr. Maddox, and have been added to the subscription list, which was not circulated among photographers of Great Britain and the United States, but covered the Continent of Europe, India, &c. When the latter list is closed we hope to intimate to the photographic public the result of the appeal to countries other than those included in this present notice.

The Committee thank the subscribers heartily for their handsome response to the appeal, and it must be a pleasure to all to know that the gift was of much use to Dr. Maddox, and is accepted by him with great gratitude.

The following is a copy of the document, which is on parchment, and neatly illuminated. Andrew Pringle, *Hon. Secretary*.

This Testimonial is presented to Dr. Richard Leach Maddox with a cheque value 400*l*.—four hundred pounds—raised by voluntary subscriptions in Great Britain and the United States of America, in recognition of his services to photography, and especially of his investigations in connexion with gelatine emulsion. Signed on behalf of the subscribers by the Committee:—

James Glaisher, *Chairman*.	A. Clifford Mercer.
W. de W. Abney.	Henry Sturmey.
W. S. Bird, p.p. the Autotype Co.	J. Traill Taylor.
G. Davison.	W. H. Walker.
A. Haddon.	H. T. Wood.
A. H. Harman (for the Britannia Works Co).	Frederick York.
	Thomas Bedding.
Charles W. Hastings.	Francis Cobb, *Hon. Treasurer*.
T. C. Hepworth.	Andrew Pringle, *Hon. Secretary*.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
November 21 ...	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
„ 21 ...	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.
„ 21 ...	Hastings and St. Leonards	
„ 21 ...	Leeds (Technical)	Mechanics' Institute, Leeds.
„ 21 ...	Richmond	Greyhound Hotel, Richmond.
„ 21 ...	South London	Hanover Hall, Hanover-park, S.E.
„ 22 ...	Great Britain (Technical)	50, Great Russell-st., Bloomsbury.
„ 23 ...	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
„ 24 ...	Camera Club	Charing-cross-road, W.C.
„ 24 ...	Hackney	206, Mare-street, Hackney.
„ 24 ...	Halifax Photo. Club	Mechanics' Hall, Halifax.
„ 24 ...	Hull	Royal Institution, Hull.
„ 24 ...	Ireland	Rooms, 15, Dawson-street, Dublin.
„ 24 ...	Liverpool Amateur (Annual)	Crescent Chambers, 3, Lord-street.
„ 24 ...	London and Provincial	Champion Hotel, 15, Aldersgate-st.
„ 24 ...	Oldham	The Lyceum, Union-street, Oldham.
„ 25 ...	Cardiff

„ 26 ...	Putney	High-street, Putney.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 10,—Mr. E. W. Parfitt in the chair.

Questions.

The following question from the box was read: "I developed two under-exposed plates, and intensified them by bleaching them with a solution of mercuric chloride, 100 grains; potassium bromide, 100 grains; water, 10 ounces; then washed for several minutes and immersed in a solution of silver nitrate, 100 grains; water, 10 ounces; with sufficient cyanide of potassium to dissolve the precipitate. One negative is of a reddish colour, while the other is black and white by reflected light, and slightly red by transmitted light. Can any one account for this? Is it due to insufficient washing previous to intensification?"

Mr. W. E. Debenham could not see why one colour more than another should make any difference in the printing so long as the shadows were clear, neither did he find it so.

It was understood that the question should be deferred for the production of the negatives.

Question No. 2: "Could wash-leather be employed to make the valve of a gas cylinder gas-tight?"

Mr. T. E. Freshwater observed that, if the cylinder was not properly valved, no wash-leather would stop the gas.

Question No. 3: "What is the best developer for photomicrography?"

Mr. FRESHWATER always used pyro-ammonia, and said that the plate should be thickly coated.

LITHIUM TONING BATH FOR GELATINO-CHLORIDE.

Mr. C. H. COOKE exhibited several prints on Eastman Solio paper toned with a bath consisting of—

Gold chloride	2 grains.
Lithium carbonate	1 drachm.
Water	8 ounces.

The bath was ready for use as soon as made. He washed the free silver out of the prints before toning.

The CHAIRMAN said the prints had a nice tone.

UNIFORMITY OF RESULT WITH GELATINO-CHLORIDE PAPER.

In reference to a brief discussion on this subject at the previous meeting, Mr. JOHN HOWSON said that uniformity of result on gelatino-chloride paper could be as readily obtained as with albumen, given the same amount of knowledge of the subject. He would show some results as obtained by a professional photographer, consisting of four or five dozen prints which were "overs" in the studio work—that is, a man may have ordered two or three dozen copies, and the photographer had printed two or three dozen over. He thought the prints showed that uniformity of tone could be as readily obtained as with albumen. Of course, gelatino-chloride was somewhat new, and there was something to learn; but with the necessary experience it was just as feasible to get uniformity of tone with gelatine as with albumen.

The prints shown were the work of Mr. Midwinter, of Bristol, to whose method of working gelatino-chloride, as detailed in a recent number of this JOURNAL, Mr. Howson made reference.

Mr. J. R. GOTZ remarked that he had seen many albumen prints blue in the lights.

Mr. C. H. COOKE asked if the colour of the pictures could not be altered?

Mr. HOWSON said this might be done by toning for a shorter time. They could have a range of tone from warm brown to purple black.

Mr. DEBENHAM said many experienced a difficulty of this kind—that the prints would appear reddish-brown and then go into the blue stage.

Mr. HOWSON said this would happen if the toning bath were too rapid. The bath to be in proper working order should be two-thirds old and one-third new, and the toning could then be stopped at any stage.

Mr. J. R. Gotz exhibited and described his Kangaroo changing box. (This was fully described in a recent number.)

AMIDOL.

The CHAIRMAN said he had been making some experiments to ascertain if amidol gave a greater amount of detail or increased the sensitiveness of plates more than other developers. He passed round seven plates which had each had fifteen seconds' exposure to a sensitometer screen at a distance of six feet from a Bray's No. 7 burner. The plates had been developed with different developers, his conclusion being that there was no more to be obtained by using amidol than pyro and carbonate of soda.

Mr. HOWSON certainly found that for studio work amidol was preferable in some respects to any other developer he had come across. It seemed to give somewhat better results in detail in the shadows without the high lights being blocked. One defect, especially for lantern work, was that it did not yield density nearly so readily as pyro-soda without prolonged development; therefore he would not use it except for normal development and exposure, because in prolonged development of under-exposure one would be apt to get fog. It was, besides, absolutely necessary to use a small amount of bromide as a restrainer, say, half a grain to one ounce of solution, otherwise one would be bound to get fog with the stock solution with most plates he had tried. If he had plates to develop of which he was in doubt, he would certainly use pyro-soda in preference to amidol. For bromide paper and for lantern plates it certainly had advantages over hydroquinone or any other developer he had met with. He would not recommend it in preference to ferrous oxalate, but it was better than hydroquinone, as it did not clog the shadows, and the deposit of the image had an exceedingly fine grain.

The CHAIRMAN having mentioned the difficulty of keeping a stock solution of amidol without discolouration,

Mr. P. EVERETT suggested that a stock solution of the sulphite of soda be kept and the amidol dissolved in it as required for use.

FLASHLIGHT PHOTOGRAPHY.

Mr. E. MILNER, being unable, owing to an unavoidably late arrival, to deliver his promised paper on *Outdoor Experiences* (which was consequently postponed for a fortnight), was invited to speak on *Flashlight Photography*. He said he had that evening taken the Exhibition of the Leytonstone Camera Club by means of a continuous flash-lamp of his own invention and a screen. It was a one-flame lamp. He had recently exposed a plate with it at the Adelphi Theatre for three seconds, with the lens at *f*-32, and got a very well-exposed picture indeed. The picture at Leytonstone Camera Club had less exposure than this. The lamp would consume three or four drachms of magnesium in three seconds, an ounce not lasting more than thirty-five seconds. He had tried aluminium, but could not burn it. With his lamp the magnesium could either be burnt quickly or slowly. The flame was about two feet six inches high and one and a half feet across.

The meeting then terminated.

Holborn Camera Club.—November 11, Mr. E. H. Bayston in the chair.—Mr. W. E. Debenham gave a lecture and practical demonstration on *Transparencies by the Carbon Process.*

North Middlesex Photographic Society.—November 14, Mr. F. W. Cox in the chair.—About forty-five members were present. Mr. J. Traill Taylor addressed the Society on Photographic Optics. He said that in preference to giving a lecture, he would have a gossip with the members on the various types of photographic lenses. The "gossip" took the form of an account of the different forms of lenses which had from time to time been evolved. Beginning with the simple bi-convex lens used in the camera obscura, he exhibited examples of the various lenses in the chronological order in which they have been produced, the earlier examples having been ground, the crown from window bull's-eyes, and the flint from bottoms of tumblers. He explained, by aid of the examples and by the blackboard, the effect of the different curves and combinations, and showed that in the earliest examples some of the latest inventions had been forestalled. He showed the tele-photographic lens, and the lenses from an opera-glass, with which he had made his experiments in 1868, and the results of which were given in the ALMANAC for 1869, and gave valuable information to those who desired to modify their lenses for emergencies. He pointed out that, in constructing a tele-photographic lens, it was necessary that, when the image-forming lens and the lens of negative focus were laid one on the other, the combination should make a diminishing glass. Prints of breaking waves, taken with a spectacle lens by Mr. Henry Sutton, were shown. Much interest was taken in the types of lenses exhibited, and particularly in the spectacle lens used by Mr. Taylor when he first began photography. Several questions were asked and fully answered, and a vote of thanks to the lecturer carried with acclamation. The remainder of the evening was devoted to making arrangements for the annual Exhibition, to be held on Monday, the 28th inst.

Hackney Photographic Society.—November 8, Mr. A. Barker in the chair.—Mr. William Smith showed Tylar's new form of lantern slide carrier (which was afterwards successfully worked in the lantern) and lantern slide printing frame. A question was asked as to why a reduced slide showed unevenly and dark in centre. The HON. SECRETARY said if artificial light was used probably it was caused through the light being held too near to the negative. Mr. Smith asked whether opal was better than ground glass for this work. Mr. BECKETT observed that it stopped the light somewhat more, but the illumination was better. The Hon. Secretary announced that the next ordinary meeting would be on the 22nd, when the Autotype Company had promised a demonstration.

Putney Photographic Society.—November 7, Dr. Sheppard in the chair.—Mr. BUCHANAN WOLLASTON gave a lecture and demonstration on *Platinum Printing Processes.* The lecturer stated that the "hot bath" was now practically a thing of the past, being superseded by the new cold-bath process. He claimed for the latter several advantages, among which were superior keeping qualities, greater simplicity of manipulation, and more control over the results. Unlike the hot-bath process a good print could be made from practically any negative, in fact, he had found that, by modifying the method of printing, the developer, and its application, an excellent result could be obtained from a negative that would not give a passable print by any other process. Mr. Wollaston laid special stress on the absolute necessity of keeping the paper bone dry before, during, and after printing, if full advantage were to be taken of its capabilities to give brilliant results. For this purpose the paper must, until development, be stored in special boxes containing calcium, care being taken that, as soon as the calcium becomes softened by the absorption of moisture, it should be taken out and thoroughly dried. In order to keep the paper dry during printing, it is also absolutely necessary to use a vulcanised rubber pad placed in contact with it in the frame. Results depend very largely on these precautions being carefully observed, for, should the paper have absorbed moisture, there will be a corresponding tendency to mealiness, appearance of grain in the shadows, and a general lack of vigour and brilliancy in the print. In the hot-bath process the difficulty of judging the depth of printing was not infrequently found to be a stumbling-block to the beginner, but, as the new paper may be printed until full detail is fairly visible, no great difficulty should be experienced in this direction. Mr. Wollaston said that very thin negatives might with advantage be printed under blue, and hard ones under signal-green glass, and that printing generally be done in a bright diffused light by preference. The prints can be developed by immersion, floating, or by brush. The two former require no explanation, but it should be noted that they usually give cold tones. The lecturer evidently prefers to develop by the brush, as by this method he has more command over the development, and thereby obtains a fuller scope for the artistic treatment of the subject. The normal developer consists of oxalate of potash, one pound dissolved in fifty-four ounces of hot water. For use this should be diluted by adding an equal quantity of water. For brush development, the addition of glycerine in the proportion of one part normal oxalate developer (one pound to fifty-four ounces), one part of glycerine, and two parts of water, was recommended. Mr. Wollaston then proceeded to develop prints by the brush method. In order to keep the paper flat it was temporarily mounted on a slab thinly coated with plain glycerine. The developer was then applied by means of a camel's-hair brush, which was wetted with fresh developer between each stroke, care being taken that each succeeding stroke should overlap the previous one. Should any part of the print now be seen to require strengthening, a developer without glycerine should be used for the purpose. Should it be anticipated from the nature of the negative that any part has been over-printed, detail and transparency in the shadows can be retained by first covering those parts of the print with a thin layer of plain glycerine rubbed on evenly with the finger, the development being afterwards proceeded with in the usual way. Still further control can be obtained by covering the whole of the paper with plain glycerine previous to development. It will be understood that the glycerine acts as a retarder, much the same as bromide acts in an ordinary developer, and it should also be noted that length of development tends to produce warmth of tone. Should it be desired to vignette the picture, it can be done to any shape in an artistic manner and with great ease by simply omitting to apply the developer to the parts that are desired to remain white, the softening of the edges being done gradually, or by cross hatching in the manner of a crayon drawing. The vignetting may be done after the picture has been printed to the edges. When development has been completed, the prints, without previous washing, are immersed face downwards in a bath of dilute *pure* hydrochloric acid (one part to sixty parts of water), and allowed to remain for five minutes, then removed to a second acid bath for about ten minutes, afterwards to a third for about fifteen minutes. The prints must be finally washed in at least three changes of water for about a quarter of an hour.

A pinch of washing soda should be added to the second water. The prints are then dried in the usual manner.

West London Photographic Society.—November 11, the President (Mr. John A. Hodges) in the chair.—Five new members were elected. Mr. E. J. Wall read a paper on *A Comparison of Printing Processes.*

Bolton Photographic Society.—November 9, Mr. William Banks in the chair.—Mr. S. G. BUCHANAN WOLLASTON gave a lecture on *The Powers of the Platinotype Company's new Paper for Cold Development*, illustrated with a practical demonstration of the various methods of modifying the developer, and showing how completely the image could be held in control.

Leicester and Leicestershire Photographic Society.—November 9, the President (Mr. F. G. Pierpoint) in the chair.—Mr. THOMAS SCOTTON, of the Derby Society, then gave a demonstration of the *Cold Bath Platinotype Process*, prefacing his demonstration with a lucid description of the various processes. The demonstration was perfectly successful, and exceedingly interesting and useful, the principle of retarding development locally by the use of glycerine applied to the part desired to be retarded was very markedly demonstrated. After the demonstration the PRESIDENT (Mr. Pierpoint) read a paper entitled, *A Tour through the Dukeries*, illustrated with some well-executed slides.

Liverpool Amateur Photographic Association—November 10.—Mr. C. F. BUDENBERG, of the firm of Schaeffer & Budenberg, Manchester, gave a lecture before this Society upon the subject of *High-Pressure Gas Gauges*, illustrated by experiments with apparatus, which the lecturer brought for the purpose. Mr. Budenberg explained that there was no occasion for the least risk of danger in the use of a gauge so long as the user took care to ascertain that he got a well-made article. He stated that, while inferior gauge-tubes were made out of ordinary drawn steel tubing roughly finished, the reliable instruments were made from pressed octagonal steel bars bored, and afterwards carefully turned, and polished inside and outside. By fixing one of each kind of instrument upon a pressure-pump, he showed that the first was strained and rendered unreliable by being submitted to the ordinary pressure, and would easily have burst if the pressure had been slightly increased; but the second, after a pressure of several tons, returned to its original position without showing a fraction of displacement. Mr. Budenberg then referred to chemical explosions which had been caused by turning the full force of oxygen into a gauge in which traces of oil remained. The intense heat generated by the sudden rush of gas rapidly consumed the oil, and an explosion was the result. This action was shown by placing a piece of wood in a brass tube, which was attached to a cylinder charged with air. When the valve was suddenly opened the rush of air ignited the wood. The best gauges, the lecturer explained, were now made with a check, to prevent this sudden inrush of gas, so that, even if they were charged with inflammable oil, an explosion could not result. His firm, however, did not allow oil to touch their gas-gauges. Mr. Budenberg strongly deprecated complicated connexions with cylinders, his opinion being that the connexion between the cylinder and the regulator should be as short and as simple as possible.

Manchester Photographic Society.—November 10, the President (Mr. Abel Heywood) in the chair.—Mr. W. N. Sherburn was elected a member. The President showed a very simple contrivance for holding sheets of paper during drying. It was an article introduced to the printing trade, but Mr. Heywood considered it a very good arrangement in place of the American clips usually used to suspend prints. The appliance consisted of a rail of wood about $2\frac{1}{2} \times \frac{3}{4}$ inches, having on one edge a series of oval-shaped fret cuts, in each of which were retained loosely by tinned crossed wires common marbles or, as schoolboys term them, "alleys." A sheet of paper pushed up into one of the slots or cuts is held securely by the marble pressing against the edge thereof, and cannot be removed by a downward pull, which only tends to tighten the grip of the marble, but a slight side pull easily removes the sheet. The same arrangement is made in single squares of wood, having one paper-holder and a spiral fret to enable the square to be slung on a line. The remainder of the evening was devoted to a discussion on lantern slide making, Mr. J. Wood and Mr. Whitefield giving a very full account of their methods, which were directly opposite, Mr. Wood's plan being to give a full exposure and rely on modifications of his developer, whilst Mr. Whitefield relied on varying the exposure and using a normal developer. A number of the members contributed to the discussion, the majority being in favour of eikonogen or eikonogen modified with hydroquinone for developing. The result of the discussion showed that care in the manipulation was the main factor, as the exhibition of examples showed good results by very varied methods. Mr. Whitefield gave the following formulæ for developing for line work when good black lines on a clear ground were required, though not quite equal to wet collodion. The results were very good, and better than the usual method of treatment:—Hydroquinone, 4 grains; potassium bromide, 2 grains; sulphate of soda, 12 grains; sodium hydrate, 4 grains; sodium carbonate, 12 grains; made up to 1 fluid ounce with water. Use good plates, develop fully, and clear with the alum and acid bath.

National Association of Professional Photographers.—A meeting of the Council of the National Association of Professional Photographers was held at Anderton's Hotel, Fleet-street, E.C., on November 9, Mr. Thomas Fall in the chair.—The PRESIDENT said that it was most difficult to fix a time and place for meeting that should suit the convenience of all members, and that, though there was such a representative gathering from all parts of the country, he regretted the unavoidable absence of many. Several of those who were unable to attend had written most hopefully and encouragingly. He then dealt with the case of a firm of enlargers who had refused to agree to the Association's terms *re* prices "for the trade only." Several members strongly expressed their opinions on the subject, and, while regretting that the Association did not include practically the whole of the profession, which would enable it to bring such a house to reason, pointed out that there was only one course for members to adopt, and that even a couple of hundred of the principal men could exert some appreciable influence. Mr. J. CROSBY (Rotherham), followed by Mr. J. HUBERT (Hackney), strongly urged the necessity of increasing the numerical strength of the Association. Mr. Crosby said that Leeds, Sheffield, and Hull had formed local centres, but that, until they had the substantial support of London, solid progress was impossible. The SECRETARY read his report of work done since February last, in which time fifty new members had been added to the Association. He reported on the visit paid by the President, Mr. Whitlock, and himself to the Convention, which had resulted in the acquisition of a few members. He had personally canvassed Birmingham, Wolverhampton, Newcastle-on-Tyne, Sunderland, and other towns, and had three times met the executive in London without any expense falling upon the Association. Mr. W. GILL (Colchester) said that one volunteer was worth two pressed men, and that it was possible to do too much in the way of canvassing folks who were unwilling to join. He thought more attention should be turned to making the Association of greater practical value, and to making its value more apparent, so that outsiders would not need pressing to come in. Mr. MARTIN (London) said that the idea of *esprit de corps* should be pressed forward more than mere money or business advantage. Mr. J. HUBERT (Hackney) said that, though a previous speaker had disparaged personal canvass, he thought that a personal application would show the value of the Association to many men who had simply not troubled to consider about it. For his own part, he would canvass his own district, and report results to the next meeting. He urged other members, especially those in London, to do the same, and added that he was sure all the London men worth having would be solid in favour of the Association if its objects were personally explained to them. If no other London men would undertake the work, he would devote all his spare time to it, and, if necessary, continue his labours in evenings and other odd times, until he had worked the whole of London. (Applause.) Mr. H. J. Godbold (Hastings), Mr. Spink (Brighton), and other members promised to canvass their own districts. The PRESIDENT said that, so far as he had been able to call upon the men in the West End, his success had been beyond his anticipation. Perhaps the bill of fare presented by the Association had not been so attractive as it might have been. They had thought it well to simply attempt the gathering of a strong body of photographers who should decide the channel in which to direct their practical efforts, rather than to attempt to redress abuses before they knew what strength they had to rely upon. They had done some work in the past, which had been reported from time to time, but now, perhaps, they might offer further advantages. As Mr. Gill had said, they must look to the young men, and to these he would point out that membership of the Association, which enabled them to seek and to obtain the advice of many of the leading men in the profession, was in itself valuable. He (the President) would have liked to see professionals more generally eager to join the Association, but he was very well satisfied when he considered the character of the membership. They were not a heterogeneous mass, but representative men from all parts of the kingdom, and formed an excellent nucleus for a strong and vigorous organization. A suggestion had been received from Mr. H. Snowden Ward, who was not a member of the Association, that the Commissioners of the World's Fair Congress on Photography would appreciate the appointment of one or more delegates from the National Association of Professional Photographers. It was proposed, seconded, and unanimously carried that the President, and Messrs. Charles H. Evans, W. Gill, and W. Battersby be delegates to represent the Association, and to report on the proceedings of the Congress. It was proposed by Mr. W. Gill, seconded by Mr. Bromwich, that the thanks of the Association be tendered to the Manchester *Spy* for its exposures of the doings of Mr. Sauvy, a Manchester photographer. The subject was commented on by several members, including the President, who said that, though photographers were no better than other men, he thought that the photographers of London would not have suffered such a man as Sauvy to remain amongst them so long as their Manchester brethren had. If the rumour that Sauvy had returned from his flight were true, he hoped that Manchester photographers would not rest until they had made it impossible for such a man to continue in business. The vote was unanimously carried. It was proposed by Mr. J. Crosby, seconded by Mr. Glaisby, that the next annual meeting be held in Manchester.

Aberdeenshire Amateur Photographic Society.—The progress made by the Aberdeenshire Amateur Photographic Society, which has been but a little over a year in existence, is evidenced both by the variety and the merit of the Society's first competitive exhibition which opened on November 12. The majority of the photographs were shown in handsome frames, and in some cases the mounting was very artistically carried out. The prints represented all the different methods of photographic reproduction—silver, bromide, platinotype, printing-out paper, and carbon; and a number of the figure studies and scenes and portraits were of exceptional interest, both as regards artistic treatment and technical execution. The prints were judged by Messrs. Ewing and Morgan, whose awards were as follows:—Class 1, half-plate landscapes, silver medal, L. M. Gibb, Victoria-street; bronze medal, E. L. Brown, 2, Esslemont-avenue; highly commended, E. L. Brown, 2, Esslemont-avenue; commended, L. M. Gibb, Victoria-street. Class 2, whole-plate landscapes, silver medal, J. Milne, Devanha-terrace; bronze medal, W. Gibson, London; highly commended, W. Gibson, London; commended, J. Milne, Devanha-terrace. Class 3, portraiture and figure study, silver medal, J. Milne; bronze medal, W. Gibson, London; highly commended, J. Milne; commended, E. L. Brown, 2, Esslemont-avenue. Class 4, seascape and river scenery, silver medal, J. Milne; bronze medal, W. A. Hawes, Gilcomston-park; highly commended, W. A. Hawes, Gilcomston-park; commended, W. T. Moffatt, Beaconsfield-place. Class 6, enlargements, silver medal, W. Moffatt, 7, Queen's-gardens; bronze medal, W. Ramsay, Dyce; highly commended, J. Milne, Devanha-terrace; commended, J. Anderson, Cults. Class 7, hand camera work, bronze medal, E. T. Smith.

Edinburgh Photographic Society.—This Society opened its annual exhibition of members' work, combined with a series of the best attainable loan work, on Thursday, November 10. They are to remain, for a fortnight, freely open to members and the public. The meeting was opened in the somewhat novel way of holding a smoking concert, at the commencement of which Mr. ALEXANDER AYTON (Vice-President) said that this meeting was somewhat of a new departure, and as this was his first appearance in the chair, he took the opportunity of thanking them for placing him in the position. He stated that it was the first social evening the Society as a body had held, and he thought the movement was one which should be encouraged and repeated.

An attempt was to be made by the Council to increase the utility and extend the usefulness of their meetings and their work as a body; they intended this to be a working session, and had appointed a committee to organize a lantern section, which would hold a monthly meeting for lantern work only. There was also to be a series of lectures and experimental meetings for the benefit of the younger members of the Society, but which would not interfere with or clash with the ordinary monthly meetings. They were now in the proud position of having a membership—over 400—by far the largest in the United Kingdom, and they had also any amount of talent in the body, which the Council intended to make full use of to bring it out—in fact. With the encouragement they had got, they thought they might face the question of making the exhibition an annual one, and there was no reason why they should not have one that would rival that of the parent Society in Pall Mall, London. During the evening a number of songs and recitations were given by Messrs. Crooke, Lumsden, Gardner, Boswell, and others. The exhibits are divided into four classes:—I. Those pictures sent for exhibition only, and those got by the Council, which have already secured high awards elsewhere. II. The pictures taken during any of the 1892 Saturday rambles. III. Figure studies from negatives, taken since 1st November, 1891. IV. Landscapes from negatives, taken since 1st November, 1891. The best picture of each of the three latter classes are to have medals awarded. The pictures in these three classes number about 200, and the method of awarding judgment is by the member filling up a schedule, copies of which are lying in the rooms and must be filled up before November 22, 1892. It takes this form, which might with advantage be copied by other societies.

In my opinion, the best pictures are as under:—

Class II.	*Class III.*	*Class IV.*
No.	*No.*	*No.* .....

Then follow member's name, address, date. The pictures themselves are only distinguished by a number, and the author by a motto or *nom de plume*, so that, except by the mannerism of the artist, all knowledge of the personality of the producer is cut off. Nothing could be devised better adapted to get the true opinion of those members who visit the rooms, and care to give their judgment after having examined the pictures. Mr. F. P. Cembrano has sent four landscape studies, printed in platinum, on rough paper, which have taken first-class awards at exhibitions in London, New York, Amsterdam, and Brussels. The pictures have a characteristic Corot effect. Mr. W. Bedford has sent duplicates of three pictures lately exhibited in the Pall Mall Exhibition of the London Photographic Society. Printed in carbon, of sepia tint, and on rough paper, they have all the appearance of the work of an old Dutch master. Mr. George Davison, President of the Photographic Convention of Great Britain, sends twelve landscape pictures of the Emersonian school. Mr. Ralph Robinson sends three large pictures—landscapes with figures—which will be useful to the members as studies in composition. Mr. Lyddell Sawyer sends two large figure compositions subjects, which illustrate the charming effects that may be produced by attention to lighting; Mr. F. Sutcliffe, a series of very beautiful landscape enlargements; and Mr. Adam Diston, a few exhibits of composition *genre* subjects. Of the work of the members, the most striking, is the large group of the Photographic Convention, which was taken in Princes-street-gardens, Edinburgh, by Mr. Ayton, the chairman. Though there are over 130 figures in the group, each is a good portrait.

Edinburgh University Photographic Society.—The annual business meeting was held in the Society's rooms, Bristo-street, which have been renovated and improved during the recess. The expense, we understand, has considerately been borne by several of the professors who take an interest in photography. The Professor of Chemistry (Dr. Crum Brown) presided. He called attention to the exhibited works of the members, and urged close attention to the scientific, as well as to the artistic, side of this fascinating study, than which no young man could have a better hobby, or one more likely to lead to steady improvement of mind and morals. The evening concluded, after appointment of office-bearers and hearing and adopting Secretary and Treasurer's reports, with a friendly criticism of the members' work as exhibited.

Glasgow Photographic Association.—November 3, Mr. William Lang, jun., F.C.S. (President), in the chair.—Messrs. A. B. Fulton and James McGlashan were elected members, and the office-bearers for session 1892-93 were appointed. Mr. J. Craig Annan read a paper, *Progress of Photography—A Critical Inquiry.* A discussion followed.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 20,119.—"Magnesium-light Cartridge for Photographic Purposes, and Process of Producing same." Complete specification. E. Hackh.—*Dated November* 3, 1892.

No. 20,156.—"An Improvement in the Production of Names, Titles, and other Inscriptions on Photographic Prints, Transparencies, and Lantern Slides." A. Gray.—*Dated November* 8, 1892.

No. 20,253.—"An Improved Photographic Dark-slide Recorder." J. E. Thornton and E. Pickard. *Dated November* 10, 1892.

No. 20,254.—"Improved Arc Lamp for Photographic Purposes." H. Bown and W. Harwood. *Dated November* 10, 1892.

No. 20,418.—"Improvements in Photographic Machines." W. J. Baker.—*Dated November* 11, 1892.

Correspondence.

AMIDOL.

To the Editor.

Sir,—From two letters which appear in your last issue, on p. 735, "W. S. P." and "Othello" are in difficulties with the above (to me) valuable developer. I therefore send the following hints, which may be of service to the above as well as other interested readers.

The stock solution should be mixed thus:—The sulphite of soda is dissolved in half the water used, and the amidol is dissolved in the other half. The two solutions are then mixed together, and are ready for immediate use.

I have used the above developer for the last two months or so with complete success, and, except in cases of great under-exposure, have found it quite unnecessary to intensify.

I have used both the stock solution recommended by the vendors, and one mixed according to my own ideas, with equal success on Marion's Ordinary, Ilford Ordinary, Matchless, Paget XXXXX, Fry's sixty times ground-glass plate, and the Upton. I think a very impure sample of sulphite of soda must have been used, or sulphate of soda or some other chemical was supplied by mistake, or impure water may be the cause. Use only pure distilled, or fresh rain water filtered, for mixing either this or any other solution for photographic purposes. The very fact of your stock solution being nearly colourless seems to indicate that you have used some other chemical and not pure sulphite of soda. My stock solution discoloured in about twenty-four hours, and has got deeper and deeper in tint up to a certain point as time went on, more than a month, but seemed to work as well and as clean as ever, although perhaps somewhat slower in action. I develop for from about four to thirty or more minutes, according to the density required and the exposure given. The shorter the latter the longer the former usually takes with this developer, as with every other I know of, although it is much quicker in action than most developers.

Rock the dish well during the development, and pour the developer off for a minute or two, say every two to five minutes or so (during long development), still moving the dish as if the developing solution was in it. This is to prevent possible markings on the negative, caused by more solution sticking to some parts of it than to others. It is surprising how much detail and density makes its appearance by adopting this simple plan.

With about four ounces of solution (the exact strength of which I do not know, but, judging by its action when compared with another solution of a certain known strength, I believe it to contain about eight grains of "amidol" to each ounce of water), I have developed quite two dozen half-plates during the time stated above, most of which had received exposures of one-sixth to one-tenth of a second on some prize dogs at rather close quarters, out of doors, rapid rectilinear lens, twelve inch equivalent focus, *f*-12 to *f*-16 stops, at midday the latter end of October and the first few days in November. The solution is a rather deep ruby colour, and the plates used were of ordinary speed, probably about 30 on Hurter & Driffield's actinograph.

The solution above mentioned is only used in cases of very quick exposures, as mentioned above, on subjects taken in a very bad light, or on plates found to be under-exposed.

I find it a good plan to filter the developer through clean cotton wool placed in a glass funnel kept for this purpose only, after developing every plate or two, as all marks or spots are thus avoided.—I am, yours, &c.,

Fleet, Hants, November 14, 1892. J. T. Hackett.

To the Editor.

Sir,—Amidol or not amidol? that is the question.

It comes to us boomed by men in the first rank of photographers. Side by side in the photographic journals are letters, some crying, "This is the El Dorado of developers;" others saying, "It is 'stuff,' which it is only waste of time and money to mess about with."

Strange as it may seem, I quite believe that the writers of these widely differing reports have written in all fairness and sincerity, and that they do but report their own experiences. My own experiments compel me to regard it as far and away the best-known developer for snap-shot work. I am quite sure that it will give a printable negative from an exposure which no other known developer can do. I make this assertion from careful and sufficient tests.

At the same time, I have used it with the most deplorable results. Here is, I think, the key to the riddle. It suits some makes of plates and is useless for other brands. This explains why some experimentalists praise it and others condemn it.

I have suggested this to Messrs. Fuerst Brothers (the London agents), and recommended them to issue with their "instructions for use," a list of the makers whose plates are suited to this developer.

I do not think it a good all-round developer (this may be because I do not fully know its capabilities). I should not use it for studio or tripod work, but I should use no other for snap-shot work.

This is saying more in its favour than appears on the surface, because, I think, the hand is ousting the tripod, and the enlarging apparatus supplanting gigantic cameras, lenses, and plates, together with the gigantic cost of purchase and working them. If the hand camera be not the only one used, in the open, in a not distant future, I believe it will be the principal one, and the only really necessary one—with quick plates and amidol.—I am, yours, &c., BART. ROUS.

Nov. 15, 1892.

To the EDITOR.

SIR,—You spoke so highly lately of amidol as the most likely to supersede pyro that I concluded to try it, and now I am more conservative than ever.

I found in the first trial that the picture was rather flat when developed with amidol, but thought it was due to my exposure. I have since found that this was not the reason. The developed image is too transparent in the high lights to give sufficient contrasts, which means that the resulting colour of the film in the negative is not intense enough. Yet I thought I might be able to overcome this trouble with a little experience, the ready-made and long-keeping, non-staining solution always ready for use being unmistakably a great convenience.

Bad weather made me stop my trials for about two weeks, when I received your No. 1697 of THE BRITISH JOURNAL OF PHOTOGRAPHY, and read therein "W. S. P's" and "Othello's" troubles. I at once made a new trial with my two weeks' old solution. Made a positive by contact and developed with old amidol, and got no trace of an image; washed the plate thoroughly and developed same with pyro, and got a fine positive. No more amidol for me, so far, at least, until it gives all what it has promised.—I am, yours, &c., A. LEVY.

4, *Avenue Pinel, Asnières (Seine), November* 11, 1892.

P.S.—Referring to Mr. J. K. Tulloch, M.B.'s paper in same number, you can see what amateurs have come to by reading all the laudatory notes published about them. Their head is continuously swelling, and if there is no stop the doctors will have to be called. In this letter you will find that *it is a well-known fact that every invention and discovery in photography has been from the unselfish and enthusiastic amateur.* This little sentence is unfortunately followed by: *It is easy for the amateur to hurry his little inventions off to the journals; it will take no bite out of his mouth.*

Now, there is one small item which has never been well cleared up. Who is it that fills up your column of "Recent Patents," amateurs or professionals? Which? If amateurs, their hurrying to the journals is sometimes checked midways by the Patent Office. If the much-despised professional, then *every invention, &c.* (see above), *is not* from amateurs only. Let us have some fairness, please.

MR. BHEDWAR'S PICTURES.

To the EDITOR.

SIR,—In a contemporary, of whose existence you are perhaps unaware, I, as Mr. Bhedwar's exhibition agent, explained a few weeks ago why his interesting "Naver" pictures did not appear at Pall Mall; but, since you express some anxiety to know how it happened, I will explain again. Mr. Bhedwar, a month or two back, resigned his membership of the Photographic Society of Great Britain, although, being a foreign member, he had nothing to pay for the privilege. He also, when forwarding his pictures, instructed me not to send them to Pall Mall. From these facts, Mr. Bhedwar being an inveterate exhibitor, the only possible conclusion appears that he, in common with some other artist photographers, lacks confidence in the management of the Photographic Society of Great Britain's show. It is possible you may have noted that a feeling of reluctance to submit their works to the judgment of "scientific experts" has grown among those latter day photographers who are striving to gain higher recognition for the "black art" as a means of artistic expression. —I am, yours, &c., RALPH W. ROBINSON.

Redhill, November 14, 1892.

[It is not a little singular that although, according to Mr. R. W. Robinson, Mr. Bhedwar, when forwarding his pictures (we suppose early in September), gave instructions that they were not to be sent to Pall Mall, our correspondent, the author of the article "An Indian Studio," in an interview with Mr. Bhedwar early in October, should have gathered the information which led him to believe that the pictures were at the Exhibition. As Mr. Ralph Robinson appears, from his amusing statement that Mr. Bhedwar, at a distance of many thousands of miles, lacks confidence in the management of the Society, to be the keeper of that gentleman's conscience, perhaps he will make a still further contribution to this discussion by giving us a theory accounting for the fact that our Indian correspondent's information conflicts with Mr. Robinson's. The concluding sneer as to the "judgment of scientific experts" reminds us of the story of the animal that bit the hand which had succoured it in pain.—ED.]

PROFESSIONAL PHOTOGRAPHY.

To the EDITOR.

SIR,—There are times in the eventful life of a professional photographer when his tranquil soul is stirred to the deepest depths. It may be that it is caused by the advent of a baby entering his sanctuary, or a Scotch collie panting for breath, or similar such emotional occurrences; but the photographer of to-day could certainly not remain callous if he had witnessed the group of about thirty earnest and, as the chairman justly remarked, representative men meeting in solemn conclave to discuss the present status of the photographic profession. Never before in the annals of photography was it more necessary that this should be done, or the need for strong union, more apparent than at the present time. What wonder can it be, then, that one feels interested in, nay, sanguine about, the eventual success of the body meeting on Lord Mayor's Day at Anderton's Hotel? But, also, where were those who should form additional and important links in the chain of strength about to be formed then? Only five London members were present. It was evident, however, that the others had not remained away from apathy. Photographers, owing to the quick, if not easy, production their art is capable of, wanted, perhaps, to see some tangible result of the new Society's doings. Oh, that they could have been present, and have seen the herculean task that the little band of determined men had before them! If they could but perceive that, by their absence, they delay the dawn of a brighter future for the profession generally, they would come in numbers to counsel and help. Now, sir, I firmly believe that it was principally owing to the difficulty of conveying in writing an adequate idea of the useful work the Association is doing that more were not present. I am also aware, Mr. Editor, that I can fully rely on the intense interest you have always manifested in the profession; therefore I beg to be allowed to offer a few remarks on the subject, which I make in the hope that it may induce an increased membership for the Association. I will, in virtue of a resolution passed at that meeting, do myself the honour of calling upon such of the principal members of the profession as the limited time at my disposal will permit.

It must necessarily be premature to expect the immediate carrying out of all those schemes which are known to be needed, however they are constantly held in view, but I can assure you there exists the nucleus of a society which only requires a sufficient number of additional members to make it similarly powerful with the Pharmaceutical Society, Mr. Martin, a member of which, being present, treated the National Union of, &c., to an explanation of their methods in an able speech. He described their gigantic success as being due to brotherly co-operation and casting aside those differences which are the result of great competition. Well, we must join hand in hand. Such names as grace the Council—some of the best professional men—are a sure guarantee that nothing will be left undone to uphold the dignity of a profession which is none the less elevated for being surrounded in their own rank by elements which threaten its very existence.

Can anything be more inspiring than the thought of belonging to a union—the National Union of Professional Photographers—the membership of which alone will be a guarantee of respectability and standing, for it is essentially constituted by some of the foremost men of the profession to combat all that is derogatory to the well-being of the craft?

Will your professional readers who are concerned hold aloof any longer?

Will they not avail themselves of the splendid chance of proclaiming to a suspicious world that they do not stoop to underselling their neighbour, that they do not sell bromide prints for platinotype, &c.?

It may be said that in spite of the initial difficulty of the undertaking, in spite of some discouraging facts, it stands there as the early evolution of a rock, to which, some day, the profession of the future will have to cling for its existence perhaps. Already the signs are not wanting that its diplomas, when it feels strong enough to issue them will be prized by friends and feared by enemies. I imagine the unjustly treated plaintiff or defendant in a photographic law suit, aided in word and deed by their own legal representative. I see the employer and apprentice protected, and witness in spirit the triumph of the system of apprenticeship over the technical schools which, however, may become valuable in their co-operation. In fine the profession will be purified, although the cheap article will always be in demand, and the supply forthcoming. The art production will be valued. Honest labour is worthy of its pay, but skill requires additional reward, which should never depend upon the caprices of the money market. Having come thus far with my remarks, your valuable JOURNAL arrived, and in glancing over it I alighted upon an article by Mr. Tulloch, M.A., which, bearing on the same question certainly requires an answer, for which reason I pray you, Mr. Editor, to to bear with me a little longer.

The introductory affirmation by this gentleman, that he counts many professional friends, I doubt not, but the tone of the letter gives another illustration of the truth of the remark, "Save me from my friends!" I must say candidly, that I do not quite admire the style of Mr. Tulloch's article, and think that his arguments are decidedly weak in many parts. Without going deeply into the matter I will traverse a few; that there are grievances to be remedied is simply proved by the existence of the National Union of Professional Photographers, that that body, the mouthpiece of the profession so to speak, has no animosity against any *bonâ fide* amateur, was evident to all who had the privilege of listening to the excellent address by the Chairman, Mr. Fall, of Baker-street; moreover, I am convinced that most professional photographers worthy of the name would hold out a helping hand to any considerate amateur. The abolition of the strained relations alluded to by him is the aim of the

society before mentioned. Their cause, however, is narrowed to the limits of the questionable amateur on the one hand, and the unscrupulous professional on the other. Let me mention one irrefutable fact, showing that professional photography, contrary to Mr. Tulloch's opinion, must be somewhat on the decline. The facilities of the pastime of photography are responsible for attracting one or another member of most respectable pretty well or even moderately well to do families. These, generally the most lively and energetic specimens of humanity (excepting perhaps the Salvation Army), practise on their own relatives, and on those remaining families with whom they are acquainted, and who have not the good fortune to count an amateur amongst their number, to such an extent, that they generally manage to get at least one good negative. This naturally cools the ardour of being photographed; they are often satisfied with their productions, and thus the professional either loses them altogether or sees very little of them.

An all-wise Providence has certainly left us a good many of the aged and infirm, the tiny little squaller beyond the amateur's reach or patience, &c.; but a goodly portion of the out-of-door trade is appropriated by the amateur, and I know many photographers besides myself (in fact, I do not think I am far wrong in asserting most professionals) who have often met with the threat held out by some secretary or delegate of a club, that if the professional did not consent to a lower rate, one of their number would do the work—in fact, had offered it. Need I go further?

It is amusing to find it continually recurring by speakers and writers (Mr. Tulloch in present instance) that they seem to feast on the fact that all inventions or improvements in photography were effected by the amateur.

Granting for the sake of argument that this is the case, it must be obvious that it is rather childish to try to profit by that, considering the extremely small number of those who have patience, perseverance, and brain power enough to invent anything. But we know it has been shown again and again that professionals have a fair share in the work. As far as practical knowledge is concerned, it lies in the nature of things that the bulk of first-class professional photographers are bound to have a better knowledge of photography than the amateur. At our societies, especially the young ones, professional photographers are often principal spokesmen; and are not the rest of those who ever say much that is valuable, with few exceptions, essentially professionals of a kindred nature, such as doctors, chemists, opticians, professors, &c.?

Mr. Tulloch makes another observation which is especially weak in argument.

"Does he (the professional) not sometimes encroach on the picture framer?" etc. "And it is just this class of men who cry out against the amateur."

Great Scott! (excuse the expression Mr. Editor, I think I have borrowed it from a distinguished amateur, Mr. Pringle). What professional photographer will make his own frames? If he does so, he is more likely to employ a professional frame maker as assistant.

Surely Mr. Tulloch does not, it appears to me, know much about the professional end. I really cannot refrain from making use of his own weapon, and say, "And it is just this class of man who talks nonsense about the profession. Mr. Tulloch evidently means well, but he should be more careful in making statements on matters with which he appears to be only partially informed.

I feel sure that all first-class photographers indignantly repudiate the idea that there is the slightest *animus* against the *bonâ fide* amateur, unless it be caused by those who feel that they are so far above the poor professional in the social scale, that they look upon him in the light of a professional boxer, tinker, or such like.—I am, yours etc., J. HUSBAT.

November 14, 1892.

PHOTOGRAPHIC CLUB.—November 23, *Flashlight Photography*. 30, Monthly Lantern Meeting.

WEST LONDON PHOTOGRAPHIC SOCIETY.—November 22, *A Discourse on Art*, &c., by Mr. J. C. Dollman.

PUTNEY PHOTOGRAPHIC SOCIETY.—November 21, *Bromide Enlargements*, by the Eastman Company. December 5, *Work with a Hand Camera*, by Mr. A. R. Dresser.

ALDENHAM INSTITUTE CAMERA CLUB.—Next meeting, Tuesday, November 22. Subject: continuation of lecture by Mr. Allan Hair on *The Human Eye as a Camera Obscura*.

WE are extremely happy to learn that Mr. Hollyer's benefit day, on Saturday last, realised the handsome sum of 12*l.* 12*s.* 6*d.* for the funds of the Photographers' Benevolent Association.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday, November 22, to be held at 50, Great Russell-street, at 8 p.m. Subject—*The Preparation of Photographs for Exhibition*, and *A Demonstration of Flashlight Portraiture on Dry Ferrotype Plates*.

FIRE AT THE STEREOSCOPIC CO'S.—A fire, which is officially ascribed to the overheating of an electric wire, occurred early on Wednesday morning at 106 and 108, Regent-street, upon the premises of the London Stereoscopic and Photographic Company. The shop window was in flames when the firemen from Great Marlborough-street were called up, and a hydrant had to be set to work to subdue the outbreak. The firemen prevented the destruction of the shop, but that and the house of thirteen rooms and the contents were seriously damaged.

THE Annual Dinner of the Photographic Club was held on Wednesday evening last, under the presidency of Mr. William Bedford. The toast of the Club was acknowledged by Mr. F. A. Bridge; other toasts being "Kindred Societies;" "The Chairman;" and "The Photographic Press," acknowledged by Mr. Thomas Bedding (THE BRITISH JOURNAL OF PHOTOGRAPHY) and Mr. H. Snowden Ward; and the "Visitors" (spoken to by Mr. H. Smart and Mr. W. J. Belton). A pleasant evening was passed, although the attendance was somewhat smaller than usual on account of the unfavourable weather.

THE Exhibition in Pall Mall, which closed last week, may be considered as the most successful the Society has ever held. The number of visitors to the Gallery, from September 24 to Thursday Nov. 10, reached a total of 10,361, the lantern evenings especially showing a very decided increase. On Nov. 9, the last lantern display, brought over 300 visitors together, and the slides shown by Captain Abney, Mr. F. P. Cembrano, jun., and Mr. B. G. Wilkinson, jun., were much appreciated. Amongst others, the President exhibited a slide of a flying bullet, by Professor Mach, the different features of which he pointed out. One by Mr. Cembrano, showing a very extraordinary combination, brought about by the same plate having accidentally received two exposures, and Mr. Wilkinson's *Sunset Calm*, were received with great applause.

THE South London Photographic Society will hold their annual exhibition and competition on the 24–26 November, at the Peckham Public Hall, Peckham, S.E. There are eight classes, six members' and two open to members of South Metropolitan photographic societies. Silver and bronze medals are offered in each of the latter. Messrs. F. P. Cembrano, jun., A. Pringle, and A. H. Hinton have consented to act as judges. A large number of entries are expected. The latest novelties and appliances in photographic apparatus will be exhibited by Messrs. Adams, Burr, Hy. Crouch, Ltd., Dolland, Powell & Sons, Percy Lund & Co., Moody & Cattams, Noakes, Photographic Artists' Supply Stores, Powell, Rice, Slater, Wormald, and others. Demonstrations will be given at intervals of the working of photographic processes by the Platinotype Company and others. Lantern displays and instrumental music each evening. On Saturday, at eight p.m., a concert by talented artistes will be given, followed by Mr. H. G. Banks's popular lantern entertainment, *A Tour in the Channel Islands*, and a series of dioramic effects by the triple lantern by Mr. Leonard Greaves. Particulars of space for exhibits can be had on application to the Hon. Secretary, Chas. H. Oakden, 51, Melbourne-grove, East Dulwich, S.E.

HACKNEY PHOTOGRAPHIC SOCIETY'S AWARD LIST.—Members' Work: Class A, for any picture taken *since* last exhibition, except animals, portraiture, and *genre*.—Mr. Houghton's prize, Mr. Carpenter, Nos. 1 and 2; Mr. Potter's prize, Mr. W. L. Barker, No. 65; silver medal, Mr. Samuel J. Beckett, No. 16; bronze medal, no award. Class B, for any picture taken since membership, but *prior* to last exhibition, except animals, portraiture, and *genre*.—Silver medal, Mr. S. H. Barton, No. 97; bronze medal, Mr. W. Wesson, No. 106. Class C, for any picture taken at a club outing *since* the last exhibition.—Silver medal, Mr. Hensler, No. 113; bronze medal, Mr. J. O. Grant, No. 136. Class D, for portraiture and *genre*.—Silver medal, Mr. G. Hankins, No. 193; bronze medal, Mr. Samuel J. Beckett, No 13. Class E, for set of four lantern slides taken *since* last exhibition (still life excluded). Given by Proprietors of *Hand Camera and Lantern Review*.—Silver medal, Mr. W. P. Dando, No. 205; bronze medal, Mr. Samuel J. Beckett, No. 203. Class F, for set of six hand-camera pictures. Given by Proprietors of *Photography*.—Silver medal, Mr. W. P. Dando, No. 220; bronze medal, Mr. G. Hankins, No. 230. Class G, for best picture of animal life. Given by Proprietors of *Photography*.—Silver medal, Mr. J. O. Grant, No. 238; bronze medal, Mr. S. H. Barton, No. 239. Class H, for set of six stereoscopic slides taken *since* last exhibition.—Silver medal, Mr. T. Horne Redwood, No. 217; bronze medal, Mr. W. L. Barker, No. 249. Open Classes. Class I, for set of six lantern slides.—Silver medal, Mr. J. E. Austin, No. 256; bronze medal, Mr. A. Brooker, No. 262; also an extra bronze medal to Mr. Carpenter, for No. 250. Class J, for set of six stereoscopic slides. The silver medal given by Mr. Houghton withheld; bronze medal, Mr. J. H. Spencer, No. 265. Class K, for any picture except portraiture and *genre*.—Three silver medals of equal value, Mr. F. S. Scott, No. 276; Mr. C. B. Lewis, No. 335; Mr. J. E. Austin, No. 291. Class L, for portraiture and *genre*.—Silver medal withheld, and three bronze medals awarded, Mr. Lyddell Sawyer, No. 314; Mr. S. N. Bhedwar, No. 361; Mr. R. Terras, No. 311.

Answers to Correspondents.

PLATT AND WHITE.—Price list received.

ALEX. DONALD.—Thanks for the information.

BEGINNER.—The markings on the prints are due to imperfect fixation.

PAINTER.—We must decline to offer an opinion unless we heard both sides.

A. HEILMAN.—You can procure the albo-carbon attachment by ordering it from a lamp-dealer.

E. D. (York).—We imagine that you would get the articles better made in Leeds than anywhere else.

INQUIRER.—We are sending your letter to the firm in question, and shall learn what they think of the matter.

CHARLES HOARE.—The specimens (which have been returned to you) are excellent in posing, lighting, and retouching.

OPTICAL (Paignton).—Of the two lantern screens, one being opaque and the other transparent, the former will give a much more brilliant image than the other.

W. R. HUTCHINSON.—Some articles on the subject of lens-grinding have been recently published in the *English Mechanic*. These, we imagine, will give the information required.

FLORENCE says: "Will you give me some idea how photographic magic-lantern slides are coloured, or what book I can get on the subject?"—See an article on the subject by Mr. E. Dunmore at p. 10 of the LANTERN SUPPLEMENT for November.

H. G. M. CONYBEARE.—1. One combination of the lantern objective (the front one reversed) may be used with a fair measure of success to get a long focus. 2. The ten-feet disc with the single combination will not be so well illuminated as when the complete combination is employed.

T. C. W.—It is rather a sweeping assertion to make, "that all bromide enlargements fade." Those you have were evidently carelessly produced, or they would not have become yellow in three months. There is no question as to the stability of carbon pictures under ordinary conditions.

J. T. ROBINSON says: "If I were to adopt the name of planotype to all photographs, do you think it would be considered an infringement upon platinotype?"—Whether it would be an infringement or not, we should think it would be better not to employ a title likely to be misleading.

F. S. GREEN asks: "Can you tell me where to find information on the methods of testing the sensitiveness of dry plates; the methods of Hurter & Driffield and others?"—Messrs. Hurter & Driffield's method is published in a pamphlet which may be obtained of the Society of Chemical Industry, London.

D. SULIVAN.—If the photographer named has only obtained a photograph of Her Majesty, as she was driving through the country, with a hand camera, he is certainly not entitled to style himself photographer to the Queen and put up the royal arms on his shop-front. Not only is he not entitled to do this, but he renders himself liable to a heavy penalty for his act.

ARCHD. STEVENSON.—The two halves of the condensers described, each four inches and five inches respectively, will make a combination quite suited for your purpose. Let the mount be so constructed as to enable you by one or two trials to determine the best distance for the separation of the lenses, adhering to the general system shown in your drawing, which is substantially correct.

A. W. S.—The only way to deal with the damaged negative is to make a transparency from it, and then touch out the damage as well as you can; then, from that, make a fresh negative, and repair carefully what could not be made good in the transparency. By this means, in skilful hands, a negative can be reproduced that will yield prints which will require little or no touching up.

JOHN WORSNOP says: "Would you give me the addresses of one or two of the best Continental collotype printing firms? Also state if this class of work can be done as well and as cheaply in England."—Messrs. Waterlow, Messrs. Morgan & Kidd, The London Stereoscopic Company, all undertake collotype work, and execute it quite as well and probably as cheaply as Continental firms.

S. TOPPING says: "There are so many formulæ' published for collotype, will you please tell me which is best?"—All the formulæ, though often materially different, that have appeared in our columns, are good. In collotype more depends upon conditions than mere formulæ. It is better to adapt conditions to formulæ than formulæ to conditions; or, better still, adapt the one to the other. This is what practical workers do.

JOHN GASCOINE.—"Will you kindly tell me how to make ink for drawing over a photograph, and also the preparation to dip it into to take away the appearance of a photograph and leave the ink drawing?"—Take an untoned silver print, made the drawing upon it, and then immerse the picture in a solution of bichloride of mercury until the image disappears. The ink must be one that is unaffected by water. Brunswick black thinned with turpentine or "litho chalk" will answer.

A. Z. writes: "A traveller called on me some time back soliciting orders for prints, which he said he would supply on sale or return. I ordered some on these terms, at his earnest solicitation. They came, and were invoiced to me. Now the people have sent an account for the whole of the prints, and demand payment, although I have not sold half a dozen. How should I act?"—If the prints were supplied on the terms named, return those unsold, with the money for those disposed of.

TURNSTILE writes: "I had to copy a bas-relief, and my customer has rejected the picture I have made, saying that it is not good, as it does not fairly show the amount of relief there is in the original. The picture is perfectly sharp all over, and shows all the marks—even of the chisel. What more can I do?"—Mere sharpness is not all that is necessary in such a case; there must be sufficient chiaroscuro to give a correct representation of the original. Try the effect of lighting the work with a strong side-light, and give such an exposure as will avoid black shadows.

STUDIO.—The sketch shows a very good studio, but it is one better suited for single figures than for the general run of professional work, which often includes large groups. We should prefer ourselves a studio with the ordinary side or top light. For the proportions proposed to be adopted twelve feet of glass, side and top, will be ample. Five feet at the top (background end) should be opaque; but it will be convenient to have the side glazed to about three feet at that end for certain effects when required. About forty-five degrees is a good angle for the roof.

INJURED writes: "Some little time back I took the portrait of a very popular local clergyman. The newspaper published in the town, since his death, has given as an illustration his portrait roughly sketched from my picture, which I made copyright when it was first taken. The paper says the cut was made from my picture, but they did not ask my permission to use it. Can I proceed against them for damages?"—Yes; certainly you can proceed, but we doubt very much, under the circumstances, if you will recover anything beyond mere nominal damages, inasmuch as, we imagine, you will have a difficulty in proving that you have sustained any. We should think the picture appearing with your name appended was a good advertisement for you, and increased the sale of your photograph rather than otherwise.

ARTHUR BLAKEMORE writes: "Would you kindly tell me how to mix the distemper for painting backgrounds, and what colours to use? Also, can you refer me to any firm where collodio-chloride paper is obtainable?"—Distemper is made by mixing dry colours with water, and then adding sufficient melted "double size" to cause the mixture to form a thin tremulous jelly when cold. In this state it is to be applied. Any colour can be used, according to taste. Whiting and lamp black will do very well for a grey background. A little Venetian red may be added to give a warm tone. Collodio-chloride paper may be obtained through most dealers in photographic materials.

C. R. A. writes as follows: "Will you kindly answer the following questions? Can any one copy a view in England that is copyrighted and manufactured only in the United States? To protect, must the subject be registered here on the same date that it is copyrighted in America? Can we register views here which are manufactured in America, but which are not copyrighted there? According to American copyright law, negatives must be copyrighted before one print is offered for sale to the public. Is the law the same in England? If not, can an American manufacturers have subjects which are not copyrighted or protected in his own country registered by himself or his agent in this country, and so receive protection in Great Britain? To explain, copies of an American artist's views are now being manufactured in America. This cannot be stopped according to American law, as they have been sold for some time without being copyrighted. Now, if these copied views are shipped into this country, can the original photographer's agent, by getting original subjects registered here, stop the sale of these copies? Another question. We notice the publication of the registration of certain photographs in THE BRITISH JOURNAL OF PHOTOGRAPHY. Does your JOURNAL publish each week every photograph of any description which has been registered during the previous week? Can you also give us the address of the firm who had control of the photographic privilege in the Paris Exposition?"—We are not sufficiently versed in the International Copyright law as regards America, which differs from that of other countries, to give an authoritative opinion. We should advise that a solicitor, who makes a speciality of copyright law, be consulted. The list of pictures made copyright which appear in our columns are only those our publishers have registered for our correspondents. We cannot supply the information with regard to the Paris Exhibition. Perhaps some of our readers may be sufficiently conversant with Anglo-American copyright to reply to our correspondent.

REPLY TO F♯.

A THING of beauty *is* a joy for ever—
So Keats has said, and so we all agree—
But I should think, F♯, that I could never
Decide what's beautiful for you, or you for me.

Nature looks not the same to every creature,
And those new pictures truthfully convey
In each soft line and gentle, hazy feature,
The dreamy stillness of a summer's day.

We might compare the rival styles to music—
'Tis very much the same, it seems to me;
The *major* long has reigned—then let us welcome
Those charming studies in the *minor* key.

Pray, look again! They are not shapeless masses;
Your condemnation's scarcely just, though smart:
Your hand—come, ere the fitting moment passes—
Three cheers for our good President—and Art.

THE PHOTOGRAPHIC BLUNDER AT THE WORLD'S FAIR.

Probably those who framed the regulation regarding the admission of cameras to the Chicago Exhibition and the exclusion of stereoscopic cameras had some good reason for the latter element in their decision, but they could scarcely have realised that the obtaining of pictures of the excluded class is not by any means confined to operating with a properly constituted stereoscopic or binocular camera.

When it is considered that a photograph of this kind is nothing else than a duplication of any subject, each taken from a point of view a few inches to the side of the other, it will be apparent with what facility this may be done with a single camera, by taking first one view and then another, previously shifting the camera a little to one side before exposing for the second picture. This, we may observe, was the method adopted for obtaining many of the early stereoscopic scenes of still life. Nay, as we have many times proved, the same end may be secured by the mere rotation of the camera on the stand between the exposures, the only condition for obtaining the necessary dissimilarity being to have the nut in which the screw of the camera stand engages as near as possible to the rear of the camera. A very slight degree of rotation suffices to displace the position of the lens when this system is adopted. True, the amount of the subject on the plate will differ, owing to the central object in one being a little to one side in the other, but this is made right in the trimming of the prints.

Although moving figures or active life cannot be taken by any of the methods just described, yet can this be obtained by two persons having hand cameras and acting in concert. The conditions for taking instantaneous stereoscopic pictures are by no means difficult of attainment. First of all, their cameras must be similar as regards focus of lens, aperture in stop, and rapidity of shutter. They must stand very closely together, side by side. If one possesses the ability to hold his camera under his left arm, while the other holds *his* under his right, an approximation of the instruments will be secured sufficient to give excellent stereoscopic relief in a binocular picture composed of the two photographs thus obtained. A precaution must be taken to avoid having any figures or objects too close to the cameras in this case, else may the relief be exaggerated. It is also necessary that some definite object be fixed upon to be in the centre of the finder, and that both exposures be made simultaneously. For this latter purpose the old-fashioned "once—twice—thrice" will suffice.

We are quite unaware of the reasons by which the directors of the World's Fair have been actuated in making what seems to us at present an unwise inhibition of the practice of photography in a direction altogether contrary to the spirit of the age. But, seeing that they have done so, and that the restraint is, as we understand it, confined to *stereoscopic* cameras, while single or monocular cameras do not fall under the ban, we cannot perceive that violence is done to any principle of ethics by those artists who, while adhering literally and strictly to the conditions of entry imposed upon photographers and pay the sum *per diem* which they are charged, may prefer to use their instruments as they choose, or in some such way as we have here indicated.

Had it been hand cameras that were debarred admission, one might, in view of the displeasing, if not aggressive and offensive, uses to which they are frequently put, readily be inclined to acquiesce, nay, give cordial assent to the interdiction; but upon what principle binocular cameras have been singled out for exclusion we quite fail to understand.

BACKGROUNDS.

A communication recently received from a professional photographer as to a method of storing backgrounds seems to us of so practical a nature as to be worthy of especial note. *En passant* it may be said that, for the last decade or longer, the art of painting backgrounds for photographic use has been brought to a high state of perfection, and there is nothing invidious in stating that it is to Seavey, of New York, that what is in effect a revolution is due. Every one remembers the mechanical style of painting for this purpose that was contemporaneous with the introduction of the *carte-de-visite*. The artistic instincts of many good men so rebelled against it that a reaction set in, and in many studios this particular accessory was conspicuous by its absence. Then the new and really artistic style was introduced, and copied in detail, and finally a new class of painters took up the work, till it became possible to procure every variety of subject with every style of lighting, executed in a manner that would, in most cases, commend itself to the most captious of critics. When, however, a photographer became possessed of a number of these paintings, the question of how to utilise them in the readiest manner became a pressing consideration. One or two could be hung in the usual fashion of theatrical drop-scenes, but with a dozen or so some method had to be devised to enable any particular one to be brought into use with the least loss of time and expenditure of labour. To have a row of them one in front of the other was quickly seen to be open to the objection of producing shadows on the upper portions, a matter, perhaps, of little moment with interiors, but productive of very grotesque effects when an outdoor scene was required. A line of shadow on the

clouds, for instance, was utterly unpermissible with the least exacting photographer. To avoid this, two separate modes of arrangement were adopted.

In one a special background frame was invented, which allowed any special scene required to be brought to the upper portion of the framework and run into position, free from shadow from top to bottom.

The other method consisted in stretching the painting upon a suitably strengthened framework, and keeping a store of these framed backgrounds in the most convenient manner possible. The fortunate possessors of studios of large dimensions had no trouble in the matter, as a considerable number could be placed up and down the studio without being in the way. An excellent manner of working these mounted pictures consisted in stretching them one on each side of the framework, and then supporting them on projecting feet, with struts to give them rigidity, and rolling castors fastened below the feet to render them easily shifted as occasion required. It is with regard to this particular arrangement that the correspondent we refer to sends us information. He has a number of such frames, made in sets of gradually increasing widths between the feet, so that they fit within one another like nests of boxes. But even then, taking the projection of each foot to be, say, eighteen inches, it is evident that half a dozen such frameworks must occupy a space nine or ten feet from back to front, and so by that extent must the available length of the studio be reduced. In some studios, of course, this reduction of space would be a matter of indifference; but it may be safely asserted that the majority of studios would be seriously inconvenienced by being thus shorn of their longitudinal dimensions. The suggested method, then, is for the benefit of those who have adopted this plan of movable screens, and find a growing inconvenience from their multiplication.

The improved way of working is twofold. First, frameworks of rather lighter build are used for additional background pictures, and these are suspended by suitable supports from the upper part of the original frame. Each of such frames may then be made to bear a stretcher or frame, with its two paintings on each face, and thus one set of castors would carry six paintings in three pairs. Any one of them could immediately be utilised either by this temporary removal of the loose frame, which would thus uncover the picture it hid, or be set up on either of its two sides selected, and then rehung.

The other method is to alter the arrangement of the supporting feet. One face of the framework is to be made free of projection from top to bottom, and the castors removed so as just to project, and only so, beyond the level of the face. The stability of the whole would then be considerably lessened. There would be danger of the whole falling over at some untoward moment by the slightest disturbance of its equilibrium. This is to be remedied, first, by so packing the last-named castors as to give the whole frame a permanent tilt in the direction of the feet which are not removed, and the tendency to equipoise is to be still further augmented by the attachment of a weight to the foremost portion of the feet, which would thus act as a lever to arrest any tendency of the framework to topple over. The plan commends itself by its simplicity and evident practicability. If our description be understood, it will be seen that the possessor of half a dozen such frameworks, instead of reducing the length of his room by the three yards or more, can, if they are of "nested" shapes, store them close against one another, and readily store that number in a space of about half a yard. We had intended to make some reference to the use of the scenes, but must defer that branch of our subject to a future occasion.

AMIDOL.

The published experiences of those who have tried this new developer are of a curiously contradictory nature. Some workers hail it in terms which imply that for negatives it possesses all the elasticity of power of pyro with the added advantages of greater rapidity and cleanliness of action; while, at the same time, for positives on paper or glass some find that it is a worthy rival to ferrous oxalate on the one hand, and the various developers which are used for lantern slides and transparencies on the other. Contrasted with these favourable estimates, however, we find several complaints which go far to dispute its value for negative purposes, although it is true little, if any, objection has so far been taken to it for transparency and paper pictures.

It will be remembered that some months ago we were the first to discuss the properties of the new developer, from an experience derived from several trials of it. Subsequent experiments with it have not materially altered the opinion we then gave, and this notwithstanding the various drawbacks which others have found in using it. Summarising these latter, they appear to be chiefly that the solution used according to the original formula, and in great dilution even down to 1 : 10, has a strong tendency to produce surface fog; that its command over detail is inferior to that of pyro; that it yields density with difficulty; that either in plain solution or with sulphite it quickly loses developing strength, a feature which seems to expand in the ratio as it were of a concurrent discolouration.

In our own experiments which we have recently confirmed, we have found that the invariable employment of a grain of bromide to the ounce of developer has the effect of counteracting the veil in properly exposed plates, and herein we are inclined to think lies one secret of the successful employment of amidol. Bromide, in fact, is indispensable in normal exposures, and should be increased or decreased in accordance with the disposition to over or under-expose. Naturally this slows development, the too rapid action of which we have also clearly proved to our own satisfaction is responsible for the frequent lack of density complained of. The use of bromide both obviates veil, and ensures density with amidol.

As regards detail, we are yet unable to ascertain that it has any superiority to pyro; but, on the other hand, it is not appreciably, inferior. We at present hesitate to definitively assign amidol its true place, inasmuch as it is still very little understood for negative work. For transparencies it works clearly and brightly, and the tones on glass it yields with full exposure, are characterised by an almost wet collodion-like quality. This brings us to another important objection to it, namely, its lack of keeping properties in solution.

As a matter of fact, we have found amidol in solution most puzzling in its keeping qualities. With boiled, distilled, and ordinary tap water, curiously enough, and with the same sample of sulphite, it has, in the course of a few days, exhibited in our hands different degrees of discolouration and developing power. But difficulties on this score need not be tolerated if one takes advantage of its ready solubility and uses it dry, as pyro was wont to be used formerly. All then there would be necessary to provide would be the stock solution of sulphite, in which the amidol might be dissolved as required. This, indeed, is the plan we have ourselves adopted.

From our own experience, we suggest that the key to the effective employment of amidol lies in the invariable presence of bromide with it according to circumstances, and its use in the dry state—that is, dissolved as required. We await further results and experiments with much interest.

The Maddox Fund.—It will be seen, from a communication in our last issue from Mr. Andrew Pringle, that the illuminated testimonial to Dr. Maddox has at length been presented to him, a cheque for about 400*l.* having been handed to him several months ago. This week we publish a communication from Mr. Sharp, the Hon. Secretary to the Foreign Fund, by which it will be seen that over 100*l.* was collected abroad, making a total in round numbers of 500*l.* which was raised for Dr. Maddox, whose letter of thanks we also publish this week. Thus ends an incident agreeable and creditable to all concerned in it.

Perfect Negatives.—The subject of the evening at one of the provincial societies was, recently, "What is a perfect negative?" Now, if there is one thing more than another upon which the opinions of photographers differ—and they differ on many—it is on what constitutes a perfect negative, and from what standard it should be judged. At one time the wet-collodion type of negative used to be quoted as the one to be aimed at in the dry plate. That is not the case now, except for special purposes. When this theme is started amongst practical workers, particularly if one or two theorists are present, a pretty smart discussion can generally be relied upon. Here is a hint for many societies.

Photography and the Nansen Polar Expedition.—We understand that Dr. Nansen, who shortly starts on an expedition towards the North Pole, takes the inevitable Kodak with him, presumably with the object of securing, where practicable, a photographic record of his adventurous journeyings. To that end he is also undergoing practical instruction in development, &c., and, with the confidence that seems one of his main traits, reckons upon success in photography as well as in Polar exploration. Some years ago, if we remember aright, Mr. W. J. A. Grant, of Collumpton, Devon, accompanied a private Polar expedition on board the *Wilhelm Barentz*, and succeeded in obtaining photographs of scenes comparatively near the mysterious Pole. A narrative of photographic experiences in such latitudes would doubtless prove instructive as well as entertaining.

Photographic Meetings.—What a marked change there is in the meetings of photographic societies now and in times gone by. The stiff, formal meeting is now a thing of the past, except, perhaps, in one or two societies. The more social character of meetings was, in the first instance, inaugurated by the old South London Photographic Society, and was largely amplified by the Photographic Club. Experience shows that, the more social and less formal the character of the meetings of all photographic societies, the better is the attendance. The tolerance of the "fragrant weed" also, in many instances, conduces to the same end. Smoking concerts are now made a feature of in many societies. Such a thing would, at one period, have been considered *infra dig.* by most, but now they are looked upon by some as the most popular and enjoyable meetings of the year. It is the introduction of the more "free-and-easy" or less formal nature of the meetings that has tended to secure the good attendance at so many of the new societies.

Photographic Trade Unionism.—Judging from the report of the annual meeting of the National Association of Professional Photographers, that body is not so strong as it would wish to be. That the objects of the Society, if they could be carried out, would benefit the profession generally, there can be little question; therefore it is not a little surprising that it receives such scant support from it, seeing that its management is in capable hands. Is not the Association, as we have suggested before, aiming at accomplishing too much? It would certainly be desirable to regulate prices, but we fear this is not to be done. Members of the Association may agree amongst themselves as to a minimum charge, but they cannot govern those who are not members, and the public will go where it suits them best. In a measure it has succeeded in causing a revision of the tariff, to the public, of some enlargers, but not all, it appears. If the Association received universal support, it might do a great deal to the advantage of the profession in many ways, but while its numbers are so restricted its powers are necessarily very circumscribed. At present it is not strong enough to successfully boycott offending wholesale houses, who work alike for amateurs and professionals on similar terms.

Contraction of Gelatine.—At a recent meeting of the Photographic Society of Philadelphia, one of the members said that the strong contractile power of the gelatine employed for some dry plates was so great that it tore away the surface of the glass at the margins of the plates. This experience, we should say, is somewhat exceptional in the States—it certainly would be here—with regard to dry plates. That gelatine has the power to tear away the surface of glass if it be over-dried, every collotype worker is aware. But here the conditions are different from what they are with dry plates With collotype plates the surface of the glass is often ground so that the gelatine has a rough surface to hold to instead of a smooth one. Then, if the film be over-dried, it, in its contraction, tears up the glass in a very curious manner, usually resembling fern leaves. It is on this principle that the decorative glass, known as "crystalline glass," is produced. Different characters of gelatine seem to give different patterns. It may be possible that the strong holding power of the gelatine spoken of in America may be caused by the plates being prepared with a substratum containing a silicate that would give a certain amount of tooth.

DENSITY IN COLLODION EMULSION.

Since the earliest days of the washed-collodion emulsion process more or less difficulty has existed in securing density in the finished product, and numerous have been the expedients put forward to supply the deficiency. These have mostly consisted in the introduction into the emulsion of some kind of organic matter capable of combining with the silver in sensitising to form a more highly organic compound than occurs with the collodion itself.

Lactic and malic acids, as well as lactates and malates, glycocine, and similar substances were amongst those used. Impregnating the collodion with gelatine before converting it into pyroxyline was another method by which it was sought to introduce more highly organic elements, and indeed the changes were rung so completely that scarcely any form of saccharine or gummy matter, or of the organic acids and their salts, escaped trial. Another plan consisted in allowing the collodion or emulsion to remain for some time under the action of free silver in the presence of a considerable excess of mineral acid, usually nitric, though sulphuric acid was also recommended by the late Colonel Stuart Wortley, the function of the acid being to render the action of the silver more caustic and penetrating. In the case of sulphuric acid perhaps another effect was produced, of which notice will be taken further on.

But unfortunately, although many of these plans answered the purpose intended well enough in the case of an unwashed emulsion—that is to say, one that was used for coating the plates before its soluble salts had been removed—it was too frequently found that, in washing the emulsion in bulk to remove the salts, the organic element also disappeared, leaving in most instances a product which, while it might be extremely sensitive and work free from fog, was incapable of yielding printing density. This, apparently, forms a portion of the complaint of "J. R. G.," alluded to in last week's issue.

Some fifteen years ago I hit upon a formula, which I published at the time, by which, combined with the highest degree of sensitiveness, I was able to attain a far greater density than was obtainable even with much slower emulsions; indeed, the trouble now was to avoid over-density. The formula consisted of an emulsion containing an excess of silver as large as five grains to the ounce, held in check as regards its fog-giving propensities by the addition of a

suitable quantity of citric acid. At first sight it might be supposed that such an emulsion owed its properties to the presence of citrate of silver, though I very much doubt whether, even in the emulsion itself, that salt was formed, while it is pretty certain that none could be present after perfect washing.

It has been often pointed out that, although citrate of silver is usually supposed to be insoluble in water, or very slightly so, such is far from being the case, and that on the contrary it is pretty freely soluble. At any rate, if silver nitrate and an alkaline citrate in equivalent proportions be dissolved and mixed, the precipitate just formed is quickly redissolved, while no precipitate at all occurs on the addition of citric acid to nitrate of silver; but, if the latter salt be dissolved in plain collodion, and citric acid added thereto, a dense white emulsion is formed, owing to the insolubility in alcohol and ether of the compound salt formed, whatever it may be. But, curiously enough, if the emulsion be poured on to glass in the ordinary way, it will set and dry perfectly transparent, except, perhaps, for some signs of crystallisation. All trace of citrate of silver is absent; indeed, if it be formed at all, it is redissolved by the nitric acid displaced from the nitrate, and most probably the compound is a citro-nitrate of silver partly soluble in collodion.

It must be perfectly evident that, though this salt may exist in a state of partial solution in the emulsion, it is bound to be removed entirely when the emulsion or film is washed, and that therefore the extra density obtained cannot be due to any citrate of silver left behind. This indeed, if present, would, by reason of its solubility in water, suffer instant reduction, and cause fog the moment a developer was applied, in precisely the same manner as would be the case if excess of silver nitrate were present.

A somewhat similar result occurs if sulphuric acid is added to the emulsion in the presence of excess of silver, as recommended by Colonel Wortley. Although the addition of sulphuric acid to an aqueous solution of the salt causes no precipitate of sulphate of silver, yet, when added to collodion containing silver nitrate, the precipitate does occur, and it was at first supposed to be an organic compound of sulphate of silver and pyroxyline; but I think it is tolerably certain that it is a purely inorganic salt, thrown down by reason of its low degree of solubility in the vehicle. The nitrate is soluble to a considerable extent in collodion, and forms a clear and colourless solution; but, if more than a certain quantity be present, then an emulsion will be formed in the same way by the precipitation of the excess in extremely minute crystals which remain in suspension.

The result as regards density produced by Colonel Wortley's method is similar in character—though less in degree—to that obtained with citric acid and excess of silver, though, as in that case, there can be no sulphate of silver left in the emulsion or film after washing, since that salt is perfectly soluble in water. How, then, do such additions act in modifying the character of the emulsion?

It has struck me that the action is twofold. In the first place we have the organic reaction set up by the soluble silver salt in excess and a further action, of another kind, of the free acid. The latter, as is well known to collodion workers, exercises a tendency in the direction of rendering the collodion thicker or more viscous, and the resulting films more "horny" and tough, as well as impervious to water. This is more particularly the case with citric acid, a comparatively small quantity of which will render an otherwise fluent collodion too thick to spread over the glass. The toughening action is least noticeable with nitric acid, but is very marked with sulphuric.

Now, it seems to me that it is to this last-mentioned action that we mainly owe the increased density obtained, or rather the *retention* of the density after it has been produced by the organic matter. For it is easy to conceive that by rendering the emulsion tougher and less pervious to water we avoid the serious washing away of the important organic element that goes to cause the want of density under ordinary circumstances. In other words, the emulsion enjoys the advantage of excess of silver, while the acid prevents fog, and also arrests the tendency of the emulsion itself to dissolve in washing. The effect is much less marked when the acid used is nitric for the reason I have already mentioned, that the hardening action of the latter acid is much less than either citric or sulphuric.

With these ideas in view, I was led in the early part of the present year to test the matter in connexion with a number of samples of pyroxyline that were utterly unsuited for washed emulsion under ordinary circumstances, and with perfect success so far as density was concerned—this being the great stumbling-block—although I met some curious variations in sensitiveness with different samples of cotton.

My first experiments were made with the old formula containing excess of silver and citric acid, which, in my own way of working, I have almost always found perfectly successful, though I have been told by others that they have failed to work it. There is, perhaps, a liability in the direction of fogginess if too long a period be allowed between sensitising and washing, but otherwise I have never had any trouble with it.

To obviate this slight difficulty, I substituted for the citric acid a soluble citrate, so as to form in the emulsion an undoubted citrate of silver which changes the conditions rather materially. So long as the emulsion remains unwashed the citrate of silver seems to be practically as inert as the bromide, on account of its insolubility in the vehicle in which it remains suspended, but the instant water touches either the emulsion or the film the citrate is started into activity, with the result that the emulsion gets the benefit of the action of free silver during the period of washing, which, as I pointed out in a previous article, is an important point in securing density.

As a variation from this, I added a small quantity of citric acid as well as the alkaline citrate, in order to secure the beneficial action during washing, and this appeared to still further aid density, though not to a very marked degree, the citrate alone proving amply sufficient. The proportions of the citrate employed varied from two to four grains of silver nitrate converted, and, where the acid was employed, I used one grain to the ounce.

It follows, as a matter of course, upon the solubility of the citrate, that the emulsion must be very thoroughly washed to remove it, otherwise the first contact of the developer will cause fog. This point having been attended to, I think "J. R. G.," and such as have any difficulty in getting density, will find their way out of their troubles in the direction I have suggested. W. B. Bolton.

JOTTINGS.

Mr. George R. Sims, a journalist whose comments on passing events invariably possess the merits of common sense, writes thus in the columns of his paper: "My compliments to the Editor of the *Daily Graphic*, and if he could drop those corpses on the seashore I should be very much obliged. A corpse now and then is all very well, but a cold corpse with your breakfast every morning for a week is exceedingly trying to the digestion under the present atmospheric conditions." I have seen some of the sketches "Dagonet" refers to, and very grim and gruesome they are. They represent the bodies flung up by the sea from the wreck of the *Roumania*, and are reproduced by the artist from photographs. I do not know whether the photographs of the bodies were taken under the direction of the Portuguese authorities; but, if they were, it is an outrage on the living and the dead that they have been allowed to pass into the hands of the editor of the *Daily Graphic*. On the other hand, if the photographs were taken by the ubiquitous amateur, and by him passed in to the editor, the sooner public opinion rises to stamp out this debasement of our art to the level of the doings of Burke and Hare, the better it will be for photography, and for public and private decency.

Mr. Ralph Robinson and his friends' revolt against the judgment of "scientific experts" at photographic exhibitions either means that the men who were capable of adjudicating upon the artistic merits of photographs produced before differentiation of focus became popular, are incompetent to exercise a similar discrimination when the latter method of artistic photographic expression is employed, or that in neither case is that judgment to be accepted as reliable. If the latter, will Mr. Robinson and his friends prove the faith that is in them by throwing away or returning all the medals they have received at the hands of scientific experts? Again, supposing the former meaning is intended, why does Mr. Ralph Robinson send Mr. Bhedwar's pictures to Hackney, where the Judges (in addition to himself) were that un-

questioned "scientific expert," Captain Abney, and Colonel Gale, an artist if you like, but above all the most prominent exponent of the highest technique in photography we have? Of course Mr. Robinson did not adjudicate upon pictures of whose exhibitor he was agent; and I therefore ask him if, in the face of his own pronouncement against "scientific experts," he feels justified, on Mr. Bhedwar's behalf, in accepting the medal?

While the photographers are meeting together to discuss their grievances, and to devise remedies for them, the Editor, in a brief append to the letter of a correspondent, gives a piece of advice which should be of great service to a class which I fear is in need of all the assistance that good counsel can afford—a class, moreover, of such a scattered and heterogeneous nature that combination for defensive and ameliorative purposes is practically impossible. I allude to photographers' assistants. The writer of the letter I refer to recounts an old grievance of his class in drawing attention to the reprehensible practice among some photographers of stealing—that is the only term applicable—the specimens submitted to them by assistants seeking employment for them. The Editor says to the assistants, "Write your names and addresses across the pictures." And I would venture to add, say, "This is the work of" So-and-So, and put a date. Such an inscription might prevent theft, and certainly would take it out of the photographer's power to use the specimens for the purposes of deceiving his clients.

So "Talbot Archer" has recommenced his contributions to your contemporary, *Anthony's Bulletin!* Well, well; some journalistic hides are tolerably thick! It is to the lasting credit of British journalism that the only one American photographic publication which joined me in my crusade against "Talbot Archer" is edited by a north countryman, John Nicol, a former contributor to this Journal, a fact which e'en disposes me to forgive him for having politely styled me an "optical ignoramus" in the correspondence columns of the *Beacon*.

Eight photographic exhibitions in the month of November—six of them being held either in London or adjacent thereto—is really too much of a good thing for press and public, although, no doubt, the pot-hunters are in their element. The chief offenders in the clashing are the London photographic societies, to whom I venture to suggest that, in future, an effort be made to avoid overlapping *or* clashing, neither of which are calculated to benefit their exhibitions either in the estimation of the trade, the general body of exhibitors, or those whose duty it is to attend them. Where those exhibitions rely for financial success upon local support, it cannot in the least matter the precise date at which they are held, hence there need in future be no difficulty in arranging "clear dates," so as to obviate the uncomfortable jumble of the last few weeks. Cosmos.

A NEW PHOTO-INTAGLIO PROCESS.

[Journal of the Franklin Institute.]

With the exception, perhaps, of the domain of electricity, there is no other special field wherein the recent advances of science have opened so many avenues of progress and effected such notable changes as in the range of the graphic arts. From the time when, fifty years ago, the earlier researches of Scheele and Seebeck on light-sensitive compounds were first wrought into practical shape by Niepce, Daguerre, and Talbot, the applications of photo-chemistry have increased in number and extent to such a degree that to-day the various processes of photographic reproduction would require a long catalogue to merely name them. Many of these variations, though marked, are unessential; others have proven of scientific interest only, while quite a long list of practical photo-reproductive processes have from time to time been superseded by simpler and more efficient methods.

The new photographic process which I have the pleasure of announcing to the Institute this evening is, as I trust will appear in practice, an effective and greatly simplified method of producing a photographic reproduction in the form of an intaglio engraving. Such engravings, technically known by the French term "photogravure" have been produced for some years past by a variety of photo-chemical processes, the most notable of which are those wherein the result is attained by means of a chrome-gelatine film. The fact that a film of chrome-gelatine becomes insoluble when exposed to light, and remains more or less soluble according to the degree to which light is permitted to act upon it, has been made the basis of a variety of processes for the production of photo-engravings. The gelatine film long served as the most effective means for the production of photo-engravings in relief, and still furnishes the basis for the production of photo-engravings in intaglio. For both purposes the sensitised gelatine film is exposed under a transparent negative or positive, as may be requisite in the subsequent procedure; the unaffected portions and unreduced quantities of the exposed film are either swelled by absorption of a liquid or are dissolved and washed out, and the film then dried. In this condition it may be printed from direct, or it may be used as a mould to produce a reverse in a fusible metal; or it may be covered with an electrolytic surface to receive an electrotype deposit, or it may be moulded in plaster, wax, gutta percha, or other suitable substance, from which, in turn, a reverse can be made by casting or electrotyping. Intaglio photo-engravings have also been produced by a process wherein the varying amounts of reduced silver left in the developed gelatino-bromide plate are made to serve as a corrosive or etching agency on a plate of copper on which the bromide plate is imposed, but in general practice the washed-out gelatine film has thus far proven the most practical means to the desired end.

In all photo-intaglio processes hitherto known or practised, the nature of the plate produced and the end sought to be attained is akin to that which is technically known as a mezzotint or aquatint engraving. The essential feature of such engravings consists of the varying depths to which the design is sunken in the plate, the graduations of depth in the plate corresponding to the gradations of light and shade in the printed impression. The ink being rubbed into the depressions of the design and rubbed off from the surface of the plate, the highest parts of the engraving represent the highest lights of the design, the deepest depressions render the darkest shadows, and the intermediate depths produce the half-tone gradations of the picture.

The difficulties attending the production of photogravure plates with the particular degree of graduation of depth which is requisite for an artistic effect in the printed impression are such that the process is practised only by a few, the skill and experience needed for the work being attained only after a long practice and then in a full measure only by such individuals as possess artistic capacity and training. In only one establishment, and that in Paris, has the work been brought to a high degree of quality, and there, as well as in other workshops, the hand of the skilful retoucher is frequently to be credited with the largest share in the final result.

To free this result as far as possible from the limitations of human handiwork, and to bring it forth under the more uniform and definite control of scientific procedure, has been my aim in the experiments which have resulted in the present method. This method I have named "photo-mezzotint," not because that is the most exact term by which to denote it, but because all the other good names have already been pre-empted and made to do service in other directions.

The essential feature of the new method lies in the fact that the picture, instead of being obtained from a graduated depth of the engraving, is produced from a sunken surface of uniform depth, the gradations of light, half-tone and shade being effected by minute lines and stipples of varying thicknesses, but of uniform distance apart from centre to centre. In this respect the photo-mezzotint may be regarded as a development of the so-called half-tone relief process, the true mezzotint or photogravure effect being attained by reducing the thickness of lines and stipples, and multiplying their ratio to the surface to such a degree as to render them invisible to the naked eye. In that way all the finest gradations from pure white to deep black are obtainable, with the result shown by the specimens before us. In these the picture is made up of equidistant stipples, varying from a microscopic point up to a size where they coalesce into a solid black, the half-tones consisting of stipples of about one four-hundredth of an inch in diameter, and about 44,000 to the square inch. If a coarser stipple is used, the effect varies from that of a mezzotint and approaches more nearly that of a line engraving, the lights and shades being made up of perceptible lines and stipples, like the effects of a steel or copper plate engraving of equal texture.

The processes at present in vogue for the production of photo-intaglio plates require not only long experience and a high degree of manipulative skill, but also take up quite a length of time—frequently a week or more—for their completion, and the plate, after passing the stages of the photo-chemical process, has then still to be extensively helped by the work of the retoucher. The retouching of photogravure plates inevitably introduces a degree of uncertainty as to the accuracy of the reproduction, the

result as left by the retoucher being frequently very different from the original in its disposition of lights and shades. By this new process all these undesirable factors are eliminated; its manipulations are far more facile, the length of time for the entire work is reduced to a few hours, and the result is complete without the supplementary aid of the skilful engraver, except, possibly, in cases of local blemishes or accidental defects. It is therefore reasonably to be assumed that this new method of intaglio engraving, which has been made the subject of an application for letters patent, may be regarded as a desirable addition to the category of the graphic arts. LOUIS E. LEVY.

DEVELOPMENT.

[Holborn Camera Club.]

THE subject of development is one from which we may all learn something, and cannot learn too much, and it is one which the worker in photography must thoroughly master if he ever hopes to take a prominent place in the photographic world. How many of us here to-night know how to develop a plate properly? It is the stumbling-block over which we all fail; it is the blow that shatters all our hopes. Everything was right up till then; the day was fine, the wind still; the exposures were thought right, notes carefully made; but in the development all our hopes were shattered.

Now, why did we fail in development? The developer was made right, and carefully measured out according to the instructions, and yet it all went wrong. The plate is perhaps full of detail, but "Oh, so hard!" or else it is flat and foggy; that cherished little bit of distance, or those charming reflections in the water are all blocked up, and certainly will not print out. What is the consequence of this? Either the plates or the developer were wrong. But this need not be if we would only (to use a well-known writer's words) mix our developer with a little brains, instead of always going by the instructions on the box, which are, to my idea, greatly misleading in most cases.

Now, I must assume, for the time, that we all know something regarding exposure, as the two things are so closely linked one with the other that it is almost impossible to separate them.

My idea this evening is not to give you a list of the various developers, and formulæ, and the results from each which we have had so often brought before our notice, nor to advance one developer or style of development as right and all others wrong. I may mention here that the developer I use, and shall use to-night, is the plain pyro and ammonia with a little sulphite of soda, but I do not for one moment say that this is the best, or better than a pyro-potash or pyro-soda developer. They are all good developers, and equally good results can, in my mind, be obtained from either.

What I rather want to say is that in development, treated rationally and in a business-like manner, we have at our disposal the means of producing in the negative something like the image we saw on the focussing screen. And if, when we expose our plates, we were only to give some consideration as to how we should develop them, we should not give such fearful exposures, nor work the shutter at such a tremendous speed. The consequence would be that the average of our results would be considerably higher, and our plates would not find their way into the dust-box so often.

THE DEVELOPER.

Now, a few words as to the developer and how to make it up.

The pyro, the real developing power, I use dry. In my mind, it is much more convenient to use, and it is more energetic, than when made up in solution with anything else. *The ammonia* I keep diluted to half strength, although, perhaps, a ten per cent. solution would answer better. *Bromide of ammonium* I have made up in a solution of a grain to a drachm of water, which is very simple, and from which I can get any formula. *Sulphite of soda*, which is useful in keeping the plate clean, I make up in a ten per cent. solution. Altogether, my developer consists of four bottles; but it is far better than having the bromide mixed with the ammonia, the same as is so often recommended.

EXPOSURE AND DEVELOPMENT.

Going on, now, to the exposure of the plate, it must be borne in mind that different workers have different ideas of exposure, according to how they intend to develop. One man advocates an exceedingly short exposure, coupled with a rapid and strong development, while the other worker will very much over-expose, and develop with a developer weak in all parts and well watered. They may both be right, but, myself, I am rather inclined to over-exposure and slow development, as I think by that means the lights and shades are rendered in much better proportion, although, no doubt, slight under-exposure and quick development has its good qualities, especially in rather foggy or misty weather, when it is possible by this means to pierce the fog to a certain extent, and get much more brilliant results than could be got by any other method.

Over-exposure, on the other hand, has its good qualities, especially in weak light, such as you get early in the morning or late in the evening, when, by judicious over-exposing, developing for a thin negative, and then intensifying, very good and clear results can be obtained.

I will now briefly go over the different classes of subjects met with in every-day work, and the best proportion to mix the developer; but I must say that these are only hints, as we can lay down no hard-and-fast rule in developing. Every plate requires its different developer and different method in working.

Portraiture.—For portraits we require soft, delicate negatives full of gradation. For such subjects rapid plates are best, as they give softer images; the developer should be kept weak, and the exposure should be very full. A good developer for portraits is—

Pyro	1 grain.
Ammonium bromide	1 ,,
Ammonia	2 minims.
Water	1 ounce.

The negative should not be too dense, but it should be borne in mind that if the lighting is flat, you must use a stronger developer so as to get contrast.

For general *Landscape* work it is as well to use a well-restrained and weak developer, especially if there is much distance; the foreground can generally be brought up by a little stronger developer worked round the plate later on.

Sea, sky, and Clouds.—In these subjects we generally have but little contrast, so all should be done to create contrast by slightly under-exposing and using a developer strong in pyro and bromide. If these subjects are at all inclined to be flat, the best way is to fix the plates as soon as all the detail is out, and then intensify.

In *Interior Work* and *Architectural Work* there are two methods open: to expose slightly under, and use a developer very weak in everything, and well watered, or to considerably over-expose, and use a developer very strong in pyro, and weak in bromide and alkali. Both methods give very fine results. I can hardly say which I consider the best, but my own work is done by the first method.

In *copying*, which is by most amateurs considered the most difficult branch of photgraphy, the great thing is to gain pluck and vigour. This can be got, to a certain extent, by using a slow plate, a short exposure, and slow development; but in all copying, especially albumen prints, if you are not careful in placing the print to be copied so that any reflections are not seen, you will find it almost impossible to get a good plucky negative. In copying line drawings you require a quick developer, and and one giving good density, as, if you are not careful, the fine lines will clog before you get sufficient density.

In subjects which are known to be very much under-exposed, although first-class negatives can never be got from them, still very fair results can sometimes be got by first soaking the plates in a weak solution of ammonia—say two drops to the ounce—for six or seven minutes, then using a developer strong in pyro and ammonia.

Before concluding, I should point out one thing more in development, and that is to tell if the plates are under or over-exposed when the image first appears.

It is the generally accepted rule that an over-exposed plate shows signs of development very quickly, and under-exposed very slowly, but this rule cannot always be relied on. Take, for instance, a plate which has been very much over-exposed on a dull or foggy subject, and in a dull or weak light, such a plate will sometimes be a considerable time in the developer before there are any signs of an image forming, but when it does come it generally comes all at once. Again, on the other hand, take an interior which has been slightly under-exposed and developed with a weak and well-watered developer. Such a subject will develop very quickly. That has been my experience, so you will see that it is as well to study the first appearance of the image, or else you are very often liable to treat an over-exposed plate for under-exposure, and consequent failure.

In conclusion, I may say that I have given no definite method of development, as practically there is none. Every plate requires its separate development, according to what it is, under what conditions of light and exposure it was taken, and what you require in the resulting negative, but can only hope that members of this Club will give themselves to spending more time in the development of their plates, remembering it is the chief point towards successful photography. JOHN H. AVERY.

THE HELIOCHROMOSCOPE.

[Photographic Society of Philadelphia.]

IT was in 1888 that I first described and demonstrated, at the Franklin Institute, a method of reproducing the natural colours by photography, which differed in certain vitally important particulars from somewhat similar processes which had already been carried out by Cros and Du Hauron in Paris, Albert in Munich, Bierstadt in New York, and others. I succeeded in reproducing the natural colours in landscapes and various objects with a degree of accuracy which I have good reasons to believe had never before been approached by any method without the intervention of the artist's brush. The procedure was, however, too complicated and difficult for profitable commercial application, and comparatively few specimens were made.

I now present to your notice devices which so greatly simplify the operation of the process as to make it quite possible to place it in the hands of even the "press-the-button" class of amateur photographers, and yet yield results that are no more defective in colour-rendering than the ordinary photograph is in the rendering of monochrome light and shade.

The first of these devices is a camera attachment by means of which the three pictures representing the effect upon the three fundamental colour-sensations are made by a single exposure on a single sensitive plate, and from a single point of view. The device as now perfected is surprisingly simple, being comprised in a small box, which may be attached to the front board of an ordinary camera. The division of the light-ray is effected by transparent mirrors, as in some of my earlier cameras, but in such manner as to dispose the images symmetrically on a single plane, without altering the position of the camera in relation to the object.

The second device, which I call a heliochromoscope, contains the same arrangement of mirrors, turned about so as to serve to recombine the three photographs in such manner that the photographic colour-record is translated into colour again as readily as the sound-record in the phonogram is translated into sound in the phonograph.

The most important advantage of this device is that it may be used at any time, at a minute's notice, like the stereoscope; and, as almost everybody may possess one, it is competent to make the realisation of colour-photography a household affair. It also more completely fulfils the theoretical conditions of success than either the production of colour-prints or lantern projections, and produces an illusion of nature more perfect than would be possible with even an absolutely perfect colour-print on paper, because the picture is seen without surface reflections or distracting surroundings.

I claim for this system of colour-photography that it is perfectly rational and scientific, and a true solution of the problem of reproducing the natural colours in a photographic picture. This claim meets with a good deal of opposition in the minds of some people, whose mental attitude is a source of wonder to me, because the same sort of objections that are made to the triple photograph would apply to the stereogram and the phonogram. One is an automatic record of colour, another of binocular vision, and another of sound; each must be placed in a special device in order to reproduce that which it has recorded—the triple photograph or chromogram into the heliochromoscope, the stereogram into the stereoscope, and the phonogram into the phonograph. I do not remember ever to have heard the stereogram denounced because it is not a single print with embossed relief, or the phonogram because it has no lungs.

Some even go so far as to deny that this can properly be termed colour-photography at all, although the same individuals are in the habit of calling pictures that cannot be made to show colours "orthochromatic" or correct-colour photographs. But the most extreme illustration of this peculiar attitude of the mind that I have seen is the assertion of one who, if I am not mistaken, has aspired to be the historian of photography, that this is merely "looking at ordinary photographs through bits of coloured glass!" To be consistent, this writer should describe the stereogram as "two ordinary photographs, mounted on the same card," and the phonogram as a "wax cylinder having a roughened surface like an ordinary file." I believe he did recently write a history of photography, with "an introduction to its latest developments," without once mentioning colour-sensitive plates.

I speak of this kind of criticism because it comes from men whose writings are in demand, and proves the existence of a deep-seated prejudice, which I have encountered in the development of other applications of photography, and which must be combated in order to overcome it. I will give an illustration. When, in 1880, I succeeded in realising a mechanically accurate and practicable method of half-tone block-making, I could find only one engraver who believed there was a future for processes that rendered the shading in equally spaced graduated lines and cross lines. Engravers, printers, publishers, and photographers were agreed that if a block be made up of lines, those lines must follow the contours of the object depicted, as in the conventional wood-engraving. Since that could not be done, a grain, similar to the well-known lithographic grain, must be substituted for the line tint. I declared that the objection to a regularly lined tint was a prejudice, stuck to it, and already, within twelve years, plates having that same lined tint have come into such extensive use as to replace millions of dollars' worth of wood-engravings. They are used in illustrating books and periodicals of the highest class, and the advantages of the mechanical lined tint are such that it threatens even to invade the domain of photogravure. Mr. Louis Levy exhibited such results at the last monthly meeting of the Franklin Institute, and I myself applied for a patent on a printing-plate of this character more than a year ago, having first experimentally demonstrated certain important advantages which they can be made to possess.

We did not make half-tone printing plates of the kind that engravers, and printers, and publishers thought they must have; but they concluded to take what we did make, and are taking them more and more every year.

We have not made photographs in the natural colours of exactly the kind that people have been looking for, and there is good reason to doubt if such a result will ever be accomplished; but we have actually realised, by a process almost as simple as stereoscopic photography, results better than can even be hoped for in colour-prints, and so perfect that they must ever represent the standard which results by any other method must be made to approach in order to be acceptable. A good many people seem to think that this is not what they want; but I have quite as much faith in the future of the heliochromoscope as I ever had in the future of half-tone block-making in line. It has been a revelation to me, and I believe it will be to the whole world.

I met a professional artist in London, a clever painter of both portraits and landscapes, who spent what seemed to me a very long time studying a bouquet of flowers reproduced in the heliochromoscope, and left it only to return to it again and again, as if it fascinated him. At last a friend asked him for an expression of opinion upon the merits of the device. After some hesitation, he said that he had attended one of my lectures at the Royal Institution, hoping and expecting to go away and report the failure of another attempt to reproduce the natural colours by photography. He had not been able to do so, but was forced to confess that colour-photography is a fact. The demonstration was conclusive to him. The heliochromoscope will have no better friends than the artists, for whom it will not only reproduce nature, but the masterpieces of art as well, in such manner that they can be studied in far-distant lands almost as well as in the galleries where they repose.

In the far West I met the representative of a large New York firm of importers of Oriental rugs. He assured me that he was ready to pay a hundred dollars out of his own pocket for a duplicate of the heliochromoscope that I showed him, with a set of photographs of the rugs that he carried about with him only to show their colours. It would save his firm a good deal of money that went in expensive sample rugs, and in cost of extra baggage, and it would save him a good deal of trouble. A professional house-decorator spoke much to the same effect. Evidently, the heliochromoscope will have many fields of usefulness, so many, perhaps, that its function as a source of drawing-room entertainment, for which alone many have supposed it to be adapted, will prove of secondary importance. But I shall be greatly surprised if, even for the latter purpose, it does not become more popular than the stereoscope ever was, although it is necessarily a much more expensive instrument.

F. E. Ives.

SCIENTIFIC RESEARCH IN PHOTOGRAPHY.*

There has been of late a wholesome spirit of emulation in the different classes of work, and a happy tendency among our members to abandon the old albumenised paper printing, and to turn attention to the superior results obtainable by the platinum (hot and cold bath), the carbon, the bromide, the gelatino-chloride, and plain salted paper processes, specimens of each of which can be inspected to-night. The desire is to gradually raise this Club out of the narrow groove of ordinary photography, and in the near future to encourage scientific inquiry into the causes of the various phenomena connected with the subject by independent original research. More men are wanted—earnest workers in all branches which the amateur can, with the aid of a little perseverance, master, viz., photo-micrography, meteorological photography, photographic ceramics, and also some of the simpler photo-mechanical operations. Then, others are wanted who will experiment in the direction indicated by the Diazotype, the production of photographic impressions by means of the aniline dyes. And lastly, some men with a certain amount of training in chemistry and physics, who will devote some of their efforts to the solution of that very difficult problem, photography in natural colours.

A short account of what had been done in this direction from the time of Dr. Seebell, in the year 1810, downwards to the researches of Edmund Becquerel, with dates and names of chief workers were given in a paper by the Vice-President (Mr. W. H. Harrison) in the *Photographic News Year-book* for 1890, and any one contemplating experiments in this direction, cannot do better than refer to the article.

* Extract from the Presidential Address at the opening of the Brixton Camera Club Exhibition, November 17, 1892.

It appears that the first person to obtain coloured impressions upon paper prepared with chloride of silver was Dr. Seebeck, in 1810. Next, Sir John Herschel, in 1839 and 1840, in a communication to the Royal Society, stated that he had obtained a coloured impression of the solar spectrum on paper prepared with chloride of silver. Afterwards Hunt, in 1844, stated that fluoride of silver is very sensitive to the coloured rays, and that the yellow was well marked. That particular colour could hardly be detected in the images by Seebeck and Sir John Herschel. Then followed the splendid experiments and researches of Edmund Becquerel, an investigator who did more than almost any one to develop colour photography, and his best results were obtained by taking a highly polished silver plate and depositing thereon, by means of the voltaic current a thin film from a solution of the perchloride of copper in an aqueous solution of chlorine gas, and subsequently drying the plate by means of a gentle heat, and on plates prepared in this way he is said to have obtained all the colours in a picture. More recently—in fact, down to the present moment—M. Lippmann has not only produced photographs in natural colours, but has shown us that the result is brought about by the interference of light, and that to get a vivid impression it is necessary to have a brilliant, reflecting surface in optical contact with the sensitive film, and that, no doubt, is why the coloured images which were occasionally produced on the old Daguerreotype silvered plates were produced—viz., because the actual surface of the plate was iodised, so that there was necessarily absolute contact between the sensitive and the reflecting surfaces. Lippmann's plan is to coat a glass plate with collodion or some other transparent medium containing bromide or other salt of silver, and then to make the prepared plate one side of a cell or trough with the sensitive film turned inwards, and the cell so produced is then filled up with pure mercury. In this way a brilliant surface is in optical contact with the sensitive film, and after due exposure the plate is developed with pyrogallic acid, and fixed with the usual hyposulphite of soda solution, when a faintly coloured image results. I have tried the effect of exposing a bichromatised gelatine plate under a number of strips of different coloured glass to bright sunlight, but obtained no pronounced result, no doubt because I omitted the indispensable reflecting surface, as I find Lippmann has tried the same experiment with the addition of a reflecting surface, and has thus obtained his best and latest results.

Considering the large number of persons who, from various causes, practice what has been facetiously called the "black art," it seems almost impossible but that there must be a goodly number present who have had a certain amount of scientific training in chemistry and physics, and a knowledge of these subjects is an immense help, no less to the beginner than to the advanced worker. I cordially invite all who have had that training and who happen to be present to attach yourselves to the Club, and thus not only give the members the benefit of your superior knowledge, but to contribute your mite to the further development and ultimate success of our scheme for the establishment of the Society on a sound scientific basis. Let not beginners be frightened away by the projected programme. All must have a beginning, and failures frequently teach us more than our successes. I trust that this Exhibition will be the means of causing a large accession of members, for it is not to be forgotten that photography is not only one of the most fascinating and absorbing hobbies that it is possible to take up, but that it requires for its successful accomplishment patience, care, neatness, cleanliness, precision, and close observation, combined with thoughtfulness, and so directly tends to develop those qualities which are absolutely necessary if we would make life a success. J. Reynolds, M.D., F.R.G.S.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

The third condition that has been laid down as being necessary before the Kew method gives theoretically correct results is that the nodal point should be the same for white light as for photographically actinic rays. This may be hypercritical, but if, in fig. 5, C″ and B″ represent the images as seen on the photographic plate, C′ and B′ those seen by the eye on the ground glass, N_1 the mean position of the nodal point of emergence for visible rays, and S the mean position for actinic rays, then it is evident that FN_1 will be the principal focal length found by the observation, whereas SF will be the quantity required in calculations with regard to enlargements or illumination. If the lens give any distortion, N_1 would represent the centre of similitude for visible rays and S that for photographically actinic rays; the condition might, therefore, have been more rigidly defined by stating that the point of similitude for visible rays and that for actinic rays must occupy identical positions for parts of the field between the points of observation. As far as can be judged, this is a negligible source of error in all cases.

Continued from page 745.

A fairly large angular movement of the swinging beam, about 14½° on each side of the axis, has been adopted at Kew in order that any error in the measurements on the ground glass may produce a small proportional error in the results. But it should be observed that the smaller this angle, the less will be the errors just discussed, and by lessening the angular movement these errors can be reduced to any extent, but only with a proportional loss in the general accuracy of the results obtained.

This is not the place to enter into a general discussion on focometry, but a few words to justify the choice of the Kew method may perhaps be permitted. Many of the known means of finding the principal focal length depend in principle on measuring the relative size of the object and the image, and the foregoing remarks on the errors involved are more or less applicable to them, thus showing that they are open to the same criticisms on theoretical grounds as the work at Kew. Many methods of focometry have to be rejected because they do not measure the distance from the nodal point, and others are unsuitable because the calculations or successive adjustments involved render the operation too lengthy. There are, no doubt, many instruments—as, for instance, that devised by Professor Silvanus Thompson—which do give the true focal length as measured on the axis with theoretical accuracy, but these have not, as a rule, been specially designed for photographic lenses. One method, which is hardly open to criticism on theoretical grounds, may be mentioned in a little greater detail as being that specially recommended by the International Congress of Paris; this is the elegant plan which Commandant Moëssard proposes to carry out by means of his instrument, called the *Tourniquet*, which is described in Wallon's *Traité élémentaire de l'Objectif Photographique* and elsewhere. Advantage is taken of the principle that if a lens is revolved about an axis passing through the nodal point of emergence, the image of a distant point will not appear to move if seen through a fixed eyepiece; thus, by successive adjustments and trials, the lens can be so placed that an axis does pass through the nodal point; and, by measuring the distance between this axis and the focus of the eyepiece, the true focal length can therefore be obtained. Since a movement can be detected before it can be measured, a smaller angular movement is required with this method than with the Kew testing camera, and therefore, as far as distortion is concerned, greater, but not absolute, theoretical accuracy is obtained. As for the coincidence of the visual and actinic centres of similitude, better theoretical results are only obtained by this method on the assumption, which is probably a true one, that these points approach each other as the point of observation gets nearer the axis.

By taking observations some fourteen degrees away from the axis of the lens, we conclude, therefore, that we obtain the most rapid and accurate method of focometry; and, in the case of the image within this limit being disterted, that the focal length thus obtained, even though it is not identical with the principal focal length measured on the axis, is what the photographer in reality wants to ascertain. The Kew method is therefore, we believe, open to no criticism on theoretical grounds as far as the value of the results is concerned.

Under the same heading as the principal focal length is also recorded the "back focus," or the length, from the ground-glass surface to the nearest summit of the lenses, when the focus is adjusted on a distant object. The difference between the principal focal length and the back focus therefore gives the distance of the nodal point of emergence from the inner summit of the lenses, thus enabling any one to mark the place where the principal plane cuts the mounting. In symmetrical lenses, which are generally used for plan work, the position of the principal plane of incidence, or the point from which the distance of the object must be measured when regulating enlargements, can also be marked; for it then occupies the same relative position with regard to the furthest summit of the lenses—that is, to the outside end of the lens—as the nodal point of emergence does to the inner summit of the lenses.

12. *Curvature of the Field, or of the Principal Focal Surface. After focussing the plate as its centre, movement necessary to bring it into focus for an image —— inches from its centre = —— inches.*

Ditto for an object —— inches from its centre = —— inches.

" " —— " " = —— "

The following is the method of finding the curvature of the principal focal surface. The image of a distant object (or of the collimating telescope) is thrown on that point on the ground glass where the axis of the lens cuts it, the focus is accurately adjusted, and the focus scale is read off. The swinging beam is then moved so that the image comes succes-

sively to positions at convenient intervals from the centre of the plate, and on each occasion the focus is adjusted afresh, and the focus scale read off. By subtracting the central reading from these outer readings, the results recorded in the Certificate of Examination are obtained.

But a mere observation of the curvature of the focal surface does not at once indicate how serious is the evil effect of this defect in the lens. Further consideration is necessary to settle this point. If the results furnished by this test are plotted in the form of a curve, they will represent a section through the principal focal surface; let A F in fig. 6 be

Fig. 6.

such a curve, and let $c\,d\ (=\mu)$ be the movement necessary to bring the plate into focus at its margin; let N_1 F be the principal focal length, and E G $(=s)$ the effective aperture of the lens. The effect of this curvature is to make the image of a point appear on the plate as a disc, except on the circle or at the point where the principal focal surface either cuts or touches the plate. If the photographic plate is in the position M′F′, such that it bisects $c\,d$, then the discs of diffusion will be greatest at the centre and at the margin of the plate; and any movement of the plate from this position will increase the size of the disc at one or other of these places; if the photographer adjusts his focus so as to produce the best general focus, $e\,g\ (=\delta)$ will therefore be the diameter of the largest disc of diffusion on his plate. Assuming that this position of the plate has been adopted, and that the lens gives no distortion, then, by similar triangles, it can be seen that—

$$\mu = \frac{2\delta}{s}(f-\mu) = \frac{2\delta f}{s} \text{ nearly} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1).$$

But the C.I. No. of stop $= \frac{f_2}{100\,s^2}$; and therefore

$$\mu = 20\delta\sqrt{(\text{C.I. No. of stop})} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots(2).$$

The accompanying Table gives the value of δ for the different value of μ and for stops of different numbers; and thus the size of the greatest disc of diffusion can at once be seen from the results of the examination as recorded in the certificate.

When judging the quality of a lens by means of the results given in this test, the above table may also be used in the following manner:—Decide on the value of δ (the diameter of the greatest disc that will be tolerated in the image of a point), and find, from the results recorded in the Certificate of Examination, the difference of focus, μ, between the centre and the extreme corner of plate; then, knowing these two quantities, the table at once shows what is the C.I. number of the stop that can be employed under these conditions, or, in other words, with what rapidity the lens will work.

It may also be remarked that this table gives for any part of the plate, and for stops of given size, the *radius* (δ) of the image of a point after the plate has been removed a distance, μ, from its proper focus in either direction, the movement being measured in a direction perpendicular to the plane of the plate.

According to the recommendations of the International Congress, lenses should generally be supplied with stops, numbered according to the proposed system, in the following series: 1, 2, 4, 8, 16, 32, 64, &c. I should have thought that the series, 1, 2, 3, 5, 10, 20, 30, 60, &c. would have been more convenient for the purposes of mental arithmetic; for example, with the two last stops in this series, the exposure would be the same multiple of the half minute or minute that the unit of exposure is of the second. Both series have therefore been included in the above table.

The results recorded in the certificate under this heading may possibly also be useful to the photographer in another way, by enabling him to decide approximately what part of the ground glass he should use when

Table giving μ (the difference of focus in inches of the centre and the margin of the plate; or, after focussing the plate at its centre, the amount it has to be moved to bring the margin into focus) with reference to the size of disc of diffusion and number of stop.

C.I. No. of Stop.	δ, the diameter, in decimals of an inch, of the maximum disc of diffusion when the plate is in the position giving the best general focus.							Approximate ratio of effective aperture to focal length.

focussing. In fig. 6, let k be the point where the plate M′F′ cuts the principal focal surface when in the position which has been proved to give the best general focus; hence the image will be perfectly sharp at k, and conversely, if the focus is adjusted by looking at the point k on the ground glass, the plate will be brought to the position M′F′ required; but, since kl is half cd, there is no difficulty by interpolation or plotting to find the approximate position of k for any given distance of the point c from the axis. Look in the Certificate of Examination for cd, the difference of focus between the centre of the plate and its margin, find in the above manner the position of k, where the difference of focus from the centre is only half cd, and we get the point on the ground glass which should always be used when focussing with all stops, if it is desired to get the best general focus.

Leonard Darwin, Major R.E.

(To be continued.)

PHOTOGRAPHIC EXHIBITION AT THE "STANLEY SHOW."

Without in any way decrying the popularity, utility, or success of the Stanley Show of bicycles, &c., it may be doubted whether the addition of a photographic exhibition to the list of attractions can serve any useful object but the provision of another opportunity for these photographers whose aim it is, *coûte que coûte*, to increase their stock of medals. In justice to photography itself, we feel bound to point out that it has long since established its right and capacity to appeal *per se* to the sympathies of every cultivated section of the community, and therefore can afford to stand alone without outside assistance. We are the more confirmed in these reflections from having noticed that the "Stanley" Exhibition of Photographs, held as it was in a comparatively out-of-the-way room, appeared to be neglected by the vast majority of the visitors to the "Show"—a fact to be explained on several grounds, notably the one that those who went to the Agricultural Hall were almost entirely interested in the main attractions. Briefly, the photographic exhibition seemed a little out of place.

These remarks, however, in no way discount either the energy of the promoting Society, which we hope will meet with the reward sought, or diminish the artistic success of the photographic display, which we hasten to own was unmistakable. The Judges—Messrs. Andrew Pringle, Henry Sturmey, and J. Traill Taylor—have been congratulated on the happiness of their awards, with which no one appears to find serious fault. For those visitors who could spare an hour away from the bustle of the microcosm of the great cycling industry outside, the collection, small as it was, was well calculated to convey a very good idea of latter-day photography in some of its best phases.

It is not a little singular that the class which more than any other would seem to have given this photographic exhibition its *raison d'être*, namely, that for instantaneous cycling subjects, should have only had three sets of pictures sent in. Mr. W. H. Kitchen received the bronze medal for his snap-shots of racing cyclists, neither the gold nor the silver being awarded, Mr. A. C. Edwards taking a diploma for his series. In B (instantaneous general subjects) much creditable work was shown, Mr. J. H. Gear (a clever worker) taking the gold medal for his series, of which the yacht picture *Running into Harbour* was full of life and sparkle, and his sheep subject *Repose—Morning Light*—most artistic in the lighting and groupings. Mr. A. C. Edwards' silver medal for his hand camera shots at Niagara Falls was thoroughly well deserved, their selection and technique being irreproachable. Mr. E. M. Stone took the bronze medal for four views at Filey. Mr. Dresser's diploma pictures, notably the *Boat coming Ashore*, were good; but Mr. Dresser should guard against spotty prints. Mr. A. S. Statham also received a diploma for four small pictures, of which we preferred his nicely-finished *Ramsgate Harbour;* and Mr. E. Hawkins for *Ploughing* (an excellent study), *Off to the Rescue* (boatmen shoving off), *Grazing*, and *Becalmed*, the first-named irresistibly reminding us of Mr. Dresser when Mr. Dresser is at his best. Mr. F. W. Grants' seaside snap-shots were chiefly remarkable for their bilious tone; and Viscount Maitland's *Evening*, a wild piece of nature, well printed on bromide paper, arrested attention by its unconventionality.

Mr. H. Dudley Arnott received a gold medal for a study of fishing boats, and the same gentleman showed several other sea pictures, all of high merit, *Stalham Dyke, Norfolk*, also justly securing him the bronze medal. Mr. Dresser took a silver medal for an enlargement from a hand camera negative, the vessel ploughing through the waves being very well caught. *Off to Plough*, for which Mr. J. E. Austen gained a diploma, was a charmingly soft study of horses and landscape. The tones of Mr. S. Francis Clarke's series of landscapes were most agreeable, being of a delicate degree of warmth which falls short of obtrusiveness. In *An Introduction* Mr. E. H. Bayston very ably suggested Jan Van Beers' *My Friend Mr. White*, and those who remember that picture will appreciate our admission that Mr. Bayston succeeded in producing a very humorous imitation of it. Mr. J. A. Hodges' *A Welsh Port*, *In Conway Vale*, *Shallow Waters*, *Departing Day*, were prominent, so to speak, by their lack of striving after effect. They were poetical landscapes, faultless in selection, lighting, and printing. In the same class Mr. T. Earp, Mr. T. M. Brownrigg, and Mr. H. R. Leach showed meritorious work; and in *Winter*, by Mr. J. O. Grant, one had a picture of distinct excellence.

Class E, "pictures by the platinotype process, any subject," was especially rich in good things, although Mr. F. M. Whaley was rather fortunate in securing the gold medal for his *Worn Out*, which, when hung at Pall Mall, was passed over. It is a clever picture, but photography is a poor suggester of pathos, as so, for that matter, are most other graphic arts. Mr. Harold Baker's silver medal picture, *Strensham Church*, as well as his two of Tewkesbury Abbey, were probably the finest examples of architectural and interior work in the Exhibition, while his portraits by electric light showed that this artist has a complete mastery of this light in portraiture.

Mr. C. F. Treble's exhibition work continues to show improving excellence, and he rightly took a medal for *The Wretched Criminal*, a small child in a corner with a look of horror on its face at having been bowled out in some petty delinquency. The realism of this clever picture was remarkable. In *Who's Oo?* another baby subject, for which he took a diploma, a little child on its knees is questioning tiny doll, *Three Studies of Ladies' Heads*, and other subjects Mr. Treble proved the possession of versatile powers. The highest position in artistic and *genre* work is already at Mr. Treble's command. Mr. F. W. Edwards received a diploma for a fine reproduction of a Tinworth panel, and also showed several large reproductions of pictures and direct pictures of Westminster Abbey, Canterbury Cathedral, and the Tower, which were all excellent. Mr. W. J. Anchorn received a diploma for a Scotch interior, *Spinning and Reeling*. Mr. Douglas Pym's portrait study, *Sweet Seventeen*, was a very delightful picture of a delightful sitter—soft, artistically posed, and carefully executed. Mr. E. Benson had two capital Westmoreland views, and Mr. Ernest Spencer a fine untouched head study, looking remarkably like General Booth. Mr. Robert Terras showed an artist painting a young lady. As an interior and as a piece of composition the picture was undeniably an able one, but the sketch on the canvas did not correspond with the sitter. There were several pictures, not for competition, and of these Dr. Roland Smith's *Interior of St. Albans* struck us as being exceptionally good.

The awards in the Lantern Slide Class were as follows:—Gold medal, Mr. J. Carpenter; silver medal (two medals), Mr. E. G. Lee and Mr. J. E. Austin; bronze medal, Mr. Austin C. Edwards. Diplomas of merit—Messrs. A. R. Dresser, J. O. Grant, J. H. Gear, and W. Taylor.

Messrs. B. J. Edwards, of Hackney, showed work done with their isochromatic plates; the Autotype Company, carbon reproductions; the City Sale and Exchange, a large exhibit of novelties of various manufacture; W. Wray, of Highgate, a case of lenses. And among other exhibitors were A. F. Smith & Co., of Islington; Londale Brothers, of Leeds; Davenport, of Camberwell; H. Park, of Kingsland; Elliot Son, of Barnet (the Great Wave Picture, &c.); G. W. Secretan; Sands, Hunter, & Co., of Cranbourne-street; Namcit; R. & J. Beck, with their new "Frena" camera and enormous enlargements from negatives taken with it.

BRIXTON AND CLAPHAM CAMERA CLUB EXHIBITION.

Confined exclusively to the work of members, the annual Exhibition of the Brixton and Clapham Camera Club was held on November 17, 18, and 19. In the only two classes—direct prints and enlargments—into which it was divided, less then 300 pictures were included, and as the pictures were judiciously hung, a compact unostentatious little display was the result. On the occasion of our visit, the exhibition room was filled by appreciative visitors, whom we left sitting under Mr. C. W. Hastings' lantern lecture on "Mr. H. P. Robinson," of whom, sooth to say, non-photographic Brixtonites and Claphamites present looked as if they had never heard before.

We have not space for any detailed criticism, and, indeed, as the Exhibition was not an open one, the occasion scarcely requires it, but we may pass a word of commendation to Mr. C. F. Archer for his portrait studies; to Mr. H. Willoughby for his Exeter Cathedral interiors, to Mr. J. H. Edwards for his soft and charming views at Bexley and on the Cray, "Cloud" picture and evening view, "When the sun sinks to rest," a hackneyed subject it is true, but skilfully handled. The same gentleman's Zulu Wedding groups lent diversity to the exhibition. Mr. W. Thomas was a prolific exhibitor, and his small platinotype work admirable, both artistically and technically, was certainly the finest shown. Messrs. Buck (*Ely Cathedral—Interior*), F. W. Grant (*A Misty Sunset*), F. Goldby (*Via Mala, Switzerland*), E. Dockree (*On the Colne*), each had capital examples of their powers.

An excellent and convenient feature of the catalogue was its indication of the printing processes by which the photographs were produced. It may be of interest to note that out of the 290 or so pictures shown, only eight were on albumen-silver paper. In conclusion, we congratulate the Club on its Exhibition, which proved that among its members are many capable of achieving the best results in photography.

EDINBURGH PHOTOGRAPHIC SOCIETY'S ANNUAL EXHIBITION.

In noticing the other works exhibited here, those by Mr. Keene, of Derby, should not be overlooked, comprising, as they do, examples of the best

in the several departments of landscape proper and architectural work artistically treated. Those of Richmond Church, exterior and interior, are very good.

It is almost a new experience to have such a number of fine works by Messrs. G. W. Wilson & Co., of Aberdeen, and those of a class and importance in point of size and subject out of their usual, such as *Bait Gatherers on the Beach*, and the many pictures of the fisher-folk of Footdu (Fitdé) with the spoils of the deep (in one instance *in a clothes-basket*), to the studies of the older people depicted in *Peace* and *Retired from Sea*, and all given in the nearest approach to the effect of sepia drawings with the added truth which photography alone can give, together with selection of subject, whether accidental or grouped, and that keen appreciation of telling character which shows the artistic mind, no matter through which medium it chooses to express itself.

An upright view, looking up a wooded river bed, by Boisonnais, of Geneva, should be an object lesson to many of the members who, with quite as picturesque subjects of a similar kind, fail to hit, or feel, or see the artistic side of their representation. The figure in white gives the key to the whole picture, which, with its wealth of detail, has no obtrusive point, and this one speck gives value to the whole treatment of the subject.

It would be invidious to criticise those pictures of the members which have been taken during the Saturday rambles, as they must, upon the whole, be indebted for excellence more to accident than choice. Nevertheless, many of these show a fine sense of what goes to the making of a picture in the true selection of standpoint. One general fault there is, however, a prevailing tendency to too great a depth of printing. This takes away from the feeling of open-air, daylight work, which is more pronounced where the picture has been aided by sunshine, which should represent brilliancy and brightness, but is, among many of the examples, more like twilight or an approaching thunderstorm. *Reeds at Raith*, otherwise good pictures, are much spoiled by this treatment. "Impressio" should note this impression.

The figure pictures in Class III. are not so much in evidence as usual, perhaps the most notable is a *Breton Holiday*, by Breton. A very small *Fisher Girl*, by Gem, is a gem in its way, but it also proves that for exhibition purposes larger pictures attract the eye in many cases by reason of their size, which might or ought to be a lesson in the hanging and placing of the smaller class of pictures. An interior, by "Combined," showing an old woman lit by windows in strong light and shade, is very effective.

In Class IV. there are several landscapes of a high class, such as those by Forward, Mist, Ondo, and Combined. The Interlaken *Guy Fawkes* is a capitally treated picture, and Agricola's *Gloomy Winter* is a most carefully finished bit of photographic work of a kind difficult to give effect to, but which is here treated in the truest artistic method, in form, in tone, in chiaroscuro, the latter being wonderfully helped by the broadly treated stormy sky contrasted with the delicate rendering of the snow-covered branches of the tree group in the central part of the composition. The same artist's *At the Foot of the Pentlands* gives further proof of the feeling which can be made to invest the most common incident of every-day country life. The long sweep of the hills with their delicate atmospheric effect is a perfect study. This picture would be much improved by less of the immediate foreground being shown, which would make it finer in landscape shape as well. There are many other good works. The best of each class will, no doubt, be selected by the *vox populi* method of decision chosen by the Council.

A MODIFIED MAGNESIUM LIGHT FOR LANTERN SLIDES BY REDUCTION.

[Liverpool Amateur Photographic Society.]

There are difficulties attending the reduction to lantern size by means of artificial light which render the game hardly worth the candle, and still it is absolutely necessary frequently, even from quarter-plate, to reduce in order to produce the best effects. At this time of the year, that erratic and variable quantity "daylight" is unavailable in the majority of cases, and to become entirely independent of it with respect to reducing and enlarging, we require a light which will illuminate a large area with perfect evenness, and still give sufficient intensity to bring the necessary exposure within a reasonably short time. While experimenting in this direction, the simple fact that the portion evenly lit corresponded, more or less, with the size of the flame used, led us to conclude that, when we could produce a sufficiently large flame, our object would be attained. A great many ways in which this might be done have been carefully considered and tested, and *found wanting:* in the best cases the enormous heat evolved was against them. But, notwithstanding, Mr. Potter and myself claim that, by a simple modification, we can induce an old friend to serve our purpose.

We claim to have constructed a means of illumination which is perfectly even over a practically unlimited area, is economical and easy of manufacture, and one which will give good and satisfactory results; and though we claim this, we respectfully submit the idea as a crude one. To put the matter briefly, this light is simply our old friend the magnesium flash-light—but *in sheet form*. Equal quantities by weight of magnesium powder and chlorate of potash are placed between sheets of tissue paper, and this fired while suspended parallel with the negative.

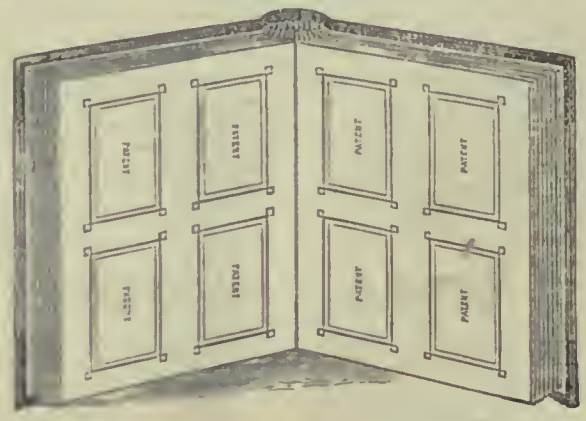
In practice, the following difficulties have been met with:—The carbonised portions of the paper have obstructed the light somewhat, the uneven sprinkling of the light-giving powder has been found detrimental to the best results, and the smoke evolved has been a source of annoyance and discomfort. These difficulties have been overcome, firstly, by using pyroxiline instead of ordinary paper; secondly, by adopting a "pellet" system of spreading the powder and thirdly, by enclosing the luminant in a smoke-trap or box.

Demonstration (half-plate size).—A piece of one-sixteenth inch zinc about 8×6 inches is perforated with holes three-sixteenths inch in diameter every half inch (actual number 117); this, laid on a sheet of the paper, has twenty grains of the mixture spread over it, and swept into the perforations; the zinc being removed, it leaves "pellets" containing about one-sixth of a grain each; a slightly starched or pasted similar sheet placed on top completes the operation, drying under slight pressure being all that is required.

C. B. Reader.

AN ALBUM FOR UNMOUNTED PHOTOGRAPHS.

The Blackfriars Photographic Company have submitted to us a specimen of their albums for unmounted photographs. These can be easily



and quickly placed in position in the albums on account of the division between the spaces being detached from the mounts. It is, we know, the habit of many amateur photographers seldom to mount their prints, and a convenient album of this kind should enable them to preserve them against all the ills to which unmounted photographs are heir.

Our Editorial Table.

Around the Roman Campagna.

By George E. Thompson. London: Simpkin, Marshall, & Co.

This work, by one of the most accomplished photographers and writers, may be considered as a species of companion to his *Spring at the Italian Lakes*, which we noticed about a year since. During his visit to the Continent Mr. Thompson has made good use both of his camera and notebook. In the present work the author takes us pleasantly through and around the Imperial city, and affords us a good insight into the manners and customs of those with whom he comes in contact, and all the time never forgets the rich scenery. This attractive work is illustrated by six selections from Mr. Thompson's photographs, beautifully printed by the Photophane Company. The price of the book is 4*s*.

Christmas Annual of The Practical Photographer.

London: Percy, Lund, & Co. Price 1s.

This Annual consists of eight studies, selected from the works of various photographers, and which have from time to time appeared in the pages of the *Practical Photographer*. They are accompanied by two pages of descriptive letterpress, in which a brief outline sketch of each is given.

Photographs of the Year, 1892.

London: Hazell, Watson, & Viney, Limited, 1, Creed-lane.

This handsome work comprises twelve reproductions of photographs shown at the Pall Mall Exhibition, together with a critical survey of the entire collection. Both selection and critique have been entrusted to Mr. Horsley Hinton. The photographs he has selected for reproduction include Mr. F. Muller's *Portrait*, Mr. B. G. Wilkinson's *Silver Strand*, Mr. Burchett's *Love Letter*, Mr. Austin's *Worn Out*, Mr. Lord's *How's that?* and pictures by Messrs. J. K. Taylor, Brownrigg, and others. The reproductions are artistically charming and faithful to the originals, notably in the cases of the first two we have named, where the printing process is imitated wonderfully well. Mr. Hinton, who is always clear and intelligible, is distinctly impartial in his critique. *Photographs of the Year* is an elegant work, and all concerned in its preparation are to be congratulated.

Mr. Jonathan Fallowfield has shown us specimens of his floral opaline tablets for window or studio, inscribed with *Terms cash* and similar necessary reminders, together with floral borders with Christmassy aspirations printed on them, and spaces left in which *carte-de-visite* photographs can be mounted. Both novelties should be useful, particularly the latter, at this time of year.

Lantern Slide Manual.

By John A. Hodges. London: Hazell, Watson, & Viney, 1 Creed-lane, E.C.

Mr. Hodges' manual appears at a seasonable time. In the course of five sections it treats successfully of slide making by reduction and contact, by the collodion, gelatine, and albumen processes. The information, if (as the author frankly admits) not new, is at least tolerably exhaustive and clearly presented. In speaking of the gelatino-bromide process, Mr. Hodges very truly observes that "success in making lantern slides depends largely upon the amount of attention that is paid to little matters of detail." The book is full of those details, and is freely illustrated, and should prove a serviceable guide to the amateur undertaking lantern slide work.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

November 22,—Technical Meeting,—Mr. A Cowan in the chair.

Preparing Photographs for Exhibition.

In the course of a short discussion on this subject, Mr. W. Bedford thought it would be well to have it understood that pictures in unusual frames were not calculated to harmonise with the others, and that therefore they might have to be placed in undesirable positions.

Mr. W. E. Debenham, as regards the frames, thought that exhibitors should be left to exercise their own tastes, as possibly what one might consider artistic would be voted by another vulgar and offensive.

Mr. Chapman Jones said that when he had anything to do with exhibitions he had found the difficulty of hanging together those pictures which were surrounded by a large margin with those which were framed close up.

The Chairman had never seen pictures to more advantage than at the Crystal Palace. In one bay there were pictures with large margins, and in another pictures framed close up, and so on. There was no reason why pictures should be packed close together. Mr. Bedford's exhibition pictures, for example, should have a little margin round them.

Mr. A. Mackie referred to the case of a set of photographs printed on deep pink paper, the mounts being bright blue with gold lines.

Mr. Debenham instanced a celebrated picture which was passed by the Judges on account of the frame. He did not think Judges were influenced by the mounts of photographs as seemed to be thought, and remarked that the Chairman and probably every one present were quite capable of judging photographs whatever their mounts might be.

Mr. Chapman Jones said that when prints on the walls of an exhibition actually faded in six weeks it was time to say that prints must be done by some permanent process. Of course it was difficult to draw the line, and something ought to be done in that direction.

Mr. Debenham said the objection raised by some exhibitors to state the processes by which their pictures were produced was unreasonable, and thought that for educational purposes they should be stated where they were not evident.

Mr. Bedford thought, in judging photographs as works of art, it should not be stated as a merit that they were produced by any particular method.

Ferrotype Photography by Flashlight.

Mr. L. Nievsky gave a demonstration of flashlight photography with dry ferrotype plates. The plates are contained in a receptacle placed on top of the camera, and after focussing one is placed in position, and the exposure being made it passes into a chamber where it is submitted to the successive action of the developing, fixing, and washing baths. Mr. Nievsky took the portraits of several of the gentlemen present. He observed that the first few plates were generally fogged, but as soon as a little of the hypo got mixed with the developer clearer pictures resulted.

Mr. J. A. Harrison exhibited a camera-stand attachment for enabling the camera to be tilted at a considerable angle. It consisted of a double frame, the lower one being fixed to the tripod, the upper one, to which the camera is attached, apparently moving by means of a lazy-tongs attachment.

The meeting then concluded.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 17, Mr. Lewis Medland in the chair.

Messrs. Williams (of Rhyl), F. Scott, W. Packham, and L. J. Atkinson were elected members.

Mr. H. Rapson produced the negatives referred to at last meeting. The reason assigned for the stain was insufficient washing before intensification.

Removing Silver Stains from Negatives.

Question: "Is there any reliable formula for removing silver stains from gelatine negatives?"

Mr. J. S. Teape said he could always remove such stains with alcohol, and stated that, when applying it, it was advisable to work on as large a surface of the negative as possible.

Mr. W. Debenham considered that rubbing with alcohol reduced the density of the negative, which was not always desirable.

Mr. P. Everitt referred to a statement in one of the journals that Mr. Horatio Nelson King had discovered a process for removing silver stains, but it was not yet published.

Mr. Snowden Ward had heard from a professional friend of his that prolonged soaking in hypo, say, for as much as twenty-four hours, would remove the stain satisfactorily.

Mr. Debenham said that silver reduced by development is in a very different condition to that reduced by light, therefore it might be expected that strong hypo might affect the silver when in the brown state, while it would not affect it in the black form.

Mr. Snowden Ward, as to the prevention of the stains, would recommend the use of two different kinds of varnish on the negative, one on top of the other.

The New Methylated Spirit.

The Chairman asked what course to pursue to obtain pure methylated spirit? In using the spirit as sold now, he had found a great difficulty in removing the greasiness from the films.

Mr. A. Cowan stated that it was necessary to apply to Somerset House for a permit to obtain the pure spirit from a methylator.

Mr. J. S. Teape, with reference to the use of ordinary as against chrome alum, produced some prints on "Hutinet" paper, which he said, before development was finished, were covered with large blisters. He tried soaking before development in ordinary alum, which he found greatly reduced the size of the blisters, but they were still all over the print; but, treating other prints with a preliminary bath of chrome alum, four grains to the ounce, he found, on development, no trace of blisters.

This being the Monthly Lantern Night, slides were shown by the Chairman (Mr. Medland) of various animals and rare birds at the "Zoo," and views at Yarmouth and elsewhere, and by Mr. J. A. Sinclair of views in Belginm, and also by Messrs. Everitt, Dando, and Debenham.

It was announced that December 1 would be a special lantern night, Mr. F. W. Hindley having promised to show his large collection of slides entitled *Scenes from Ireland*.

Holborn Camera Club.—November 18, Mr. H. Thompson in the chair.—Mr. J. H. AVARY read a paper on *Development* (see page 758.) He developed a number of negatives after reading his paper, and also a large transparency on an ordinary plate.

Fillebrook Athenæum (Photographic Section).—November 21.—Preliminary arrangements were made for the Exhibition on March 1 and 2, 1893. Discussions followed on the subjects of transparent markings on gelatine lantern plates (which it was suggested might be caused by imperfect mixing of the emulsion) and the new amidol developer. With regard to the latter, Mr. H. W. BENNETT showed six negatives taken with a view of testing the relative developing powers of amidol and pyro. Three Ilford Ordinary plates were exposed for four minutes each, a Mawson, an Ilford Special Rapid, and an Ilford Ordinary for two minutes each, the subject being a light vase. One of the Ilford's that had received four minutes, the Ilford Special Rapid, and the Mawson were developed with pyro and ammonia, proving, as intended, somewhat under-exposed, the Special Rapid very much so, the negative being very poor and badly stained from forced development. The Ilford Ordinary and the Mawson gave very fair negatives. Another four minutes Ilford Ordinary was developed with pyro, potash, and soda, this requiring very prolonged development to give the same vigour and detail as in that treated with pyro and ammonia. The third Ilford Ordinary that had four minutes' exposure was developed with amidol, the stock solution mixed according to the maker's instructions, being diluted with three times its volume of water, and also restrained with a half grain of bromide of potassium to each ounce of solution. The development was completed in about two and a half minutes, the deepest shadows commencing veiling, the appearance of the plate being that of one considerably over-exposed. The Ilford Ordinary that had received two minutes' exposure was then developed with amidol, the composition of the developer being exactly the same as in the preceding. Result, full detail and good gradation, though too thin to be considered a good printing negative; no stain or fog of any kind. This result was obtained with an exposure that had failed to produce a presentable negative at all on an Ilford Special Rapid, which is said to be twice as fast as an Ordinary. In this case Ilford Ordinary, developed with amidol, was decidedly faster than a Special Rapid developed with pyro and ammonia. Mr. Bennett promised to make further experiments before the next meeting, and specially to try to obtain greater density with amidol, expressing the opinion that this developer should be of great value for shutter work, where it was frequently necessary to give far less exposure than was desirable, even if the negatives had to be subsequently intensified.

Kensington and Bayswater Photographic Society.—November 21, the President (the Hon. L. M. St. Clair) presided.—A lantern lecture was given by Mr. C. DIXON on *Holland House*. The slides were taken from negatives made by the lecturer nineteen years ago by the wet-plate process. Their brilliancy compared very favourably with the more modern gelatine negatives. Mr. Dixon gave a description and history not only of the place itself, but also of its generations of inhabitants.

West Surrey Photographic Society.—November 16, Lantern Evening.—A collection of transparencies was passed through the lantern, explanations being given by Mr. DAVISON. The slides were contributed by Commander Gladstone, R.N., Messrs. T. W. Bright, H. L. Andrew Martin, Graham, A. R. Berry, F. W. Berry, J. S. Bond, and others. This proved to be the most successful public evening that the Society has ever held, and the Committee feel so much encouraged that they intend to continue the series of "free public" evenings at intervals during the winter months. The lantern was lent and worked by Mr. F. W. Berry.

Richmond Camera Club.—November 14, Mr. F. P. Cembrano, jun., in the chair. Mr. FAULKNER showed two prints on platinotype new paper which had been exposed to damp. One had been developed with glycerine in the developer; it turned partly red on development, but this redness, as well as some parts of the image, had disappeared on fixation. The other print, in the development of which the glycerine had been omitted, was of good quality, the deepest shadows being of a good rich black. Both pieces of paper, before exposure and development, had had the same opportunity of getting spoilt by moisture, and he could therefore not account for the great difference in the results. Mr. ANDASKER suggested that the piece that had become bad must have been outside the roll, and had therefore protected the second piece inside. Mr. GREEN wanted to know the simplest way of reducing whole plates to lantern size. Mr. WILLIAMS said he attached his camera to a baseboard, at the end of which he placed a box with an aperture in it to carry the negative to be reduced. The space between the negative and the camera he covered with a black cloth. To obtain the best results, reducing should be done by daylight. Mr. DAVIS had tried Mr. E. G. Richardson's system of using various strands of magnesium, and, although he had burnt as much as eight pieces, each one eight inches long, the transparencies were much under-exposed. The amount of smoke produced was so great that he had to clear out of his dark room after each exposure. Mr. CEMBRANO said that, with all its uncertainty, daylight was the best, as with artificial light it was difficult to obtain evenness in the lighting. For those that had no time during the day, he would recommend using smaller plates, and making slides therefrom by contact.

North Surrey Photographic Society.—November 15.—Mr. LEWIS WOLFF read a paper on *Development* (one of a series of lectures for beginners), in which he dealt only with the pyro-ammonia developer as being the one mostly in use, and which he believes to be still unrivalled. After giving a description of the uses of the components of the developer, and explaining how, by varying their proportions, developers may be compounded to meet the requirements of varying exposures and subjects, he developed two plates, the first being a properly exposed one, which yielded a good negative with a normal developer; the second, a plate which had received exactly four times the exposure of the other, but by greatly increasing the pyro and developing very slowly, using no alkali at the start, an equally good result was obtained, and it showed no trace of its having received so liberal an exposure. To give the beginners present a distinct idea of the functions of the chemicals used, he compared pyro to a horse, bromide to the reins, and ammonia to the whip.

Croydon Camera Club.—November 21, Lantern Night, the President (Mr. H. Maclean, F.G.S.) in the chair.—The attendance was good. Among the members present the following showed slides:—Messrs. B. Gay Wilkinson, C. Bray, H. Griffiths, H. E. Neeves, H. Maclean, A. Hirst, G. Corden, and A. E. Isaac (the last named also working the lantern).

Croydon Microscopical and Natural History Club (Photographic Section).—November 18, Lantern Night.—A large audience assembled to hear Mr. JOHN WEIR BROWN give an account of the Photographic Convention of last July, which he attended as a delegate, and large collections of views taken by himself and other members of the Convention during the various excursions were shown on the screen. Particularly noticeable were some fine architectural slides of Melrose Abbey, Abbotsford, and St. Andrews, and a series of hand-camera shots of fisher life in the little village of Newhaven.

Blackheath Camera Club.—November 15, Mr. G. S. Criswich in the chair.—A demonstration on *Lantern-slide Development* was given by Mr. J. T. FIELD (Vice-President). The demonstrator commenced by remarking that, in order to make a good lantern slide, you must first obtain a good negative, as it is useless expecting to get good slides from bad negatives. He printed and developed a few slides, using various brands of plates and the following developer:—A. Hydroquine, 160 grains; meta-bisulphite soda, 90 grains; potassium bromide, 20 grains; water, 20 ounces. B. Soda hydrate, 160 grains; water, 20 ounces. C. Soda carbonate, 2 ounces; potassium carbonate, 2 ounces; water, 20 ounces. Equal parts of A and B to produce slides with black tones, and equal parts of A and C for warm tones, with prolonged exposure, the proportions being modified according to time of exposure of slide, density or colour of negative, &c. He exposed by opening door of dark lamp and holding frame at a distance of one foot from gas flame. He pointed out that by exposing in this manner you can dispense with the back of printing frame, as no light can fall on the back of slide, and this is a great advantage when it is necessary to screen the light from any portion of the negative, as by looking through the back of the slide you can see exactly where the shadow of the screen falls. The fixing bath used contained four ounces of hypo and one ounce of soda bisulphite to twenty-five ounces of water, and was perfectly clear, though it had been in use for some weeks. He recommended the use of a clearing bath for lantern slides, especially when hard water had to be used for the other operations, the one he used himself being Edwards'. At a previous meeting of the Club, Mr. Hill had said that he was in the habit of developing isochromatic plates by yellow light, and to prove this he brought an exposed instantaneous isochromatic plate to the meeting, and developed it by the light of the Club dark lantern. This is a large gas lantern, with front and two sides formed with two thicknesses of yellow medium, the front having a light area of about two feet by one foot six inches, and sloping forward so as to throw the light down on to the developing dish, which was placed directly in front of the lamp and within a distance of three feet, thus forming a very severe test. The plate was developed, and proved to be a perfect negative without a trace of fog, though it had been once or twice held close up to the lamp for examination. This seems to prove that a deep ruby light, which is very unpleasant to work by, is not necessary for these plates; but, of course, care must be taken to prevent an undue amount of light from falling upon the plate before it is covered with the developer. There is much more danger of fogging the plate while transferring it from the slide to the dish and pouring on the developer than there is afterwards when the image has made its appearance. In this case the developer used was hydroquinone, which, when fresh, had only a very slightly non-actinic tint; with pyro and ammonia the plate would naturally be much more effectually protected. The next meeting of the Club will be held on November 29, when Mr. A. R. Dresser will give a demonstration on enlarging.

Aston Natural History and Photographic Society.—November 17, Lantern Exhibition by Mr. Townsend, of the Society, who gave his experiences of a photographic trip in the Channel Isles.—The slides were exceedingly good, and well merited the rounds of applause that greeted many of them. Mr. Tylar also showed some of his Swiss views, while other exhibitors were the President, Mr. J. W. Neville (who showed some magnificent hand-painted natural-history slides of his own production), Mr. Casson, jun., and Mr. Priddins.

Derby Photographic Society.—Mr. S. S. WATKINSON read a paper on Amateur Photography. The author disclaimed any intention to stand before the meeting as an authority on photography. The awkwardness of his position that evening was intensified by the fact that he had to speak before gentlemen who were recognised masters of the art, and, if photographic stature were taken into account, he was afraid they would require a powerful lens to discover him. The claims of photography, from an artistic point of view, were then considered. Some artists considered the death knell of fine art was sounded when the first photograph was produced, and that it was impossible to get true artistic results by means of such a mechanical science. In answer to this, the lecturer said that an ounce of proof was worth a ton of assertion, for the holders of palette and brush who practised the art of photography acknowledged their indebtedness to it, also that artists were often to be seen buying photographs of farmyard studies and broken pieces of foreground which are to be seen in shop windows. It was hardly fair to compare photography with painting; the latter was thousands of years old, while photography was still in knickerbockers, and photographers have every reason to believe—for there are many indications of it—that photography was on the eve of a greater development in the solving of the problem photography in natural colours. The lecture, which was much appreciated, led to a considerable amount of discussion at its close. Mr. Watkinson also passed round a number of pictures printed by various processes, those in platinotype being admired as giving the most artistic results. The SECRETARY announced that at the next meeting Mr. S. G. B. Wollaston, of London, would give a demonstration on the platinotype process. November 30, Captain Abney, R.E., F.R.S., would give a lecture on *Hand Cameras and Shutters*, illustrated with the lantern.

Newcastle and Northern Counties Photographic Association.—November 14,—exhibition of about two hundred lantern slides by local photographers and some of the best workers. There was a very large attendance, and the exhi-

bition was a great success. Altogether the slides formed a very fine series. There was a great number of local views, and these were all recognised and applauded. The exhibition is intended to be the first of a series, the next being announced for about a fortnight hence.

Photographic Society of Philadelphia.—October 12, the President (Mr. Joseph H. Burroughs) in the chair.—Mr. FREDERIC E. IVES read a paper on the *Heliochromoscope* (see page 758), exhibiting the apparatus, and also the special camera in which the negatives, with the necessary triple image taken through a single lens, were made. The wonderful results shown excited the highest admiration and favourable comment from the members present. Mr. FRANK S. LEWIS mentioned that, in developing film negatives lately, he had noticed that on lifting them out of the tray for examination, at the points where the back of the film rested on the fingers, the heat of his hand seemed to be communicated through the film so as to accelerate the development at those points. This was particularly noticeable in the skies of the negatives. He had also noticed that with some plates the strong contracting and adhesive power of the gelatine had caused it to pull off part of the outer surface of the glass around the edges of the plate. This seemed to be due to the glue-like character of the gelatine used, and illustrated the process largely used for producing a peculiar rough-surfaced glass for decorative purposes. A member asked why, in the case of an interior view, which had an hour and a half exposure, a streak of sunlight, which could be assumed to be greatly over-exposed, had developed intensely black instead of giving the thin image generally resulting from over-exposure. Dr. MITCHELL thought it came from a second reversal of the image at that point, the usual thin image of over-exposure being again reversed and showing black. Mr. C. W. MILLER said that, if an over-exposed negative were developed long enough, it would become black all through, as with the streak of sunlight. But, usually with such negatives, they were soon found to be over-exposed, and the developer modified accordingly, the development being stopped before intense blackness was reached. A member stated that in photographing in Florida, the Yellowstone Park, and other places where the sky was intensely bright, the skies were almost always over-timed and thin, and asked for a remedy. Dr. MITCHELL suggested holding the sky back with a colour screen and orthochromatic plates. Mr. CARBUTT recommended washing the plate off when the sky had reached the proper intensity in developing, and then, with a tuft of cotton or soft brush, continuing to apply the developer to the foreground until a harmonious result was obtained. Mr. IVES practised another method, which was to reduce the over-developed portion of the negative with Farmer's solution, applied in a similar manner to that recommended by Mr. Carbutt. This he did after fixing, and in daylight, which was quite an advantage. Dr. MITCHELL spoke in high terms of some interior views in the Alhambra, taken by Mr. Cembrano, Secretary of the late Photographic Convention, held in Edinburgh. These pictures had the strongest possible contrasts of light and shade, and he understood they had been developed on the plan described by Mr. Carbutt.

Photographic Society of Japan.—October 7, Mr. Edmond R. Holmes in the chair.—The new concentric lens of Messrs. Ross & Co. was shown by Mr. W. K. Burton, along with work done by it, and by other wide-angle lenses of the same focal length. The new lens did not give absolute definition with the maximum aperture of *f*-16, but it gave exactly the same definition at the edge as at the centre of a fairly large-sized plate. With an aperture of *f*-22 it gave absolute sharpness very nearly to the edge of a plate 22×12, the lens being twelve inches focus, and a flat object at right angles to the axis of the lens being focussed. In fact, the field was truly flat, and this was the first lens of which such a statement could be made. A universal lens by the same firm was also shown. This was of the type of the rapid symmetrical, but was twice as rapid. It was an outcome of the new Jena optical glass. Mr. K. Ogawa, as well as Mr. Burton spoke of its high qualities as a portrait lens. The Foreign Secretary had been asked to report on a sample of Mr. J. B. Obernetter's plates. He had found them very rapid, although not quite up to the rapidity of the most sensitive plates in the market in Japan, and of exceptionally good quality. A very ingenious portable metal tripod stand, each leg going into a small tin box less than three inches long, was presented to the Society by Mr. R. Mitomo. A set of small prints on bromide paper was shown by Mr. K. Arito, and were much admired.

HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The medal in the landscape class of this Exhibition, awarded to Mr. Austin, was a bronze, not silver.

Correspondence.

PHOTOGRAPHIC PRIVILEGES AT THE PARIS EXHIBITION.

To the EDITOR.

SIR,—I see that a correspondent inquires for the address "of the firm who had control of the photographic privileges in the Paris Exhibition." The "photographic privileges" were not under the control of any firm. The Executive kept the managements in their own hands, and made a certain charge—I forget the amount—to anybody who desired to take photographs in the Exhibition. The permission thus granted did not include the right to photograph exhibitors' stands.—I am, yours, &c.,

H. T. WOOD.

Society of Arts, John-street, Adelphi, London, W.C., November 20, 1892.

THE MADDOX TESTIMONIAL FUND.

To the EDITOR.

SIR,—Having very lately received the promised and highly-valued Testimonial from the Hon. Secretary to the London Committee (Mr. Andrew Pringle), may I solicit the favour to offer through your pages to each of the signatories the expression of my highest and deepest obligation, at the same time that I present my sincerest thanks to the members of the Foreign Committee and their Hon. Secretary, Mr. C. J. Sharp.

I also beg to tender my fullest acknowledgments to the Editors of the foreign journals who have so kindly given their assistance, and likewise to express to the members of those Societies, who have so graciously affiliated me as an honorary member, my highest esteem for such distinguished honour.

To the contributors to the Funds, both at home and abroad, I beg to offer every expression of gratitude on the part of myself and family, and to state that the amounts have been duly invested for our mutual benefit. The foregoing will, I trust, be accepted as a faint testimony to my indebtedness, and the sincerity of my expressions.—I am, yours, &c.,

November 18, 1892. R. L. MADDOX.

To the EDITOR.

SIR,—Will you kindly do me the favour to insert in your next issue the enclosed list of the amounts received in connexion with the Maddox Foreign Fund, which is now closed, and, through your columns, permit me to express the thanks of the members of the Foreign Committee for the kind support given to their appeal.

The amounts have been duly handed to Dr. Maddox for investment, and, I am sure, have been highly appreciated by him. Please accept the thanks in advance of—Yours, &c., CHARLES J. SHARP, *Hon. Sec.*

MR. BHEDWAR'S PICTURES.

To the EDITOR.

SIR,—I really cannot enter into a discussion in this matter. I believe the editor of a paper is generally considered responsible for the accuracy of contributions accepted from anonymous correspondentcies. It is for you to propound a theory to account for the erroneous suppositions printed in your paper about Mr. Bhedwar's intentions. Having told you Mr. Bhedwar's instructions to me were not to send his pictures to Pall Mall,

it seemed unnecessary to add the fact that entries closed for the exhibition in question before the pictures arrived in England. Mr. Bhedwar has sent a letter to your contemporary in which this question was first brought up, explaining his intentions, a copy of which I have received since writing the above. I find it renders any explanation from me quite unnecessary.—I am, yours, &c., RALPH W. ROBINSON.

Redhill, November 17, 1892.

To the EDITOR.

SIR,—As Mr. Ralph Robinson's statement that Mr. Bhedwar has resigned his membership of this Society, "although, being a foreign member, he had nothing to pay for the privilege," is not quite correct, and is likely to lead to unnecessary correspondence, I shall be glad of the opportunity of saying that foreign members pay exactly the same subscription to this Society as other ordinary members. A member can, if he chooses, when going abroad, have his name transferred to the "non-resident" list and cease his subscriptions, but he then forfeits all the privileges of membership. The only advantage remaining to him is that he can resume these privileges at any time by resuming his subscriptions, without the payment of another entrance fee. Mr. Bhedwar's resignation has nothing to do with anything whatever except his leaving this country. —I am, yours, &c., CHAPMAN JONES,

11, *Eaton-rise, Ealing, W., Hon. Sec., Photographic Society of*
November 19, 1892. *Great Britain.*

THE PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

To the EDITOR.

SIR,—Will you kindly announce to your readers that the sixth annual Exhibition of Photographs, open to all photographers of the world, under agreement between the Photographic Society of Philadelphia, the Society of Amateur Photographers of New York, and the Boston Camera Club, will be held by the Photographic Society of Philadelphia, April 17 to 29, 1893.

It is hoped that with this early announcement we may be favoured with liberal exhibits from foreign photographers, to whom special inducements and facilities will be offered. Circulars, with rules and full particulars will be issued early in December, and may be obtained on application to the undersigned.—Very truly yours,

ROBERT S. REDFIELD, *Chairman Exhibition Committee.*
1601 *Callowhill-street, Philadelphia,*
Pennsylvania, U.S.A., November 11*th*, 1892.

P.S.—Exhibits should be made ready to forward at earliest possible date, as considerable time will necessarily be consumed in transit, &c. They will be required to arrive in Philadelphia probably about March 15.

THE LEYTONSTONE EXHIBITION.

To the EDITOR.

SIR,—May I venture to ask you to kindly allow me, through your columns and on behalf of the Leytonstone Camera Club, to thank those numerous ladies and gentlemen who sent pictures to our exhibition, and we assure them that their general excellence was duly appreciated by the hundreds of spectators who thronged the halls. The vast number of exhibitors render it impossible to thank each person individually; moreover, its unprecedented and unexpected success has given me so much extra work that any little failing on my part as to prompt answering of the numerous letters that I have received, and other shortcomings, will, I trust, be excused. Once more sincerely thanking one and all who contributed to one of the most successful local exhibitions that has yet been held,—I am, yours, &c., ALBERT E. BAILEY, *Hon. Sec. Ex. Com.*

Rose Bank, South-West-road, Leytonstone.

ARTIFICIAL ILLUMINATION.

To the EDITOR.

SIR,—In your article on this subject, you refer to a method brought by myself and another before the members of the Liverpool Amateur Photographic Association, and you remark as to the danger in handling the light-giving sheets, especially when cutting to size, on account of the explosive nature of the compound of magnesium and chlorate of potash, and also, as to the difficulties when covering large areas.

I shall esteem it a favour if you will allow me to say a few words on these points.

In the first place, in dividing the larger sheets care would be taken to avoid the "pellets" of magnesium, &c.; and as these, in actual practice, are separated by nearly half an inch, in each and every direction, little difficulty would be experienced. In the second place, I am somewhat doubtful of the explosive properties of the compound as alleged, having failed after numerous trials and experiments in producing an explosion by *friction* of any description, and emboldened by my non-success in this direction, having submitted it to tests of the severest description with the object of producing, but without experiencing any sign of an explosion.

The anticipated difficulties attending the lighting of large surfaces will be found to exist only in anticipation, as the sheet can be ignited when in actual contact with a supporting piece of wood, and is in fact at its best when so used.

The method will be found in practice to be economical, the preparation of the pyroxyline paper being the most troublesome part of the whole process, but doubtless it can be purchased, ready made, at a reasonable rate.

Thanking you, in anticipation, for the space afforded,—I am, yours &c.,
C. B. READER.

Mountside, New Brighton, Liverpool, November 16, 1892.

PHOTOGRAPHIC CLUB.—November 30, Monthly Lantern Meeting. December 7, *Retouching*, by Mr. Redmond Barrett.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—December 1, Special Lantern Exhibition of *Scenes from Ireland*, by Mr. F. W. Hindley. Visitors welcome. 8, Members' Open Night.

APROPOS of "B Z's" verses, a correspondent writes:—

When "*Welcome*" is written to rhyme with "*Music*,"
The rhyme is enough to make me and you sick.

MR. DAVID RAMSAY, of the Heliotype Printing Works, Boston, has, we hear, died at Liverpool while on his way to Glasgow, his native city, for a visit. He was a well-known Scots-American of considerable ability in his business of collotype printing.

A SMART bit of work was performed at the Hackney Photographic Exhibition on Thursday week. Among the exhibits of apparatus, &c., were the Platinotype Company's new lamp for printing at night, and the Paget Prize Plate Company's new printing-out lantern plate. A negative of the Secretary was obtained, and with the above-mentioned articles a lantern slide was printed and thrown upon the screen, *the whole operation not requiring more than* 120 *seconds.*

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

G. W. Webster, Chester.—*Photograph of a bunch of grapes.*
Mackintosh & Co., Kelso.—*Portrait of the Duchess of Roxburghe.*
John Robertson, Dundee.—*Two photographs of the Rev. James Aitken.*

INQUIRER.—The reason given is that if the films were issued in larger sizes, they would not lie quite flat.

G. W. RAMSEY.—Your local gasfitter will be the better able to assist you in regard to the practical details.

H. L.—Write to the two makers named for their catalogues, which will give you all the information required.

W. HUTCHER & SON (Blackheath) send us their catalogue of lantern requisites, flash-lamps, cameras, dry plates, &c.

REV. GEO. ROLLINSON.—You will find in the present issue an article on amidol which quite answers your various queries. It will be useful to amateurs.

C. LUX.—From the description of the behaviour of the light, we surmise that the orifice of the oxygen jet has been injured in transit. Better return it to the maker for examination.

CARBON.—The best waxing solution for glass plates in the carbon process is made by dissolving five grains of beeswax in each ounce of benzol. It is imperative that both materials be pure.

FLASHLIGHT.—The oxyhydrogen light could be used for portraiture, but a quick-acting lens and very rapid plates would have to be used, otherwise the exposure would be a very prolonged one.

J. FOSTER.—An ordinary cabinet portrait lens will best serve your purpose, for by it either a *carte* or a cabinet may be taken. You might write to some maker or dealer, and obtain one on trial.

A. H. H.—There may be several reasons; but, if the same materials be used, the difference must be due in some way or other to the manipulations. In what way, it is, of course, impossible for us to say.

LEEDS.—Without knowing the amount of chloride with which the albumen is salted, and other conditions, it is impossible to say the amount of silver that each sheet will contain. The value of residues cannot be estimated from any such data as that.

T. REYNOLDS.—The iridescent markings round the edges of the negatives show that the plates were old stock or, at least, had been made some time. As the plates were not had direct from the makers, better communicate with those who supplied them.

TRIPOD.—We think your charges are exceedingly moderate. Most photographers would have charged both a higher fee and also travelling expenses.

S. L.—The loss of brilliancy in the lights of the prints is caused not by the time they were in toning, but by their being exposed to too strong a light during the operation. One hour, in even feeble daylight, will have its effect, as the result proves.

J. KERSHAW.—We should prefer the arrangement of blinds shown in sketch No. 2 to that of No. 1. Place the sitter in such a position that the side light is utilised as much as possible. If the side light can be enlarged, or, better still, extended to the top light, you will then have an excellent studio.

A. W. J.—As the man is dead, you must look to his executors for payment of your account. As the last order was ready for delivery at the time of death, the account for that must be included with the other. The goods, however, should have been delivered as soon as they were ready. The executors may now refuse to receive them.

DARK SLIDE says: "I am making a set of slides to go abroad; these are on gelatine plates. Would you recommend varnishing or not, and if to be varnished mention a suitable one? Climate is hot, and at certain times of year very damp."—Varnish the slides with celluloid in solution of amyl-acetate. Varnishes of this nature are on the market.

BRIGHTON.—1. Zinc or tin cans are quite unsuitable for keeping a stock of hyposulphite of soda solution in. For such a purpose metal vessels should never be employed. 2. See answer to "Printer." 3. From forty-five to sixty grains of nitrate of silver to the ounce of water is a good strength for the general run of papers. Some papers work better with a weak bath than others.

H. PRICE.—We fear the steps you are taking to increase the permanence of the prints will have just the contrary effect. Twenty-four hours' washing will certainly act injuriously. The shorter the time of washing, so long as the hyposulphites are removed, the better it is for the permanence of the picture. With perfect fixing, prints, with attention, can be perfectly washed in two or three hours.

H. C. (M.D.)—1. There is no patent in the mere use of changing-bags, although there may be in methods of using them. The idea of the bags themselves was made a present of to the public by G. V. J. Poirin, through our ALMANAC for 1885, page 140. 2. Numerous shutters work on the curtain form propelled by a rubber spring. Are you not mistaken in supposing this to have been patented?

M. A.—If the pictures sent are a fair sample of the lot, we fear there is very little prospect of selling the negatives to any of the publishing houses. The photographs are good, and the subjects well chosen, but they are of no interest. Country lanes in one part of the country are very much like those in another. Publishers value negatives according to the interest attached to the subject and locality.

TYRO.—1. There is such a degree of similarity among the productions of the various makers mentioned that you need have no hesitation in taking any of them, irrespective of price. 2. Iris diaphragms are certainly convenient, but are by no means necessities. Had you mentioned the focus of the single lens, which covers your half-plate sharply with *f*-16, we could possibly have deduced its value better.

H. B. C.—We should say that a whole-plate camera with three double slides with the usual etceteras is more than a lady can conveniently carry without assistance, unless she is blessed with greater physique than are most of the fair sex. By dispensing with glass and taking films the weight would be considerably reduced. Even then, we fancy, the kit would prove very fatigning on a hot day.

S. A. R. says: "I have read that gold can be recovered from old toning baths by precipitating it with a solution of sulphate of iron. I have tried this with two exhausted acetate baths, and I find nothing is precipitated. Can you explain the reason?"—If no precipitate is thrown down by the iron, it is clear that there is no gold in the solution. If the whole of the gold is used up in toning prints, none remains to be recovered.

W. RAY writes: "The lead sink of my dark room which has been in use for several years is now worn out and has to be replaced. Do you think there is any silver in it? The lead at the bottom has a thick coating upon it which I think must contain some silver. It was used in the old wet-plate days, when more silver was used than now."—It is very unlikely that there is any silver present, or, if there is, not in sufficient quantity to pay for separating from the lead.

R. WINCH asks how he can produce a very intense degree of cold by the admixture of any chemicals which are easily procurable.—If he examines our ALMANAC for 1893, which will be published in a fortnight, he will see much that may interest him on this topic. But in the meantime, he may try the following mixture:—Crushed ice, 12 parts; chloride of sodium, 5 parts; nitrate of ammonia, 5 parts. This is said to produce an intensity of cold equalling twenty-five degrees below zero.

THOS. BATES sends a photograph, a group of several persons taken by flash-light, and asks why the majority of the faces are so black, while a few are very much better. The reason is that the picture is under-exposed generally. The few figures in the foreground, and nearest to the source of illumination, are better exposed than those further behind. Had the group been better arranged so that the illumination would have been more even, and more magnesium used, the result would have been widely different.

PYRO.—It is not usual for platemakers to replace plates broken in transit. Nor could they reasonably be expected to do so under the circumstances detailed. As the packing-case was a strong one, and duly labelled "Glass," it should not have been accepted from the railway company, and signed for, if it were "completely smashed." The company would then have made compensation. The only thing now is to proceed against the railway company in the County Court, but the result will be very doubtful.

VADZE.—Apply to Hughes & Kimber, Fetter-lane, or Winstone, Shoe-lane. Either firm supply material for process work. See answer to J. Gascoine. We do not know of such a work as that mentioned.

B. R. writes: "What plates and what lenses are used for taking pictures by moonlight, such as are sometimes shown in the shop windows? Some time ago I exposed two extra rapid plates with a rapid rectilinear lens, full opening, one for twenty minutes and the other for half an hour, and did not get an image although the moon was at its full."—The so-called moonlight pictures are in reality taken in sunlight, the negative being much under-exposed. The best effects are obtained by taking the picture when the sun is near the horizon.

MIRROR asks: "Mirror to be fixed outside for enlarging. Will the common thin kind do, not plate? It will probably answer as well for reflecting, but the plate glass may be better prepared for standing wear. What is the best way of attaching to frame? Should it have something soft between the glass and wood, or not be in contact all over, and should back of mirror be painted over with anything? The wooden frame must be shut up when not in use; too many boys throwing stones about to leave permanently at an angle."—A piece of silvered glass, common or plain, will answer; the latter for choice. It will not require "backing." Place it in an ordinary wooden frame.

PRINTER writes: "Could you kindly tell me the cause of the spots on the few proofs I have enclosed? I have never seen such things before. I may say it is a fresh lot of paper just started; the old paper worked very well on a fifty-five grain bath, and this paper went well the first day on the same bath, but the second day these spots appeared. I thought first the bath was a bit strong; and reduced it, but the spots were the same. I concluded something had got into the bath. I made a forty grain fresh bath; the spots are gone, but I fail to find the cause of the spots. Can you give any opinion as to the cause in the column of 'Answers to Correspondents?'"—The cause of the spots, or rather mealiness, is that the first bath was too weak. If it was originally fifty-five grains to the ounce, it had clearly become much weaker by use. Make it up to its original strength and it will again work all right.

F ♯ SHAKES HANDS WITH B ♮.

"THREE cheers for our good President—and Art,"
And three times three for Secretary D;
There lives no man could play the Hon. Sec.'s part
So well as he has done for you and me.

Your hand I grip, B nat., whoe'er you are.
You love the pathos of the minor key,
And so do I. I'll even go as far
To say, I like some works of our G. D.

It is not we, the "majors," who have said
All work is bad except the work we do;
It is the "miners" only who have laid
That unjust veto on the good and true.

B natural, be fair, be honest, and be kind!
Confess there are no "rival styles." Apart
From what you think, you'll one day find
The True alone is beautiful in Art.

F ♯.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1700. Vol. XXXIX.—DECEMBER 2, 1892.

COLD AS A CAUSE OF STAINED PRINTS.

Not unfrequently, when winter has set in, do we have complaints, more or less numerous, of stains appearing on prints even when a strict adhesion to formulæ successfully worked all the summer is maintained. These complaints do not emanate exclusively from photographers whose experience may be assumed to be limited, but occasionally are made by some of long standing, and the excellence of whose work otherwise has never been challenged.

The stains in question sometimes appear immediately after the prints are finished, while, on the other hand, one or more weeks may elapse ere they are perceptible, merging from a faint yellow into one of very pronounced colour, with a considerable degree of rapidity.

There is a well-known axiom to the effect that all chemical action is aided by heat, and it applies to the case before us. We have many times found by actual experiment that a solution of hyposulphite of soda of a strength quite sufficient to dissolve out of the print the hyposulphite of silver which is produced as the first action of the fixing bath on the chloride, when the solution is between 50° or 60° Fahr., fails to do so when cooled down to the temperature of the atmosphere during a cold winter day.

From this it follows that temperature forms a powerful factor in the fixing of a print, and points to the reason why a fixing and toning formula that works well in the summer may not do so in winter, unless, of course, the precaution is taken to have the fixing solution made warm or brought up to summer temperature. We may here repeat what we have formerly written, that when crystals of hyposulphite of soda are added to water to be dissolved, no matter what the temperature of the liquid is at the time, the mere addition of the crystals will cause it to fall to a considerable extent. This is easily shown by placing a thermometer in a vessel, such as a glass tumbler, of water, and, having first noted the temperature, throwing in a few crushed lumps of the soda and watching the rapid descent of the mercury in the tube. There are many frigorific salts that lower the temperature to a much greater extent than hyposulphite of soda, for example, nitrate of ammonia; but hypo does it to an extent sufficient to interfere with its property of being a fixing agent.

The obvious moral to be deduced from this is not to employ freshly made fixing bath until either by standing for a little time or by the addition of a little hot water, or by any other means whatever, its temperature shall have been raised to a point sufficiently high to ensure its not failing to do the work that is required of it. When a solution is kept ready made up, its temperature will not descend below that of the room in which it is kept; but under no circumstances ought it to be very cold when being used, otherwise may the prints suffer from imperfect fixation.

EXPOSURE AND DENSITY.

At a recent meeting of the Photographic Society of Philadelphia, reported in our last issue, two questions were discussed, which, although they appear to have cropped up independently of one another, bear a strong resemblance. In the first case a member asked why, in a negative of an interior which had received a very long exposure, a streak of sunlight, which might be presumed to be much over-exposed, appeared perfectly opaque in the negative instead of giving the thin image usually resulting from over-exposure.

One of the replies suggested that the result was due to a second reversal of the image, while another member pointed out that an over-exposed image, if developed long enough, would usually assume the dense appearance of the streak of sunlight.

The second question was as to a remedy for the thinness in the skies of negatives exposed in certain localities where the sky was intensely bright, the thinness being set down to over-exposure; in fact, a diametrically opposite effect from that complained of from the same cause in the previous question. In this instance, if the proceedings are correctly reported, with the exception of a reference to the use of orthochromatic plates and the colour screen, the remedies proposed seem to be more calculated to meet the difficulty of over-dense skies than of thin ones. However, the apparent anomaly between the two cases is worthy of a moment's discussion.

First, with regard to the suggestion of a second reversal of the image in the case of the dense sun-streak, we may say at once that we consider it directly against all experience that the image of second reversal should be stronger than the original, or what the original one might be supposed to be if in due gradation to the rest of the picture. In all the experiments we remember to have seen reported, in each successive reversal the image became weaker; in fact, after the first reversal the results have been of such a nature as to leave it doubtful whether repeated reversals really occur or not.

Further, it may be urged against this solution of the question that, in order to produce a second reversal, a much more powerful light would be required than that reflected from a streak of sunshine striking an interior wall. In the case of sunshine, or even strong diffused light, falling directly upon the lens from an open window, the case would be widely different, and then we might expect, if not a second reversal, at any rate a partial first reversal, which would produce the same

effect, namely, an image of the window thinner than it should be.

We had a negative taken in the early days of gelatine plates which clearly demonstrated the difference between the effects of over-exposure in the case of direct and reflected light. It was a church interior, and included a window through which the sun was shining, though not directly into the camera, though two or three streaks or "splashes" fell upon one side of the chancel wall. The window was—to use the expressive term then in vogue—"burnt up," being thin and transparent, with every detail of the tracery entirely lost in "halation;" the splashes and streaks of sunlight were dense almost to opacity, while the remaining details of the picture were of the average vigour of such subjects, perhaps rather thin than otherwise.

This bears out the second explanation—or partly so, we think—that the extra density was due to the long continuance of development, so far, at least, as the sun streak was concerned; but the same argument would not hold good, perhaps, with regard to the window. In other words, the statement that "if an over-exposed negative were developed long enough it would become black all through" may be true enough of a comparatively slight over-exposure, but not so where the excess of exposure has been very great. Besides this, we may add that much will depend upon the character of the plate in use, as we shall endeavour to show.

Let us go to ordinary every-day development to help us to explain. Take the case of ordinary over-exposure first; be it in portrait or landscape work, we get a thin delicate image varying in its thinness and general flatness with the degree of over-exposure. We get this result simply because—restrainers failing to keep the shadows clear—we are obliged to arrest development before a sufficient reduction has taken place to produce density; but, if we leave that plate in the developer for a few minutes longer regardless of shadows, the result will be an equally flat image, dense in the lights and filled up in the shadows, and equally devoid of contrast with its earlier stage, only requiring a much longer time to print. Turn to an under-exposed plate and we find that the high lights develop up with, perhaps, ordinary rapidity, but we have to force development to get out the details. By careful coaxing we may probably succeed at last; but while we have been giving strength to the more feebly illuminated portions of the image the same process has been going on in the high lights, until these have become dense beyond all printing utility.

Here we have the true explanation, we think, of the dense sun streak alluded to in the question, but when it comes to the matter of reversal the circumstances are quite different. In a case of real reversal, that is to say, the production of a positive image where a negative should have been, the first effect is a very faint fogging or reduction, where the excess of light has acted, and then other portions of the image which have received less light begin to appear, and rapidly leave the over exposed portion behind in the matter of density. Indeed it seems impossible by any prolongation of the time of development, or any modification of the solution, to add anything to the slight reduction first produced.

Where the reversal is only partial, or, we may say, where it is only commencing, the reduction takes place rapidly at first, as in all cases of over-exposure, but is suddenly arrested when a certain density is attained, and beyond this point it steadfastly refuses to go. This seems to be the proper explanation of the thin skies referred to in the second question, and to the transparent patternless windows so frequently found in negatives of interiors.

We have said that much will depend upon the character of the plate employed. For instance, a dense, thickly coated plate will lend itself more readily to the production of opaque images from over-exposure than one that is thinly coated or on which the particles of silver bromide are coarse and the transmitted colour blue. In the first place, the thickly coated plate has more material upon which the developer can work to produce density, while its inherent opacity tends to restrict the action of the light to its surface, or at least to partially arrest its penetration. In the thin, transparent film there is, perhaps, not silver enough to give great density under any circumstances, while what there is is subjected to a far more searching action of the light, and so placed in a far more favourable condition for reversal.

Some years ago we made duplicate exposures in one of our English cathedrals with two different brands of plates we had with us. As regards rapidity there was little if anything to choose between them but in physical characteristics one; was robust and opaque, while the other was of the blue and granular type. The first gave us almost complete opacity in the windows, with a total loss of the mullions and tracery from halation, while in the second a plain semi-transparent blank was all that told where the windows should have been. So far as the remainder of the pictures was concerned, the one plate behaved as well as the other.

Another instance recalls itself of difference of behaviour under precisely similar circumstances. In looking over a large number of negatives taken by the late Colonel Stuart Wortley in Tahiti, many of which were exposed directly in the face of the sun, we noticed that, while in some the sun's disc was represented as a sharply defined opaque circle, in others it showed a transparent circle with a softened edge. On remarking on this circumstance to Colonel Wortley, he stated that it was simply a difference in the brand of plates, and pointed out two which had been exposed within a few minutes of one another under exactly similar conditions and in one of which the sun was transparent and the other opaque.

It may be interesting to some of our readers to note, in conclusion, that where over-density follows excessive exposure there are several ways in which it can be reduced so as to bring the defective part into harmony with the rest of the picture. And further, where the over-dense portion is a church window, or similar object, although all detail of the tracery may be apparently lost, careful reduction will usually restore it. We have frequently, and with perfect success, treated such subjects by carefully rubbing down the defective portions with a tuft of cotton wool impregnated with alcohol, and so restored the most delicate details; while other operators use finely powdered pumice in the same manner. No doubt the usual reducing solutions would answer as well, though we have not tried them.

The image that suffers from incipient reversal is, however, beyond all treatment.

PHOTOGRAVURE IN AMERICA.

In the last issue of the *Journal of the Franklin Institute* is a paper on "A New Intaglio Process," that was read at a recent meeting of the Institute (see page 757 of our last issue). We should not have reprinted the paper were it not that it contained several misapprehensions as to the later phases of photogravure, which it is desirable to correct. In the paper the author embraces the opportunity to decry the processes now in vogue,

and their alleged shortcomings, in enhancement of his own, of which, by the way, he gives no details, and, in doing so, he displays a considerable degree of ignorance of what is going on in the matter of photographic engraving on this side of the Atlantic. The new process is named photo-mezzotint, as the inventor says, not because it is the most exact term to denote it by, "but because all the other good names have already been pre-empted, and made to do service in other directions." If we mistake not, this name, too, has long since been in use in connexion with mechanical photography in this country.

It is only in one short paragraph that the new process is alluded to, and there it is mentioned that the principal feature of it lies in the picture, instead of being obtained from a graduated depth of engraving, as in the case of the ordinary photo-engraved intaglio plates; it is produced from a sunken surface of uniform depth, the graduations from light to shade being secured by minute lines and stipples of varying thickness, but of a uniform distance from centre to centre. So far, according to what the inventor says, the new method would appear to resemble the system adopted for obtaining half-tone relief "process blocks." We are told that the half-tones of the new method consist of stipples of about 44,000 to the square inch. Beyond this no further details are given, but many claims are made for the superiority of the new method over all others. Indeed, the paper, except that it appears in the journal of a scientific society, reads very much like an advertisement, particularly when the final sentence is reached, in which it is intimated by the inventor, Mr. Louis E. Levy, that the process has been made the subject of an application for letters patent.

It is mentioned above that the author of the paper exhibits a great want of knowledge of what is being done out of America; he also shows an equal want of knowledge of the technics of the different processes to which he refers. This will be particularly noted in the second paragraph of the article, in which it is stated, referring to the usual methods of working, that the unaffected and unreduced portions of the exposed bichromated gelatine film are dissolved and washed out, and the film then dried. "In this condition it may be printed from direct, or it may be used as a mould to produce a reverse—several well-known methods of moulding being given—from which, in turn, a reverse can be made by casting or electrotyping." It is certainly a novelty to be told that a dried gelatine film can be printed from as an intaglio copper plate.

There is another portion of the paper to which we must take exception. After alluding to the difficulties in, and the great skill required in working, the present methods of producing intaglio plates, and that on this account the work is practised but by few, and then only by such as possess artistic capacity and training, the following statement is made:—"In only one establishment, and that in Paris, has the work been brought to a high degree of quality, and there, as well as in other workshops, the hand of the skilful retoucher is frequently to be credited with the largest share in the final result." It may be correct to say that America—although well to the fore in process blocks—is behind Europe in the matter of intaglio work of the highest order, such as the large photogravure reproductions of works of fine art; but it is certainly not the case that in only one establishment, and that in Paris, the work has been brought to a high state of perfection, or that the greater part of that perfection is due to hand work on the plate. As a matter of fact, quite as good, if not better, work of this class is now being produced in Berlin, Munich, Vienna, and other Continental cities, and also in London, as in Paris, and, in the case of Germany and Austria, with, as a rule, less hand work upon it. Furthermore, high-class photogravure is practised by more than one firm, even in Paris.

It is alleged also that the present methods of photographic engraving are exceedingly difficult, and require great skill to work them. They, like all other work, require a certain amount of practice before proficiency is attained; yet not more than is requisite in almost every other process, whether connected with the arts or manufactures; but with the new process it is implied that this will be unnecessary. Again, with regard to hand work upon the plates, at one time, it must be admitted, the high quality of many plates was, to a considerable extent, due to the work of skilled engravers; for some time, this has not been the case. Many of the best Continental photogravures are very little indebted to the engraver for their excellence; indeed, it is surprising how very little hand work there is upon them at the present time. This is in a great measure due to the recent photographic improvement in translating the colours of the original painting into monochrome. Formerly this had to be done by skilled engravers on the copper plate, but this has not been the case of late years.

As previously implied, the reason we have alluded to this portion of the paper is that many who are not familiar with modern intaglio work might be misled as to the present state of the art on this side of the Atlantic. However, we look forward with interest to the new process so freely extolled by its inventor.

The Proposed New Photographic Institution.—Much curiosity has been excited as to the progress of the movement for the establishment of a new photographic society or institution on somewhat original and comprehensive lines, to which we referred a fortnight ago. So far as we have been able to gather, while nothing of a definitive nature has been decided upon, considerable preliminary discussion and consideration of the principal outlines of the scheme have taken place among the promoters of the idea (which includes some of the foremost men in London photographic circles), and we have the best reason to expect that an announcement on the subject will shortly be made. For the rest, we may be permitted to express the belief that, when the scheme is put before the photographic public, it will be found to be conceived upon a thoroughly catholic and representative basis.

The New Comet.—There does not appear to be much probability of Holmes' comet being of great photographic interest, for already, though its size has increased, its brightness has decreased. Most observers describe the new planet as having no tail, though one gentleman, writing to the *English Mechanic*, states that it possessed, when he saw it, a tail several times longer than the comet itself.

Shooting Stars and Photography.—In connexion with this and other comets there have been several recommendations to observers to keep a brisk look-out for shooting stars, November, under ordinary conditions, generally affording a plentiful crop. Our present purpose in writing is to suggest that photographers possessed of only an ordinary camera and lens—say, for ten-inch plates—could do very useful work on the occasion of an expected star shower. Pointing the camera at the region indicated, and changing the plates—say, every five, ten, or fifteen minutes, accurately recording the time—the errant stars would record themselves, and such plates taken by a number of observers throughout the country would give a mass of information of most useful character, that would enable a very fair parallax to be obtained and serve to give the actual distance of these bodies from the earth within narrow limits.

The 1893 Convention.—It will be seen by the society news in the current number of the JOURNAL that the Devon and Cornwall

Camera Club, of Plymouth, the issuers to the Photographic Convention of the United Kingdom of the invitation to meet at the town named next year, propose at their next meeting to exhibit a series of slides of places to be visited by the Convention in 1893. The slides are afterwards to be loaned to other societies. We are happy to find, from this and other evidences, that the Club is taking so keen an nterest in the auccess of the Convention, which will be assured if the same enlightened course of giving it publicity be pursued during the coming months.

To Keep Iron and Steel from Rusting. — The number of articles in photographic use constructed from iron and steel, from rolling presses and head rests downwards, will render serviceable a couple of recipes, adapted for the purpose in other directions, which we append. One of the simplest, and which has been in use for many years, consists in coating the article with a solution of india rubber in benzol made of about the consistency of cream. It may be applied with a brush, is easily rubbed off when needed, and effectually prevents rust. A coating of more use where the "tooth" imparted by rubber would be disadvantageous, is prepared in the following way: Dissolve two parts of crystals of chloride of iron, two of antimony chloride, and one of tannin in four of water. Apply with a sponge or rag and allow to dry. A second or third coating, or more, is given in the same way that a dark colour is produced. When dry, it is washed with water, again allowed to dry, and polished with linseed oil. The antimony solution should be as nearly neutral as possible.

Photography and the Dead.—The remarks of our contributor "Cosmos" in last week's JOURNAL, referring to the publi cation of sketches from photographs of the bodies of some of those drowned in the *Roumania*, draws attention to an occasional abuse of photography. There can be no possible objection to the photographing of persons who have died from accident provided that it be done under official surveillance, and the negatives and prints retained in official custody, but when they are passed from hand to hand and published they are calculated to shock one's susceptibilities, and to give pain to the friends of the deceased. At the time of the Whitechapel murders we were aware that photographs of the remains of one of the victims were being handed about as curiosities. Such proceedings should be impossible with proper official precautions. It is bad enough for the hand camera to bring photography into disrepute by its often impertinent use, without pictures of the dead being taken and published, in defiance of all right feelings for the departed, to cast still further disrepute upon it.

An Exhibition in Japan.—Messrs. George Davison and Andrew Pringle have received through Professor W. K. Burton an invitation to English photographers to contribute to an exhibition to be organized by the Photographic Society of Japan at Tokio early next year. In a letter to the two gentlemen named, Professor Burton says:—"I should think the exhibitors would be curious to see what is the standard of taste over here. I presume you know that it is much higher and more refined than in Europe. I could readily get, say three, of the best artists to act. They would know nothing of the names of the exhibitors, or of their previous record, so that the judging would, at least, be absolutely without bias of any kind." The following are the instructions which Messrs. Davison and Pringle deem necessary for intending exhibitors:—The photographs need not all be of recent date. They will be new in Japan. Please send the best you have at liberty. They should be sent, with a separate list of the exhibits, addressed to G. Davison, Camera Club, Charing Cross-road, W.C., and should arrive on or before Monday, December 12. They should be mounted, but not framed. They will be transmitted from, and returned to, London free of charge, and will be sent back as soon as they reach London after the exhibition. We trust a good response will be given to this invitation, and shall await with considerable interest the verdict of the Japanese judges upon what we hope will be a representative collection of all schools of current photographic art.

CONTACT PRINTING.

II.

In a previous article I referred to the necessity of employing only such an amount of light in contact printing aa was best suited to the peculiarities of the negative being printed, and referred to the benefits to be derived by varying the distances that such should occupy from the light, with the interposition of a ground glass-screen, and now proceed to notice other matters of considerable importance in contact printing.

In cases where negatives of dissimilar size to that of the plate being used to print the positive picture upon are being used, it frequently occurs that only a portion of such negatives are required to form the picture, and when such portion permits of its being printed by contact such unquestionably is more easily accomplished in such a manner than would be the case were the negative placed in a copying box and reduced through the camera. In such cases, however, unless proper precautions be taken, there is considerable risk of the negative being damaged by unequal pressure, and also from the edges of the sensitive plate scratching the surface of the negative. Hence, whenever valuable negatives are being used, it is much better to resort to camera printing. With small sizes, however, such as quarter-plate negatives, contact printing may be conducted with a tolerable degree of certainty of immunity from danger.

To guard against scratches and other surface markings to the negatives and sensitive plate, special printing frames have been devised for contact printing, and when such are employed they reduce the chance of danger to the negative considerably. These frames are so constructed as not only to afford a support to the entire surface of the negative, with the view of preventing such being damaged by fracture, often caused by the unequal pressure of the sensitive plate on its unsupported centre or other part, but likewise provide a sort of box or aperture into which the lantern plate is dropped in such a manner as to prevent any slipping or sliding over the surface of the negative; by means of such an arrangement all abrasions of the two surfaces brought in contact are entirely prevented.

These frames are very handy, and should be employed whenever possible. In cases where such are not at hand, however, a very good makeshift can be readily made by any one working on the following plan.

Let it be supposed that the central portion of a whole-plate negative contains some subject of interest that it is desired to print a lantern slide from by contact. Were such to be placed in an ordinary printing frame, and the lantern plate placed over the desired portion, and the back of the frame applied and sprung up, there would undoubtedly be great risk of damage from the pressure being so excessive in the centre of the plate, and, further, a liability of the edges of the plate scratching the surface of the negative when being adjusted to its position in the dark room. These dangers are nearly entirely avoided by employing a stout sheet of glass as a front to the negative in the printing frame. Such will strengthen the negative, whilst the scratching may be avoided by employing a cut-out mask of the same size as the lantern plate. Such is easily acquired by taking a suitably sized stout mounting board, and with the aid of a cover glass and a sharp penknife cut round the edges so as to yield a clear-cut aperture of fully $3\frac{1}{4} \times 3\frac{1}{4}$. This opening is then adjusted in broad daylight, or in good gaslight, exactly over the portion of the negative it is desired to print, and any suitable method employed of holding it firmly fixed in this position until it is removed into the dark room, when the sensitive plate is easily and quickly dropped into the cut-out aperture, the back applied and sprung up, with entire confidence that not only will the exact portion desired be found on the plate, but also an entire freedom from damage to the negative.

The advantage derived from the use of these cut-out masks is very great, and especially will this be felt by those who for the first time experience the comfort of being able in the dark room to place the plate in its exact position, without any of the previous bother and trouble of slipping and sliding such over the face of the negative in the light of a dark room, until it occupies its desired position.

Another great benefit from their employment lies in the protection they afford the edge of the sensitive plate from passing rays of light, and so causing fog round the edges of the picture. Such fogging is a very common trouble with beginners who do not understand the necessity of guarding against such. Some workers, who on the other hand appreciate the benefit of such, do not hesitate to declare the necessity of further guarding against such fogging by even going round the edges of the plate with a solution of Indian ink, so as to prevent entirely all rays of light striking the plate other than those passing direct through the negative. In practice, however, I think it will be found that, provided good thick masks are employed, and

when such fit properly, they will afford sufficient protection without the further precaution of edging the plates.

Within recent years, and especially since the introduction of the justly popular lantern dry plate, there has been a growing disposition on the part of amateurs to strive after the production of red or warm tones in their lantern slides, a result generally acquired by the giving of unduly long exposures, followed by a suitable formula in developments. These long exposures, however, as a rule, tend to a distinct clogging of the high lights of the picture, and further lead to a species of halation; and therefore, whenever such tones are desired, a distinct improvement will be found by subjecting the plate to a backing of any of the well-known preventives against halation.

There is no doubt such backing helps in a wonderful degree to maintain that sparkle so desirous in a good lantern slide. I have known a decided gain to be obtained by using a backing of red sheet rubber firmly applied as a pad in the printing frame. Theoretically, it may be argued that to prevent halation such backing should be applied in optical contact with the back of the sensitive plate; but red sheet rubber, when nice and pliable, takes kindly to a good pressure, and when such is pressed in close contact there is a decided gain in the way of preventing halation. The comfort of using sheet rubber as against the application of a messy compound, that has to be removed previous to development, upon such scrupulously clean plates as are required in this class of work, will be found to be very great, and once used will never be discarded in cases where long exposures are given.

We now come to the consideration of some important matters more intimately associated with the actual exposure or printing of the plate.

In my previous article I referred to what was, all considered, perhaps as good a method as any to employ, viz., gaslight, and when such is contained in a suitable lamp, having a folding-door carrying a good sheet of ruby glass to enable its being utilised as a developing lamp as well, no better means can be found to conduct with ease and comfort a large amount of contact printing.

In dealing with negatives of unequal densities—a fault frequently caused by the uneven coating of the sensitive plate upon which the negative is taken—it frequently becomes necessary to so regulate the light that perhaps one-half of the negative be only exposed a portion of the time necessary to give the other denser parts; and this inequality, as a rule, is found to gradually merge from one side of the plate to the other, or, in other words, there are no hard-and-fast lines of inequality, but just a running gradually from thick to thin sides of the plates.

When such have to be worked upon, there is no better means to employ than the folding-door of the developing lamp for exposure.

When exposing the frame, let the thick portion of the negative be well ascertained, and then let such portion be placed in position so as to get the light first thrown upon it by the opening of the door of the lamp; then, by a judicious waving backwards and forwards of the door, almost any amount of exposure may be given to any portion of the negative, and when such is placed at, say, a distance of twelve or eighteen inches from the door of the lamp, with an intermediate ground-glass screen a few inches in advance between it and the light, the wafting of the door of the lamp backwards and forwards will act just like a blender, and work wonders in the way of yielding harmonious results in cases of great inequality.

At other times it may be necessary to subject a negative to a considerable amount of dodging, such as the application of ground-glass varnish or other non-actinic medium: but, as such treatment does not properly come under the category of contact printing, I need not at this time enter into any details of what is known as *dodging*. It is a very wide subject in itself, and perhaps at some future time I may pen a few remarks for the benefit of the readers of the JOURNAL upon this subject. Meantime, what I have written about contact printing will be found to yield immeasurably superior results to such when conducted by the happy-go-lucky method of holding a negative unsteadily in the hand at ever-varying distances to the flame of an ordinary naked gaslight.

T. N. ARMSTRONG.

PYROGALLIC ACID, OR PYROGALLOL.

GALLIC acid was on hand at the birth of photography, says "W. N." in the *Beacon*, and it, or its derivative, pyrogallic acid, has played an almost continuous part in its development in more senses than one ever since.

I say *almost* continuously, because there was a pretty long break during the reign of the wet collodion negative, when a salt of iron took its place; but the introduction of the dry plate, and especially the gelatino-bromide variety, soon restored it to its former position.

Talbot's discovery of how to produce an invisible but developable negative image was the foundation on which the wonderful and beautiful superstructure was reared, and gallic acid was the agent employed in the development, not discovered by accident, as is generally believed to have been the case with Daguerre and mercurial vapour, but by reasoning from a knowledge of the nature of the work required, and an acquaintance with the properties of the acid.

Gallic acid is found only to a very limited extent in certain vegetable productions, and its main source is the gall-nut, Aleppo galls yielding it to the extent of about fifty per cent. Gall-nuts, however, do not really contain more than three per cent. of gallic acid, and probably, unless under certain conditions, none at all. But they contain generally over forty per cent. of tannin or tannic acid, which, during the process of manufacture, is converted into gallic acid. Powdered galls are mixed with water to the consistency of a thin paste, and exposed to the air for several months, water being added from time to time to make up for loss by evaporation. The mouldy mass so obtained is boiled in a large quantity of water, filtered, and the liquid set aside, when a large quantity of gallic acid will crystallise out. This, after purification by recrystallisation, is the gallic acid of commerce, and is soluble in 100 parts of cold, and three parts of boiling, water.

Gallic acid is indebted for its early application as a developing agent to its power to reduce the salts of silver to the metallic state; the photographic image in the Talbotype as well as the wet-collodion process, being formed of metallic silver thrown down from a solution of the nitrate, and attaching itself only to those portions of the film or paper as had been acted on by light, especially when the action of reduction was suitably controlled by either acetic or citric acid.

One drawback to the employment of gallic acid was its low solubility—only a little over four grains to the ounce—and this gradually led to the employment of its derivative, pyrogallic acid, or more correctly, pyrogallol, which is not only more active, grain for grain, but soluble to the extent of one in two and a quarter, or in a little over twice its weight of water.

When gallic acid is heated to 420° Fahr. it is split up in pyrogallol and carbonic acid thus:

$$C_7H_6O_5 = C_6H_6O_3 + CO_2$$

Gallic acid. Pyrogallol. Carbonic acid.

It is generally produced by heating a dried aqueous extract of galls in a suitable wide-mouthed pot or vessel, covered by a paper cap. When decomposition takes place, the pyrogallol sublimes and is condensed on the inside of the cap in light feathery crystals, the lighter the better, in the olden times, it was supposed to be. On referring to my note-book of those days, I find I paid for pyro at the rate of fifteen shillings ($3.60), and a following entry shows the hypo cost twenty-four cents a pound. My stock dealer then was the chemist included in "The Lights of Other Days," of the last year's volume of the *Beacon*, and, as he made the hypo himself, I doubt whether, at that long price, it paid him as well as at a later period when it was reduced to five cents a pound.

Pyrogallol, like gallic acid, readily reduces salts of silver to the metallic state, and soon almost, if not altogether, displaced the less soluble and less active acid; but only to be displaced, as I have already said, by the salts of iron. With the introduction of dry plates, however, a new method of development became necessary, as the image, instead of being formed by reduction of added silver nitrate, was produced by decomposition of the silver bromide itself. And for this purpose the pyro, although acting in a different way and indirectly, was found to be the right thing in the right place.

As to the exact nature of the latent image doctors still agree to differ, but the balance of evidence is in favour of the sub-bromide theory, which is that light liberates one-half of the bromine of a molecule of the silver bromide, leaving that molecule in a state of readiness to give up the other half to anything for which it has an affinity. Nascent hydrogen, that is, hydrogen at the moment of separation from a body with which it was in combination, fills the bill, and pyro, in consequence of its greed for oxygen, gives the hydrogen a chance.

When a plain solution of pyro is poured over a plate, only a very slight action takes place; partly because pyro only acts vigorously in the presence of an alkali, and partly owing to the fact that the union of an atom of hydrogen with an atom of bromine forms a molecule of hydrobromic acid, which possesses restraining power to stop further action. The addition of an alkali serves the double purpose of vastly increasing the oxidising power of the pyro and, at the same time, uniting with the hydrobromic acid, forming the much less restraining substance, sodium, potassium, or ammonium bromide, as the case may be.

It will thus be seen that the modern dry-plate developer is essentially an oxidiser, that is, a body having a strong affinity for oxygen, strong enough, under favourable conditions, to decompose water; but it must be something more. It must be one the oxidation product of which is either insoluble in water, or, if soluble, have no injurious effect on the haloid salts or the gelatinous body in which they are retained. This to a considerable extent limits the sources from which developing material may be drawn, although recent investigation has given us several new bodies, each possessing some peculiarity that is likely to make it available. Eikonogen, hydroquinone, para-amidophenol are a few of them, and while it is possible that for certain purposes they, or one or other of them, may be better than the good old pyro, they must, in the mean time at least, take a back seat when all-round work is in question. It may be that the average photographer has in pyro the confidence begotten of long acquaintance, but the fact is clear as noonday that, however much he may experiment with those newer candidates, he turns to his old love when he wants to feel certain of being at his best.

WINTER WORK WITH GELATINO-CHLORIDE PAPER.

In the leader on page 722, which treats the question of how to expedite work for Christmas, one expedient, which very likely will prove to be a very useful one, has not been mentioned—namely, the printing process with aristotype paper with development. Since it has been found that perfect prints may be obtained on faintly exposed gelatino or collodio-chloride paper by subsequent development, the printing process with bromide paper has found a rival which cannot be over-estimated, even with regard to the rapid-printing side of the question, an exposure of a few minutes being generally sufficient to produce by development a print on aristotype paper which cannot be distinguished from a printed-out picture. Considering, on the other hand, that the aristotype process offers some great advantages over the printing process with bromide paper as regards simplicity, range of tones, cheapness, &c., it will be evident that this new process will become a very useful one in expediting winter work.

For one special brand of aristotype paper, namely, for that manufactured by the firm of E. Liesegang, of Düsseldorf, a ready-prepared concentrated developing solution has been introduced by the same firm, under the name of "aristogen." It needs only to be diluted with twelve parts of water before use, the subsequent treatment of the prints being equal to that in the well-known printing-out process with aristotype paper. The print, which, as mentioned above, may be a very faint one, is placed in this solution without being washed previously. The image begins to appear in about half a minute, and after about three minutes the development will be completed. It is well to develop it a little deeper than the finished print is desired to be, since in the subsequent fixing bath the intensity of the print will be reduced to some degree. After being well rinsed, the print should be placed in the usual combined toning and fixing bath, and after the desired tone has been obtained it is thoroughly washed in several changes of clean water. Much depends on the perfect cleanliness of the developing dishes, which should be cleaned previously with nitric acid. It is a good plan to make a few trials with prints of small dimensions, which are printed to various degrees in the printing frame. Generally, the tone obtained will be a beautiful rich dark brown.

A singular behaviour of the aristogen developer has been observed by Herr R. E. Liesegang, it giving soft prints from hard negatives, if the developing solution is allowed to act on the print for a sufficient long time. This may be attained either by diluting the concentrated stock solution to a greater extent, say with from thirty to forty parts of water, or by exposing the paper only a very short time, and using the normally diluted developer. It will be seen that this property is opposite to that shown by developers for gelatino-bromide paper, which in the case of short exposure will give a harsh print.

The above-mentioned "aristogen" developer is so far as I know a concentrated hydroquinone developer containing sodium acetate. It keeps well for a long time if kept in well-stoppered bottles.

Many other developers have been recommended for the same purpose. A good one is the following, given by S. Corsi in the *Bulletino della Soc. Fotogr. Italiana*:—

Water	100 c.c.
Sodium sulphite (concentrated solution)	10 „
Acetate of soda (20 per cent. solution)	5 „
Citric acid (20 per cent. solution)	5 „

After the ingredients have completely dissolved, a teaspoonful of pulverised pyrogallic acid should be added. The latter may, however, be replaced by ten c.c. of a ten per cent. aqueous solution of para-amidophenol, or of an alcoholic solution of hydroquinone. After development the print is placed in water slightly acidulated with citric acid, and, after well washing, it is treated in the usual way with the combined toning and fixing bath. It will, however, be necessary to modify the developer to some degree, according to the brand of aristotype paper employed.

According to Herr R. Ed. Liesegang, a faintly exposed print on aristotype paper may be developed in a concentrated aqueous solution of tannin in about twenty minutes. The tone acquired is reddish-brown, similar to that obtained with "aristogen." A slight yellowish-brown muddiness of the liquid will be produced, which, however, does not adhere to the film. The ground of the picture remains purely white. If some silver nitrate be added to the tannin solution, the latter will give prints full of contrasts. SIGMA.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

13. *Definition at the Centre with the Largest Stop, —— C. I. Stop, No. —— gives —— definition over the whole of a —— inch by —— inch plate.*

The system by which the defining power is measured consists in ascertaining what is the thinnest black line of which the image is just visible, the test being conducted in the following manner. The test-object consists of a thin straight strip of steel, about 0·1 inch wide, and about an inch long; it is capable of being rotated about an axis in the direction of its greatest length, thus, if seen against a bright background, making it appear as a black line of varying width; when presented edgewise to the objective, it is so thin that the image becomes invisible; and there is an arc so graduated that the angle subtended by the two edges of the strip at the lens can be at once read off, thus giving a measure of the apparent thickness of the line. The test-object is placed as far as possible from the lens in a darkened room (at Kew the accommodation in this respect leaves much to be desired), and beyond it is a ground-glass screen illuminated by a lamp.

In order to test the defining power of a lens in the centre of its field, the focus is first very carefully adjusted on the ground glass, and the test-object is then slowly revolved from the edgewise position, where its image is invisible, until the first appearance of a dark line can be seen against the bright background; the angular width of the line is read off, and is noted as a measure of the defining power of the lens in the centre of its field. The light of the lamp is regulated so that the image of the line can be seen as soon as possible.

Besides measuring the defining power where the axis of the lens cuts the focal surface, an observation is also made at a point representing the extreme corner of the plate of the size for which the lens is being examined, that is, at a distance from the centre equal to half the diagonal of the plate. As the object of this second test is to measure the general definition over the whole plate, the focus is taken at a position half way between the point of observation and the axis of the lens, this being the method generally adopted by practical photographers when desirous of getting the best general focus. It is necessary, moreover, that the test-object should be so arranged that the steel strip makes an angle of 45° with the horizon; for, since the diffusion of the image near the margin may be due to astigmatism, a false impression of the defining power will be obtained if the image of the dark line coincides in direction with either of the focal lines; whereas, if it bisects, the angle between them, as will then be the case, there is no error in the result from this cause. The test is not, however, conducted in quite the same way as in the first instance; the test-object is set at a known angle, and the stops are slipped in one after another, beginning with the largest and going on to smaller ones, until the image of the black line on the bright ground is first just visible; the C. I. No. of the stop with which the lens gives definition up to a known standard at the extreme corner of the plate is thus ascertained, and, as it may fairly be assumed that the definition will be no worse than this at any other part of the plate, it follows that the defining power over the whole plate comes up to or exceeds the standard selected.

It cannot be denied that the defining power is the most important quality of a photographic lens for almost every purpose, and yet the best method of testing definition has never been satisfactorily discussed or considered. If a thoroughly good test could be devised, it would be hardly necessary to examine at Kew for curvature of field or for astigmatism, for these defects are only hurtful in so far as they affect definition. But it must be confessed that the method above described is open to some

* Continued from page 761.

objections, and the following discussion is merely intended to show that it is the best that could at present be devised.

In considering this question, it was natural that attention should first be turned to the excellent arrangements adopted at Kew for testing the definition of telescopes. The method generally used, especially when dealing with instruments supplied for the public service, is to compare each one separately with a standard telescope by an observation on a distant object; telescopes sent for examination can by this means be *passed* or *rejected*, but hardly classified. But in examining photographic lenses, where there is a much greater variety of form and pattern, it would be quite out of the question to keep a sufficient number of standard lenses to be of any practical use. Thus little assistance was obtained from the experiences gained in the examination of telescopes.

It was necessary therefore to seek some method which did not depend on comparisons with standards, and, in devising such a test, the object most to be kept in view was evidently to diminish as far as possible the errors due to the variations either in the transparency of the atmosphere or in the personal qualities of the observer.

With regard to the first point, that is, the effect of fog, mist, and dust in the air, the only way to avoid errors from these causes appeared to be to conduct this test in a room. This was considered especially necessary in a climate like that of London. It is no doubt theoretically right to examine portrait lenses, or lenses for copying plans, by observations on a test-object not too far away; but for landscape lenses a distant test-object would, from other points of view, be preferable, and the adoption of the examination in a room was only the choice of the lesser of two evils.

With regard to variations due to the personality of the observer, the case is more difficult. Probably the most important consideration is that the test should not be based on a mere judgment, the reason for which one person cannot readily communicate to another. In many works on photography the extent of field over which the lens produces a "sharp" image is discussed, as if by mere inspection this could be determined, whereas no two people would exactly agree as to where the diffusion of the image was sufficient to be classed as want of sharpness, and no two objects would serve equally well for such a test. It is essential, at such an establishment as the Kew Observatory, that the observer should obtain some definite numerical result from his examination, even though it may be considered advisable to merely employ general expressions in the wording of the certificate; under any other system it would be impossible for any length of time to prevent the standards from varying.

Still more difficult is it to avoid errors from actual variations in eyesight, whether between different individuals or at different times in the same individual. Some general conditions may, however, be laid down. When the illumination of an object is very feeble, the subjective light of the eye, as it has been called by Helmholtz, plays an important part in determining the least intensity of illumination which is visible, and this subjective light is a very variable quantity; the eye increases in sensitiveness for a long time when light is excluded from it, the increase at first being very rapid, which may be another way of expressing the same fact. Hence, any feebly illuminated object must be a bad test-object, for its appearance will vary very materially according to the state of the eye. On the other hand, if the illumination is too bright, the eye will be much influenced by irradiation, and the subjective effect on the eye will be a bad indication of the true condition of the object; moreover, as irradiation is the effect on the appearance of an object produced by brighter surrounding objects, and, as this effect diminishes as the differences of shade get less, the test-object should show no marked contrasts in illumination. But, in applying these general remarks to the case under consideration, it must be remembered that it is not the test-object which is seen by the eye; it is the image of the test-object as produced by the lens under examination. Hence, it appears that the test-object should produce an image of medium intensity of illumination, and one in which there are no great differences in shade. The test-object used at Kew, it will be remembered, consists of a perfectly black object seen against a bright background, and it might therefore appear as if it were not a good selection. In order to prove that, as a rule, the differences of shade in the image are small, and that no objections can be raised to the Kew test on theoretical grounds, it is necessary to show what is the effect on the image produced by a want of defining power in the lens.

The result of bad definition in the lens is to make the image of a point occupy a sensible area on the photographic plate, and consequently to prevent the image of the edge of a surface from being sharply indicated. The general effect can be best illustrated by means of figs. 7 and 8, where the abscissæ are enlarged dimensions measured on the plate, and the ordinates indicate the intensity of illumination at each point. In fig. 7 let a, c, b represent a section through the image of a small spot of light. In fig. 8 let the curve f, h, k represent the actual image of the edge of a bright surface, which would be represented by f, d, c', k if the defining power of the lens were perfect; it is evident that $a'b'$ in fig. 8 is equal to the limiting value of $a\,b$ in fig. 7, as the spot of light becomes infinitely small. In fig. 10 is shown the effect of bringing two bright surfaces near together; that is to say, of a dark line as seen against a

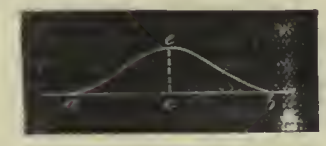

Fig. 7.

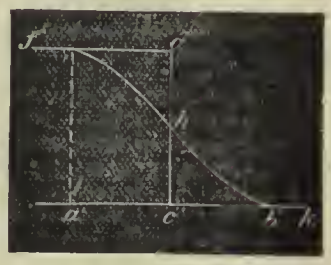

Fig. .

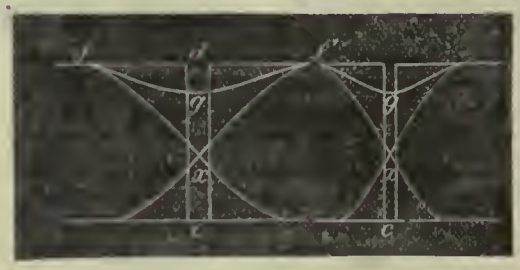
Fig. 9.



Figs. 10 and 11.

bright background; f, g, f' will represent a section through the image of the line, $g\,x$ being equal to $x\,c$. If this curve is turned upside down, as in fig. 9, it can be shown that it represents the image of a bright line on a dark ground.

In this latter case—that of the bright line on the dark ground—it can be readily seen that the effect of narrowing the slit of light will be to decrease the illumination $g\,d$ at the centre of the line until it becomes zero as the slit closes. The worse the definition of the lens, the sooner will the centre of the line reach the limit of visibility; but, by ascertaining what is the width of the finest bright line just visible, a good test for defining power will not be obtained for the following reasons: in the first place, the illumination of the image will be feeble, which has already been shown to be objectionable; and in the second place, since with feeble illuminations the ocular sensation varies as a first approximation as the intensity of the illumination, considerable errors would arise through the difficulty of obtaining a constant illumination through lenses of different types.

These objections do not apply, however, to testing definition by finding the width of the finest dark line that can be seen against a bright background. In this case, as the line becomes thinner, the illumination at its centre increases, until it reaches that intensity of illumination which can no longer be distinguished by the eye from the illumination of the field. If the illumination $c\,g$ in fig. 10 can be distinguished from $c\,d$ by the eye, it is evident that a blurred image of the dark line is visible, and, if any illumination greater than $c\,g$ is indistinguishable from $c\,d$ by the eye, it is evident that the figure represents the image of the thinnest black line which is visible. Fig. 11 represents generally the same condition of things as that shown in fig. 10, except that the defining power

of lens is much better; and it will be seen how much finer the line must be in this case to produce the same proportional illumination at its centre; that is to say, before the limit of visibility is used. Now, there is a certain intensity of illumination at which and about which the eye is at its maximum of sensitiveness to differences of shade, and this is when the object is what would be described as not bright and not dark; between these wide limits the minimum difference of shade visible is a fixed proportional part of the total illumination. This proportion differs with different observers, but not to a very great extent. Hence, if a plan is adopted by which a dark line on a bright ground can be made to vary in thickness, and if the illumination is arranged so that the eye is at its maximum sensitiveness (that is therefore so that the line remains longest visible as it diminishes in width), then the moment at which it disappears will occur when the difference of intensity of illumination of the centre of the line and the field is the minimum difference of shade discernible by the eye, and this will be independent of the actual intensity of the field, and will not vary much with different observers. But it has been shown that the thickness of the line does vary with the defining power of the lens, and it may therefore be concluded that the test adopted at Kew is not open to serious objections on theoretical grounds.

In the foregoing discussion it has, however, been assumed that the curve representing the image of the edge of a surface is such as that which Helmholtz has shown to be produced as an ocular effect by the circles of diffusion being due to want of accommodation of the eye itself;* it will be observed that no part of the curve is tangential to the vertical. If, however, the curve is similar to that given by the same

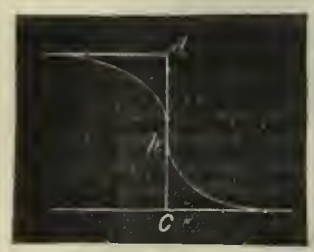


Fig. 12.

Fig. 13.

author as being due to dispersion in the eye, and illustrated in fig. 12, it will be seen that the result of gradually diminishing the thickness of a line will not be exactly as above described; for, however thin the dark line on the bright ground becomes, the intensity of illumination at its centre can never be more than twice *ch*; and, if the ratio of twice *ch* to *cd* is, less than a given ratio, the image of the black line will remain visible until it is so thin that the eye cannot perceive it. Therefore it might come about that two lenses giving images of the edges of surfaces as different as *flhf'* and *nlhn'*, as shown in fig. 13, might give equally good results under the Kew test for definition, because in both cases the limit of visibility would be due to the minimum size of the line visible by the eye, and would have nothing to do with the definition of the lens. Helmholtz remarks on the very little evil effect of a diffusion represented by the curve shown in fig. 12, since the true edge is always visible. Hence we may assume that the Kew method still gives in such cases a good practical test for definition, though it does not test the amount of dispersed light over the image of fine lines, or, as the photographer would say, the brilliancy of small objects. In fact, since the definition of an objective could only be rigorously expressed by a curve (or, more accurately, a surface) with dimensions, it is impossible for any one result to give all the information on this head which might be desirable.

As the eye is capable of detecting a difference of shade of about one per cent. of a moderately illuminated field, it will be only necessary for the curve shown in fig. 12 to be tangential to the vertical for one per cent. of its height to render the image of an infinitely thin line visible in so far as that visibility depends upon difference of shade. But take the case of a line not absolutely black, and seen against a bright background; then, in fig. 10, the illumination of the centre of the image will be represented by *gc*, *plus* some proportional part of *gd*; in comparison with the case of the absolutely black line, it can be shown that the curve must be tangential to the vertical for a proportionately greater distance before the shade of the centre of the image of the infinitely thin dark line will be sufficiently deep to form a visible contrast. For instance, if the line is illuminated to nine-tenths of the intensity of illumination of the field, the curve must be tangential to one-tenth of *dc* (see fig. 10) before this condition of things occurs. A test depending on the thickness of a line which is darkened to a definite proportional intensity of the field would therefore present this disadvantage, that there would be fewer occasions on which different degrees of imperfection of definition of lenses would show the same result in testing; such a test may therefore in future be adopted at Kew.

It should, however, be remarked that in the whole of the above reasoning it has been assumed that the minimum proportional difference of shade visible is the same in a thin line as in a thick one, which can hardly be the case. But this false assumption will not, it is thought, vitiate the general conclusions arrived at.

It is, of course, conceivable that the actinic rays will be brought to either a better or to a worse focus than the visible rays; it is believed, however, that no serious error is likely to result from the test being done by the eye, and not by photographic methods; it is almost certain that the curve representing the edge of a surface will have the same general character in the two cases, and, therefore, that the results obtained with the eye will be a good indication of those which would be obtained by photography.

Leonard Darwin, Major R.E.

CRESCO-FYLMA.

Messrs. Hill Brothers, of Surbiton, last week gave a demonstration of this method of enlarging negatives and transparencies before the London and Provincial Photographic Association, and since then they have afforded us an opportunity of testing the properties of the solution.

The process is simplicity itself. The negative or transparency (preferably not one developed by the aid of pyro and ammonia, or a fixed alkali) is immersed in a solution consisting of three parts of the cresco-fylma to one of water. After a few minutes the film frills, and becomes detached from the support, and is, after another minute or two, transferred with its own support to a dish of plain water, in which is placed a plate the approximate size of the degree of enlargement sought. The original glass plate is then withdrawn, the film carefully guided on to the new support, and smoothed out upon it. The expansion proceeds in the plain water, attaining its maximum in the course of a quarter of an hour or so, when the enlarged picture is removed from the solution and dried on a level surface.

Following the instructions, we successfully enlarged some ¼-plate amidol-developed negatives to about half-plate size, the solution stripping the films with engaging facility and evenness. The temperature of the solution was between 60° and 70° Fahr., and the maximum enlargement to about 6¼ × 4¼ was complete in less than a quarter of an hour.

The enlarged pictures, when dry, require washing. The loss of density with this degree of enlargement is inappreciable, and, after drying, intensification may be resorted to. We note that the solution, diluted in the proportion 1 : 4, may be used for stripping purposes pure and simple.

The uses to which cresco-fylma may be put are so varied that there are few amateurs, and probably not many professionals, who could not turn it to profitable account. It is, in brief, a capital plan of enlarging without the necessity of using an optical system. Enlarged negatives and positives, stripping, transfers of enlarged pictures to various supports for ornamental purposes, enlarged opal pictures, reversing negatives for carbon and process work, are among its obvious uses.

The process is a simple and apparently reliable one, and on these grounds deserves to be known. A six-ounce bottle of the solution will, it is said, enlarge twenty-four half-plates into as many whole-plates. Hence the process is commendably inexpensive.

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The fourth annual Exhibition of this Society was held at the Peckham Public Hall on November 24, 25, and 26. About 600 photographs were on view, rather less than forty of the number being not for competition. In those same few pictures, however, resided perhaps the chief artistic and technical excellence of the Exhibition, since they included Mr. S. N. Bhedwar's "Naver" series and some fine examples of the President's (Mr. F. W. Edwards) treatment of Tinworth panels and architectural subjects. The Exhibition, it will be seen, was a tolerably large one numerically, and doubtless on that ground gave pleasure to its supporters and visitors; but, regarded from the standpoint of art photography, or even of mere technique, the exclusion of a considerable percentage of the photographs hung would have been a wise step.

The Judges were Messrs. F. P. Cembrano, jun., A. Horsley Hinton, and Andrew Pringle, and their awards were as follows:—

Class A, silver medal for the best general exhibit, Mr. C. H. Oakden. Class B, silver medal for the best picture exhibited, irrespective of size,

Mr. Thomas H. Powell. Class C, silver medal for the best set of six lantern slides, Mr. W. Rice; bronze medal for the second best set of six lantern slides, Mr. H. Esler. Class D, silver medal for the best series of six views taken within a radius of five miles from Hanover Hall, south of the Thames, withheld. Class E, silver medal, portraiture, best set of six, withheld. Class F, bronze medal for the best picture taken on any of the Society's excursions, irrespective of size, Mr. William Howell. Classes open for the members of the South Metropolitan Photographic Societies: Class G, silver medal for the best picture shown, irrespective of size, Mr. C. H. Oakden; bronze medal for second best ditto, Mr. H. Kirby. Class H, silver medal for best set of six lantern slides, Mr. F. Goldby (of Brixton and Clapham Camera Club); bronze medal for the second best ditto, Mr. C. H. Oakden.

Mr. Oakden's general exhibit comprised, if we mistake not, several of the excellent interiors upon which we favourably commented when they were at the Leytonstone Exhibition. His view of *Across the Octagon, Ely Cathedral*, was one of his general exhibits, and also enabled him to take a silver medal in the classes open to South Metropolitan societies. Mr. T. H. Powell's medal for the best picture exhibited was taken for the *Rising Chemist*, a small study of a child playing with a pestle and mortar. Mr. W. Howell's bronze medal for *The South Entrance, Canterbury Cathedral*, was honestly earned. This exhibitor's other work, including some well-chosen views of Arundel, carefully printed and judiciously framed, was very good. Mr. T. C. Kirby showed numerous portrait studies, for one of which he took a bronze medal. It will be observed that two medals were withheld, for what reason we did not gather. The Judges' reasons should, we think, always be made public.

Of the remaining exhibits, Mr. H. E. Farmer's were conspicuous by merit, some of his cathedral interiors being so good as, in our opinion, to have deserved an award. Mr. W. Rice's barge pictures on the Thames off Paul's Wharf were capitally treated studies, being clearly defined and well exposed, and in a frame of landscapes (some of which, by the way, were seascapes) the same gentleman showed other successful examples of pure photography, that is, photography minus impressionism. Mr. J. F. Kelly had some ably rendered Scotch views, and Mr. H. Sandland a fine study of a tiger at the Zoo.

The apparatus section appeared to be popular with visitors, especially the exhibits of the Platinotype Company, Mr. W. F. Slater (who had an appropriate display of various descriptions of picture frames on view), Messrs. D. Noakes & Son (a capital little exhibit of lanterns, accessories, &c.), Messrs. Adams, Hy. Crouch (Limited), Dollond & Co., Gill & Son, J. R. Gotz, Howell & Son, Percy Lund & Co., Moody & Gattens, Mr. H. Park, Messrs. George Philip & Sons, Mr. T. H. Powell, Messrs. W. B. Whittingham & Co., Messrs. A. R. Wormald & Co., &c.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY'S EXHIBITION.

It is a pity that so excellent a display of photographs as that collected at the Fourth Annual Exhibition of this Society on Monday last could only be on view for one evening, as it was certainly deserving of the inspection of a larger number of visitors than could possibly have gained access to them in the short space of three hours. This is equally a loss to the general public and to the Society. On former occasions we have expressed satisfaction at the hanging and other details of this annual Exhibition, and, after recent unfavourable experiences elsewhere, it is again our pleasure to note not merely the neatness and good order of the *ensemble*, but also the high general average of the work shown. The Judges were, as usual, Col. Gale and Mr. R. W. Robinson, and, although they did not award the full number of certificates placed at their disposal, we understand that the reason assigned was the difficulty of knowing where to withhold them after a certain point.

Mr. C. O. Gregory in *There's a Storm Brewing*, showed a crisp wave study which might have been improved by the absence of the figure. Regret must follow Mr. McIntosh in his retirement from photography, as in *A Gleam of Light the Gloaming follows fast*, a really poetical study of a sunset behind a bank of trees with water in the foreground, despite possibly too much heaviness in the shadows, a result was achieved which indicated the highest promises. Of Mr. Marchant's exhibits we preferred a soft delicate platinum study of *Burnham Beeches*, and *A Woodland Road* having a pleasing warm tone. Mr. Mummery took a certificate for *Low Tide on an Essex River*, a bromide study of the seashore with figures, and in his study of a lonely figure in *Across the Plough Land* he unmistakably betrayed Emersonian influence. The various attitudes of the little dog in *A Professional Beauty*, by Mr. R. H. Wynne, were cleverly portrayed; and Mr. J. C. Plunkett showed a bright but soft view of *Old Shanklin*. Mr. Marchant's *Still Waters* (the water being very naturally rendered,) *Shipping at Cowes* (crisply defined), and *Lilies* (a charming flower study), bore testimony to the President's versatility; and as a relief to the now fashionable fuzziness, Mr. C. O. Gregory's *Spring Views* in Epping Forest and Regent's Park were distinctly refreshing in their excellence of definition, exposure, and printing. The technique of these little pictures was admirable.

Mr. S. T. Chang's pictures showed a commendable advance, while Mr. F. Cherry's *Reredos, St. Albans*, was perhaps the best interior shown. We liked the pose and general treatment of Mr. C. Beadle's head study *Elsie* (a very young lady), albeit the shadows were rather sombre; and of Dr. Mason's Devonshire coast views, perhaps *Lynmouth Harbour*, breezy and animated pictorially and good photographically, was the best. Mr. A. J. Golding was awarded a certificate for *Towards Evening on the Yare*, the composition of which was materially assisted by the smoke of a steamer; there was, however, possibly too much foreground in the shape of water. Mr. Golding's other exhibits (especially *Outward Bound*), though striking us as familiar, were exceedingly good, and he is an acquisition to the Society.

Mr. T. C. Lathbridge showed good architectural subjects at Arundel, and Mr. W. Taylor took an award for a crisp and delicate study, *The Lynher*, in which the relative values of the gradations were well expressed. A *Copy of an Engraving*, by T. C. Lathbridge, was a perfect example of this class of work. Mr. Walker's *Lake Views* deserved notice by their excellence of exposure and clearness. Mr. Staveley's *Trees at Chingford; The Nave at Bath Abbey* by Mr. W. Taylor; Mr. F. Gandon's enlarged picture of *Mr. J. McIntosh;* Mr. Lathbridge's *Sussex Cottages;* Mr. A. J. Johnson's clever, unaffected study of *At a Truant School* (the latter a capital rendering of the small figures) merited notice. In *A Much Prized Picture*, a woman and boy at a rural doorway looking at a picture, while an old fellow is sitting by enjoying a quiet pipe with a smile, Mr. H. Walker showed a delightful view not unworthy of Colonel Gale. It was a really admirable picture from all points. Mr. S. E. Wall also took an award for *Going an Errand*—a boy and girl gossiping by the way; and Mr. Golding one for his series of lantern slides. Mr. Wall's exhibits, particularly *Loitering Home from School* and *When Shadows Lengthen, Little Stanmore*, were remarkably good.

We congratulate the Society on its charming little Exhibition; but we can only with difficulty forgive them the introduction into the catalogue of the word "rehalogenisation" as applied, we suppose, to reduction of negatives by the bleaching method.

TUNBRIDGE WELLS AMATEUR PHOTOGRAPHIC ASSOCIATION EXHIBITION.

The sixth annual Exhibition of this Association was held on November 23, 24, and 25. There were twenty-eight exhibits in architecture, fifteen interiors, seventy-seven landscapes and seascapes, ten *genre*, and a large number of lantern slides in the classes confined to members. The total number of competitive exhibits amounted to 768. In the unavoidable absence of Sir D. L. Salomons, the Exhibition was opened by the Rev. A. T. Scott. The Judges were Colonel J. Gale, Mr. G. Davison, and Mr. William Mayland. Besides the exhibits for competition there were in addition some fine photographs sent by Mr. H. P. Robinson. Among others, Colonel T. Dawes exhibited a number of interesting pictures, which were said to have been taken during the last occupation of Kandahar by the British, in 1880 and 1881, by Sir Benjamin Simpson. An interesting exhibit was a triple lantern and stand, belonging to Sir D. L. Salomons.

In Class I., architecture exterior or interior, Mr. E. R. Ashton, who sent a collection of Algerian views, gained mention for *Entrance to Great Mosque*, in each case the native figures being most artistically grouped.

In Class II., interiors, some interesting views of the drawing-room at Broomhill and Sir David Salomon's workshop came from Mr. J. D. Morgan.

In Class III., landscape and seascape, Mr. G. Lewis secured honorable mention. The Rev. A. T. Scott sent a frame of half-plate pictures, in which the effects were very picturesque. Mr. J. Chamberlain, the Secretary, sent two pictures taken by a pinhole instead of a lens.

In no less than thirteen classes (in some of which there were numerous entries) the Judges withheld the medals on the self-provided "ground of insufficient merit." A Judge's duty is to judge, and, if these three gentlemen were incapable of making the awards in the various classes in accordance with what they conceived to be the relative merits of the pictures shown, they had no right to undertake the office. Under what canon of judicial privilege do they claim to fix their own standard of excellence, high or low, at their own sweet will? The wholesale

manner in which these medals were withheld at Tunbridge Wells constitutes a piece of arrogance to which we hope neither this nor any other Society will in future submit. We hope to hear more of this matter.

In the Open Classes Mr. B. Alfieri took a silver medal with the *Grey Dawn*, which was recently shown at the Camera Club, and Mr. A. Horsley Hinton was similarly honoured for his *Fenland*, he also showing *Winter's Requiem* and *Lowland Solitudes*, the latter of which was on view at Hackney, and, to our thinking, deserved recognition there. Mr. A. R. Dresser had a selection of works, including the Pall Mall *Aylesford*, and Mr. J. E. Austin showed *Worn Out*, a picture that was also distinguished there. Mrs. S. Francis Clarke repeated her Leytonstone success with *Aha!* A bronze medal was awarded to Mr. A. G. Tagliaferro for *All's Fair in Love and War*, and silver medals to Messrs. E. G. Lee and T. M. Brownrigg for lantern slides. We congratulate the latter veteran worker, who has been none too fortunate of late with his exhibits. Mr. Ralph Robinson was represented by *A Mussel-gatherer*, *Young Vagabonds*, and *A New Pet* (silver medal), the very clever and suggestive picture which we singled out for commendation at the Camera Club Exhibition. Mr. Bhedwar's series secured honourable mention, and in displays of portraiture prominent exhibitors were Mr. H. Yeo, Mr. W. J. Byrne, and Mr. Bhedwar, Mr. Ralph Robinson being the recipient of another silver medal for a really fine portrait of Sir F. Leighton, a similar award going to Mr. F. Seyton Scott for his delightful view in *Kew Gardens*. In the Professional Class Mr. Robinson was also mentioned for his *Washing Day—Normandy*.

In addition to several examples of Mr. H. P. Robinson's work, the non-competitive section comprised pictures by Mr. H. Sandland and others, as well as a large collection of apparatus. Messrs. Elliott & Son showed a capital carbon enlargement of a dog and the Wave picture. It will be seen, from the above brief notice of the principal features, that the Tunbridge Wells Exhibition had all the elements of success, no small credit for this being due to the Honorary Secretary, Mr. Joseph Chamberlain.

EXETER PHOTOGRAPHIC SOCIETY EXHIBITION.

The first annual open Exhibition in connexion with the Exeter Photographic Society was held last week, being opened by Lord Poltimore, himself greatly interested in photographic art and an experienced amateur.

In Class I. the silver medal was awarded to Mr. Edgar Dudley for a series of interiors of Haddon Hall, &c. Mr. A. Norman secured the bronze for a landscape, one of the three shown by him, *A Somersetshire Peep*.

In Class II. the Rev. J. Sparshatt, the Hon. Secretary of the Society, was the recipient of the silver medal for a domestic study, *Family Cares*, the bronze going to Colonel Hutchinson for three Moorish figure studies in platinotype. The honourable-mention card was also appended to a pretty little picture by the Rev. J. Sparshatt.

In Class III., enlargements, the exhibits were not deemed of sufficient merit for the highest prize. Miss Truscott, however, was successful in getting the bronze award for a bromide enlargement, entitled *On the Exe*.

Classes V. to VIII. were open. In the first Class the Judge gave the silver medal to a series of three land and seascape studies in platinotype by Mr. A. Horsley Hinton. Mr. Court Cole was awarded the bronze for three Oxford interiors, and Mr. Hemmons was honourably mentioned for a couple of pretty exhibits.

In Class VI. the Judge was best pleased with No. 249, *Chaff*, a seabeach study of fisher life by Mr. J. E. Austin, who also showed *The Love Letter*, which was also much admired. The bronze medal went to *How's That?* by Mr. R. H. Lord. Mr. J. E. Austin received honourable mention for his *Worn Out*, and Mr. C. B. Moore's picture, *A Veteran's Tale* (No. 267), was similarly honoured.

In Class VII., enlargements, the silver medal was withheld, but a bronze was awarded to Mr. A. Drysdale's *On the Coquet*, one of two sent in, and *Punchinello*, contributed by the Woodburytype Company.

For lantern slides, Class IV., No. 406, Mr. C. Cole, and No. 413, Mr. J. W. Huggins, were placed equal for the bronze medal.

In Class VIII. Mr. J. E. Austin carried off the silver medal, the bronze going to Mr. E. G. Lee, while Mr. A. Pringle and Mr. Taverner were honourably mentioned, the former for Spanish architecture and the latter for flowers.

The Judge, Mr. W. D. Welford, while being unable to compliment the members upon having displayed any great advance upon the work of last year, yet spoke encouragingly, and urged the members to give increased study to pictorial effect rather to mere reproductions of objects in front of the camera. Effort in this direction was, he said, apparent in the present Exhibition, and the great majority of the frames contained work of fairly good technical merit, but lacking in artistic merit.

AWARDS AT THE EDINBURGH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

At the close of the stipulated period for the expression of judgment by the members (November 22) of the best pictures exhibited by members, the Council opened the closed box in which these billets were deposited, and on examination found that the majorities had expressed their opinions to be as follows, carrying the awards stated:—

Class II. Best picture taken during the 1892 Saturday rambles.—Bronze medal, Mr. John C. Whyte.

Class III. Best figure study taken since November, 1891.—Bronze medal, Mr. Jas. C. H. Balmain.

Class IV. Best landscape taken since November, 1891.—Silver medal, Mr. Jas. Patrick; Bronze medal, second best, Mr. W. Lamond Howie.

In the lantern slides competition, the Committee awarded the first prize to Mr. Charles Reid (silver medal), and the second to Mr. James Patrick (bronze medal).

The Exhibition has been fairly well attended, and expression has been given to the wish that it should be kept open a little longer, it not having been probably sufficiently advertised; but, there being no admission money, that would have been expensive.

Our Editorial Table.

W. & D. Downey's Art Studies.

Published by Marion & Co.

At a price so low as to be entirely within the means of every one who loves to be the possessor of a collection of fine photographs, Messrs. Marion are issuing a series of admirable "art studies" from the studio of Messrs. Downey. They are from the life, and depict such feelings and emotions as *Resignation* or *Meditation*, or such character subjects as *The Flower Girl*, *Cecilia*, *Aspatia*, &c. The posing and lighting are just what one would expect from artists of the Messrs. Downey's standing—soft and well defined, without the semblance of want of detail in any part. Things of beauty, they will, being printed in collotype, prove "joys for ever." We urge upon photographers the propriety of possessing pictures of this high class as studies. The ink selected is a warm engraving black, suggestive of platinotype. That there will be a great demand for such charming photographs goes without saying. We have not been informed how many the series consists or will consist of, but this can be learned from the publishers, who are to be congratulated upon putting really admirable artistic pictures within the reach of all, even of the poorest of photographers.

Todd-Forret Magnesium Lamp Specimens.

Mr. A. H. Baird, Lothian-street, Edinburgh, who is the maker of the Todd-Forret lamp, of which we spoke in terms of commendation early in the year, sends a parcel of Meisenbach specimen prints from negatives obtained by its agency, and which show its capabilities. A feature in the lamp is the possibility of giving both instantaneous and time exposures. We are glad to learn that it has a steady and increasing sale.

Christmas Annuals.

Detroit Free Press.—This contains two illustrated stories, one of which, "The Heralds of Fame," by Luke Sharp, is probably the best that this versatile author has ever written. It gives the adventures of a sparkling young American lady and two poets when crossing the Atlantic to New York. The other is "The Tale of the Raven Inn," a haunt of highwaymen in Epping Forest in former times. Both are finely illustrated.

Figaro Illustré.—The illustrations and whole-get up is French throughout, and are printed in bright colours. The text is in the English language, although another edition is in French. It is issued in Boussod, Valadon, & Co.'s best style.

Yuletide—Cassell's Christmas number—contains several comic political and other cartoons, and a good deal of funny reading under the title of "The New Babylon; or, the Dream, the Demolition, and the Democracy."

Convention Stereoscopic Slides.

By A. Seaman, Chesterfield.

Among those who brought stereoscopic cameras with them to the Edinburgh meeting of the Photographic Convention was Mr. Seaman, who is well known as a photographer of ripe experience. He has sent us some of the results of his work on that occasion, embracing mainly groups taken during the ontings of the Convention, and which vividly recall pleasant times and scenes in congenial company at Melrose, St. Andrews, and Callander. They are alike valuable technically and from their associations.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
December 5	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 5	Fillebrook Athenæum	Fillebrook Lecture Hall.
,, 5	Halifax Camera Club	
,, 5	Peterborough	Museum, Minster Precincts.
,, 5	Richmond	Greyhound Hotel, Richmond.
,, 5	South London	Hanover Hall, Hanover-park, S.E.
,, 5	Stereoscopic Club	Brooklands Hotel, Brooklands.
,, 6	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 6	Exeter	College Hall, South-street, Exeter.
,, 6	Glossop Dale	Rooms, Howard-chambers, Glossop.
,, 6	Herefordshire	Mansion House, Hereford.
,, 6	Keighley and District	Mechanics' Institute, North-street.
,, 6	Lewes	Fitzroy Library, High-st., Lewes.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 21.—Mr. W. H. Harrison in the chair.

Messrs. W. C. Hay, W. F. Jones, and J. A. Butler were elected members.

Repairing Celluloid Trays.

Mr. A. Haddon said that it might be interesting to those possessing celluloid trays to know how to repair them if they got broken. All that was necessary to do was to moisten the crack with a little acetone, then press on it a piece of celluloid while still damp. It would be better perhaps to use a solution of celluloid in acetone. Celluloid itself softened at the temperature of boiling water, and might be bent. Mr. Haddon exhibited joined and bent pieces of celluloid in illustration of his statements.

The Chairman observed that acetone was to be obtained commercially absolutely pure at a cheap rate—three to five shillings per pound.

Mr. J. S. Teape used hot water to restore mis-shapen celluloid dishes to their proper shapes.

Reversals.

A short discussion took place as to who was the first to discover that a negative from a negative could be obtained by means of the phenomenon of reversal.

Mr. T. Bolas observed that it was not altogether an unknown thing in the collodion days to secure a positive in the camera with pyro development.

Mr. F. A. Bridge said Mr. Bolas himself was the first to publish the method with gelatine plates.

Mr. Bolas believed that Mr. Foxlee had obtained positives in the camera many years ago.

Cresco-Fylma.

Messrs. Hill Brothers gave a practical demonstration of the working properties of Cresco-fylma, in illustration of which a print, another print taken from an enlarged negative made from the original negative, and a transparency from the enlarged negative were shown. Mr. Frank Hill, in taking a 5 × 4 transparency to effect the enlargement, said the process was as follows: After the plate has been some minutes in the aqueous solution of cresco-fylma, the film would frill and leave its support. The amount of enlargement depended upon the temperature of the water, the effect of using warm water being that the enlargement greatly increased. The film having become detached from the glass, Mr. Hill transferred it to a dish of water containing a sheet of glass, upon which it was then stretched out, the enlargement being to 7 × 5½. The water in which a film had been stripped could be used for stripping a negative from the glass support which might have got broken. In reference to the suggestion that there was loss of detail on account of the enlargement, Mr. Hill pointed out that in the case of the print from an enlarged negative (which he showed) as against a print from the original negative (which he also showed) there was a distinct gain in the enlargement, some lettering on a book not being visible in the original, but seen in the enlargement. In reply to Mr. Mackie, Mr. Hill said the film could be reduced to its original size, but it would lose its adhesiveness. Pyro-developed negatives were not suitable for enlargement, but would strip all right. Answering Mr. Teape, Mr. Hill stated that, in the case of a yellow negative, cresco-fylma acted as a clearing solution. Dense pyro-ammonia developed negatives were the least applicable for the process of enlargement.

Mr. Bolas described Plener's method of stripping and enlarging with hydrofluoric acid. That acid, he said, had an irritating effect on the hands. A mixture of fluoride of sodium and sulphuric acid, for the same purpose, might be kept in a glass bottle.

Mr. W. E. Debenham said that in lantern plates one often had more than one wanted; by this method of stripping and enlargement one might be able to select only just so much as one wanted.

Mr. Haddon asked what was the effect of the solution on the fingers.

Mr. Hill replied that there was not sufficient hydrofluoric acid to injure the fingers. In reply to another question, he said that a six-ounce bottle of the solution would enlarge twenty-four half-plate negatives to whole-plate size. The enlarging action did not depend in any way upon the hydrofluoric acid in the solution, but upon the other ingredients. Films which were enlarged by hydrofluoric acid alone were very rotten.

Messrs. Hill were thanked for the demonstration of what the Chairman described as a "very interesting process," and, after some further discussion, the meeting terminated.

Hackney Photographic Society.—November 22.—Mr. Hudson presented the Society with a new arrangement for using gas from any tap with the lantern. Mr. Ponlson showed some new kind of ordinary silver paper, which was glossy without having been burnished. It was not on the market at present. A demonstration was then given by the Autotype Company's representative. The lecturer proceeded to say that in 1839 it was discovered that paper with bichromate potash darkened by exposnre to light, which discovery subsequently led to finding that sized paper darkened more rapidly, and that the darkened gelatine is insoluble. Mr. Swan patented a process with pigmented gelatine. The lecturer then gave a description of single and double process of transfer. The advantages, he said, were permanency and variety of colours. Ready-sensitised paper would keep from a fortnight to a month if kept dry. To save the trouble of double transfer a mirror at an angle of forty-five degrees was used. Several exposure meters were handed round, enabling people to see how the exposure was determined upon. Demonstration was then given showing the action, single and double transfer being shown. Various questions were asked incidentally by Messrs. Avent, Gosling, Barker, Beckett, and others, and the lecture was one full of interest. The ease of manipulating the paper was surprising.

Aldenham Institute Camera Club.—November 22.—Mr. W. Vere Mignard gave *A Chat on Light*. Having shown how difficult it is to properly define light, the lecturer showed the fallacies of Newton's "emission" theory, and then briefly pointed out the essentials of Huyghen's "undulatory" theory. He showed the impossibility of light travelling in any but straight lines, and explained the principle of the "pinhole" camera. Having made it plain that light is a *sensation*, and is itself invisible, Mr. Mignard dealt with the subject of refraction, afterwards combining it with dispersion. Newton's famous prism experiment with the resultant spectrum was described, and the solar spectrum analysed. Naturally special interest was evinced in the ultra-violet rays. A careful explanation of the theory of colour, and a comparison of colour in light to pitch in sound, brought the demonstration to a conclusion.

Harlesden and Willesden Photographic Society.—This Society held its first lantern evening at the Court House, Harlesden, on Tuesday last. A large number of slides were shown, being records of members' excursions, snap-shots, &c. A public lantern and musical entertainment was decided upon, the arrangements being left in the hands of the Council.

Putney Photographic Society.—November 21, Dr. W. J. Sheppard in the chair.—Mr. Kidd, of Messrs. Morgan & Kidd, gave a demonstration on *Bromide Enlargements*. He said that bromide printing possessed advantages which practically made it indispensable to amateurs, especially during the winter, when every one engaged during the day must have found the extreme difficulty of obtaining prints by any process requiring our often-absent friend, the sun. Here, then, was an easy way out of the trouble, for bromides could be worked comfortably at our own firesides at night, with light and exposure entirely under control. As regards results, he passed round some prints which certainly would have held their own with the best of any other process. Proceeding with the subject of the evening, he stated that the most suitable negative from which to enlarge was one that was soft and full of detail, but that he had purposely brought one which was a trifle hard, so that members might see how best to get over that difficulty. Having thrown from a three-and-a-quarter-inch portrait negative a 23 × 17 enlargement on the screen, he explained the best method of obtaining a good vignette. In this case he made a pear-shaped hole—about 2 × 1½ inches—in the centre of a piece of thin cardboard, remarking that the mistake was often made of using a vignetting aperture far too large. Moving this backwards and forwards between the lens and the easel, he obtained a remarkably even and delicate vignette. When pinning up the paper, the great advantage of using a yellow glass cap for the lens was clearly shown, as the image was plainly visible, and the operator could therefore see at the very last moment that it was properly thrown on to the paper. He

strongly recommended the ferrous-oxalate developer, the stock solutions for which were made up in accordance with the followlug formula:—1. *Oxalate Solution:* Potash, neutral oxalate, 16 ounces; acid, citric, 1 drachm; hot water, 50 ounces. 2. *Iron Solution:* Iron sulphate (pure), 15 ounces; acid, citric, 1 drachm; hot water, 30 ounces. 3. *Bromide Solution:* Bromide of potassium, 1 ounce; water, 20 ounces. For use take 6 ounces of No. 1 and 1 ounce of No. 2 and a few drops of No. 3; mix in the order given immediately before development. In his opinion this developer gave the purest blacks and whites, and consequently brilliant results. Only such a quantity of bromide of potassium should be used as might be absolutely necessary to bring the developer under control, as an excess would tend to produce greenish tones. The solutions must not be alkaline, and when mixing it is necessary to add the iron to the potash, otherwise a deposit will form and make the developer muddy. With an oxyhydrogen light he gave an exposure of four seconds, and having prepared a developer of one part of iron to six of potash, he proceeded to develop, having first soaked the paper in clean water, and taken care that no air bubbles were on it. A glass bottomed dish was used, as density can better be judged by transmitted than by reflected light. The result was a print that was slightly chalky, and, in order to show how this could be improved, he exposed the same negative for eight seconds, and made up a developer of one part of iron to twelve of oxalate, with bromide as before. The development was now, of course, slower, but the print was decidedly superior to the first, being more harmonious and pleasing. The prints, without being washed, were transferred from the developer direct into a dilute acid bath, made up of one ounce of acetic acid to six pints of water, where they were allowed to remain a few minutes, and being then thoroughly washed in clean water, were placed in a ten per cent. hypo fixing bath for at least fifteen minutes. To obtain the best results, all operations should be carried through as expeditiously as possible, with clean hands and in dishes which should be specially reserved for this process, development being completed before the hypo bath is even mixed. To get rid of the hypo, Mr. Kidd recommended that the print should be taken out from the washing bath and occasionally squeegeed on the back. If this is done, two hours' immersion in running, and about five hours in several changes of still, water will be sufficient. Mr. Kidd now proceeded to make an enlargement of a landscape, with a view to showing how to print in clouds. Throwing the image on the paper, he screened the sky during exposure, taking care to avoid a hard line by moving the shade gently up and down. After soaking, the paper was developed to about two-thirds of the desired density; he then washed the developer well out in clean water, replaced the print on the easel, and printed in the sky from a second negative, now screening the partially developed landscape. The paper being wet, it was less sensitive, and the exposure was therefore proportionately lengthened. The development was then proceeded with until full density was obtained, local treatment being resorted to where necessary. The usual acid bath, washing, and fixing of course followed. Mr. Kidd advised using the lens with as large a stop as was consistent with the covering power, as small stops tend to produce flatness. If properly exposed, the image should be seen in about thirty seconds. The development should be proceeded with until the required density is nearly reached, when the developer should be poured off. It will be found that the print can then be better seen, and development stopped immediately by pouring on the acid solution. After making a few contact prints from negatives brought by members, Mr. Kidd exhibited some fine examples of collotype printing, showing results obtained by his firm's improved collotype method of producing machine-printed ink photographs. He gave an outline of the process, and explained its suitability for producing large numbers of photographic prints at a small cost for all kinds of artistic and commercial purposes. He stated that his firm had one of the largest and best equipped works in this country for carrying on this interesting process. A cordial vote of thanks was given to Mr. Kidd for his lucid and interesting lecture and demonstration.

Richmond Camera Club.—November 21, Mr. F. P. Cembrano, jun., in the chair.—Mr. ANDREW PRINGLE delivered his address on *Different Lantern-slide Processes*. He said he would neither particularise nor demonstrate any of the known processes, but he would simply discuss the theory and the salient points of each one. At the outset he protested against the idea held in certain circles that no artistic result could be obtained in a lantern slide. We all know that some people—principally the followers, not disciples, of a defunct worker—despised and condemned this mode of pictorial representation. He maintained that a slide, properly made and properly shown, was capable of as much artistic feeling as any print. We should not lose sight of the different conditions under which each is seen. One is viewed directly in our hand by reflected light; the other is indirectly transmitted to the eyes by the light of the lantern on the screen. The gradation must be the same in one case as in the other; in other words, it must be equally long in the prints as in the slide *as seen on the screen*. This meant that the scale must actually be higher in the slide itself, because it was viewed by transmitted light, and because the image was enlarged very considerably when projected on the screen. The loss of light being extremely great, the scale of tones must therefore be considerably higher. Judging from his own experience, he had no doubt that most photographers had missed the principal point in this branch of photography. They were under the wrong impression that absolutely clear high lights were an important factor, but such was not the case. The highest lights on the slide should be absolutely clear glass, but they would not show as absolutely white on the screen. The very highest lights, such as represented in the slide by clear glass, should be very sparingly used. It was the enormous expanses of clear skies and superabundance of high lights that had brought discredit on lantern slides. Next in importance were what he would call secondary lights, which are the highest, though *not the very* highest lights in a slide; for instance, a white-washed building, which should not be represented by bare glass, but should show detail. The half-tones were extremely essential in all pictures, whether slides or prints; the detail should be plentiful, and the light moderate, neither too high nor too low. If there was too much light, the *tout-ensemble* would be hard, while, if the half-tones were two low, the picture would be flat. Special attention should be paid to the shadows, as they formed a most important part of the slide. They should be so transparent that all the detail in them should be visible on the screen to a very considerable extent. If an absolutely clear light on the screen was dangerous, great opacity in the shadows was much more so. It was a fact that not sufficient attention was generally given to the general tone of a lantern slide. For his own part, he believed that warm tones were the most desirable; in fact, a perfect slide should, besides the points above referred to, be of a warm, a decidedly warm colour. The tone obtained on a wet-collodion slide toned with platinum was pleasing, but it became wearisome. Cold tones, such as those produced by the ferrous-oxalate developer, were good for scientific subjects, but for artistic work they were very undesirable. He really believed that a large number of cold-toned slides in a lecture produced a cold and fatigued effect on the spectators. Barring toning processes, there was a great danger of over-exposure and fog when attempting to obtain warm tones by development, and increased exposure. This was especially the case with gelatine. Mr. Pringle said that there were two kinds of slides which he would qualify as intolerable: one of them was of the black-and-white sort, such as a snow scene in midsummer, a variety often met with; and the other, which was quite as painful to see, was the result of over-exposure. The lecturer then mentioned the leading characteristics of the various processes most in vogue for lantern-slide work. Beginning with the *wet-collodion process*, he said that the high lights and the half-tones were very good, and the shadows fairly transparent, though liable to too much opacity. If developed rapidly and thin, the results could be modified to a great extent by subsequent intensification. It also possessed the advantage of toning. Some Scotch photographers toned their wet-collodion slides with gold, and, though it was said that slides so toned would not be permanent, he knew that permanency was quite possible if the toning was properly carried out. With regard to the *dry collodion* or *collodio-bromide* process, he was of opinion that it would almost equal wet collodion in the matter of producing transparent shadows and clear high lights. Warm tones could be produced with great ease, and, the exposure being a short one for contact work, and not too long for reduction, he considered this the second best process. The very finest results were obtained by the *albumen process*, but, being exceedingly slow, it was only suitable for contact work. He thought a brief outline might prove interesting to the members. The glass plate was cleaned thoroughly well, and carefully coated with iodised collodion. It was then coated with albumen. The albumen should not be whipped up, and it must be iodised. When in a limpid condition, its hould be poured over the collodion film for about a minute or so. It was then allowed to dry, and here was one of the difficulties of the process, for it was absolutely essential to avoid dust while the plates were drying. The plate is then sensitised in a strongly acid silver bath. The average exposure would be, by contact, about thirty seconds to diffused daylight. The acid pyro developer was the best, and it was preferable to use and to keep it hot during development. The plate was toned and fixed simultaneously in the sel d'or bath. Toning was a great advantage, as any desired tone could be obtained. The *gelatino-chloride* process, although it had produced some remarkably fine slides in the hands of Mr. Cowan, he believed was not the best process for lantern slides. He referred principally to rapid chloride emulsions, in which his own experience was that there was a danger of introducing serious defects in the results. For all-round work, and provided the proper brand of plate was chosen, the *gelatino-bromide* process was the best of all processes. The results were almost, if not quite, equal to those obtained by the other processes, warm tones could be easily got without necessity of fogging, and there was no difficulty in getting good half-tones. He recommended a slow emulsion, and he deprecated one containing a mixture of bromide and chloride or an organic salt of silver. Workers of gelatine plates seldom used a clearing bath, but the lecturer considered that this was a great mistake; in fact, he strongly advocated its use, not only on account of the plate itself, but also on account of the water used in development, which generally left a deposit on the plate. A saturated solution of alum acidified with hydrochloric acid was the bath he would recommend. Although varnishing the slide was not an absolute necessity, still he thought it was an advantage not to be overlooked; the shadows were rendered more transparent, as by altering the molecular surface of the gelatine the varnish allowed the light to go through better. The more nearly the image approaches the appearance of a stain, the nearer will the slide be getting to perfection. Mr. Henderson's argentic stain—which was an emulsion containing an organic salt of silver—had this quality. It printed right out, and could be toned to any desired colour, but sometimes it was difficult to obtain density by this process. As to light for contact work, Mr. Pringle said that magnesium was better than daylight, especially for chloride plates. The lecturer then handed round some specimen slides on albumen and collodion showing some of the points he had alluded to. A member asked the formula for the acid clearing bath. Mr. Pringle replied that he used the following one: Saturated solution of alum, 20 ounces; hydrochloric acid, 2 drachms. The CHAIRMAN said that Mr. Pringle had so thoroughly discussed the matter that he had left him little to say. He agreed with all of Mr. Pringle's remarks, but he thought that, to an experienced eye, a collodio-bromide possessed a quality and a sparkle that were seldom met with in a gelatine plate. Taking it all round, he inclined to think that collodio-bromide was the easiest and the best process for lantern work. Gelatine plates had the great drawback that the colour of the slide very often changed on drying, and he had even noticed a change take place some months after the slide had been made. With regard to the clearing bath, he warned the members that, though very useful, it was liable to spoil a good slide if it was not used with great care. An acid bath containing iron was very good for some slides, as it not only cleared the plate, but would improve the colour of the image. If the plate were left in it for too long, the image would be too much reduced, and the tone too cold. A very hearty vote of thanks to Mr. Pringle terminated the proceedings.

West Kent Amateur Photographic Society.—November 25, Mr. A. R. Dresser in the chair.—It was proposed and carried that the fortnightly meetings be held on Thursday instead of Friday. Mr. C. H. Hastings placed a silver and bronze medal at the disposal of the Judges for competition at the annual Exhibition, January 12, 1892. Mr. GREGOR GRANT read a paper on *Multiple Coated Plates: their History, Use, and Treatment*, in which he followed the various experiments which led up to the invention of the Sandell plate, and those which have been made to test it, showing specimens of the

results of various exposures and the action of the double film in rendering heavy contrasts of light and shade and preventing halation; also some showing the plate's great capacity for standing abnormal over-exposure. Mr. Grant held that, though for ordinary work, where the correct exposure is known, and in cases of great contrast and for interior work, where halation is to be feared, the Sandell plate carries out all that is claimed for it by makers, viz., abolition of halation, capability of rendering great contrasts, and capacity for standing an almost indefinite exposure. Mr. Grant concluded his paper by touching on a modification of the Sandell plate for spectrum photography.

Devon and Cornwall Camera Club.—November 28, the President (Colonel Barrington Baker) in the chair.—The Indian and Colonial set of lantern slides, circulated under the Photographic Society of Great Britain's affiliation scheme, was exhibited. In addition to the above set, several members exhibited, and some very good work was shown on the screen. At the next meeting the subject will be *Developing and Developers*, and demonstrations are being arranged to exhibit the properties of pyro, hydroquinone, eikonogen, rodinal, and amidol. It is also hoped that the series of slides entitled, *Places to be Visited by the Photographic Convention of* 1893" will then be ready, and be exhibited prior to being sent on its travels among the societies. As is probably well known, Plymouth has been selected as the locality for next year's Convention, and the Devon and Cornwall Camera Club, as the issuers of the invitation, hope to secure the co-operation of the townspeople, and of all the clubs in the locality, to the extent at least of a large accession of members to the Convention.

Liverpool Amateur Photographic Association.—November 24, the President (Mr. W. Tomkinson) in the chair.—He referred in feeling terms to the loss the Society had sustained in the death of Mr. J. Noakes, one of the well-known workers of large-size pictures. The SECRETARY read a short paper contributed by Mr. Whitefield, of Manchester, upon his experiments with coloured gelatine for lantern purposes. The paper contained most useful information, which was highly appreciated by those present. Mr. J. SIBETT BROWN then gave a lecture, entitled *A Glimpse of Rome in* 1892, illustrated by upwards of 120 slides made from negatives taken by him in the spring of this year.

Glasgow High School Photographic Society.—November 28, Mr. McCall (President) in the chair.—The subject of the evening was a lantern exhibition by Mr. W. Weir, Secretary. He showed a series of slides, all taken by Shews' hand camera. They embraced Clyde steamers, seascapes, animals, &c.

Hobart (Tasmania) Photographic, Science, and Art Association.—The seventy-fifth meeting of this Association took place at the Museum on October 14. Mr. ROBERT HENRY delivered a lecture on the *Old Collodion Days of Photography*. The lecturer gave practical illustrations in working the "wet-plate process," and exhibited all the apparatus necessary for producing pictures in the old way. Mr. Henry's experience dated back some thirty years, so that he could speak very feelingly of the obstacles which were constantly encountered in picture-making by photography in those early days of the art. Among the apparatus exhibited, a camera made entirely by the lecturer was a capital piece of work, and a beautifully constructed changing box, formerly the property of Bishop Nixon, formed an item for considerable comment.

Cape Town Photographic Club.—Annual Meeting.—The report was as follows:—The number of members at the commencement of the present year was 38. The number of new members admitted during the year is 29, leaving a present total membership of 64. The cash-book of the Club shows as follows:—Balance brought forward from last year, 3*l.* 16*s.* 11*d.*; receipts for the year, 22*l.* 3*s.* 3*d.*; total, 26*l.* 0*s.* 2*d.* Expenditure, 25*l.* 1*s.* 5*d.*, leaving cash in hand, 18*s.* 9*d.* The monthly meetings have been of a most enjoyable character, and have been well attended. The number of the members and visitors present at those meetings amounts to 203, giving an average attendance of 17 persons. On December 15, 1891, Captain Hayes gave an exhibition of lantern slides of animal life, and at this meeting Mrs. Hayes was elected the first honorary lady member. On February 25 last Dr. GILL, the President, gave a most instructive and popular account of recent advances in stellar photography, accompanied with limelight views at the Young Men's Christian Association Rooms. During the past year the following places have been visited by the Club:—Simon's Town, Plattekloip, Groot Constantia, Wynberg (twice), face of Table Mountain, Military Road, Sea Point, and Newlands, and the following subjects have been introduced and discussed at the ordinary meetings:—*Intensification*, introduced by Mr. Wright; *Negatives by Different Developing Agents*, by Mr. Martin; *Mounting of Albumen and Bromide Prints*, by Mr. Wignall; *Reduction*, by Mr. C. Ray Woods; *Enlarging on Bromide Paper*, by Mr. E. Steer; *Isochromatic Plates*, by Mr. R. Pett; *Flashlight Photography*, by Mr. Wignall. At nearly every meeting a large number of lantern slides of views taken by the members have been exhibited, many of them showing great merit. The following were elected as officers for the ensuing year:—*President*: Dr. David Gill, Astronomer Royal (Cape).—*Committee*: Messrs. E. J. Steer, J. R. Wignall, C. Ray Woods, G. van Bonde, R. T. Pett, T. W. Cairncross, D. C. Andrew, and F. Ayres.—*Hon. Secretary*: Mr. A. J. Fuller. A vote of thanks was passed to the retiring Secretary, Mr. G. C. van Bonde, for his services during the past year.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 716. JOHN TAINTON PRIDE, 179, Markhouse-villas, Markhouse-road, Walthamstow, Essex.—*October* 15, 1892.

MY invention relates mainly to photographic hand cameras, and has for its object, first, to provide a bellows body which is capable of being readily extended or collapsed, and which is entirely self-supporting when in the extended position. To this end the invention consists in making the body to fold but once in its length, and so arranging the lines upon which it is folded that the four sides fold inwards towards the centre and meet, or nearly so, when in the folded position. For this purpose two opposite sides (say the top and bottom) fold inwardly upon a transverse crease at the middle of their length, whilst the other two sides fold inwardly along diagonal creases extending from each corner to, or nearly to, a common centre. These sides also have transverse creases corresponding to, and folding with, those of the first-mentioned sides. Instead, however, of all these creases converging to a common centre, it is preferred, to avoid fatigue of the material at this point, that they should connect with a crease surrounding a central uncreased portion of square or other form.

When the bellows body is extended, its four sides are flat and sufficiently rigid to maintain the body in its extended position. In order to collapse it, it is only necessary to slightly press inwards at the folds the transversely folded sides, whereupon the diagonally folded sides commence to assume a concave pyramidal form at same time that by the continued folding of the other two sides the whole body is collapsed and folded upon itself. To permit of this being readily done, the leather body is stiffened with paper or other material in the usual way with lines of weakness where the creases are to come, and a small light-tight air valve or door is provided in the camera front to permit the ready ingress or escape of the air.

The invention relates secondly to the means whereby a number of plates brought in succession to focal position for exposure may be removed therefrom after exposure, and it consists in the combination with two boxes or compartments placed side by side, and destined to contain the plates respectively before and after exposure, of means whereby the plate which has been exposed may be slid through an aperture connecting the two boxes into the other box, thus making way for the next succeeding plate to be brought forward to focal position by a spring behind, whilst the plate so transferred is, by a combination of springs in the second box, caused to assume such a position as to admit of the next plate to be transferred coming in front of it.

The plates are encased in metal sheaths, so that their sensitised surfaces are protected, and the means by which the plates are tranferred from one box to another consist of a bar fitted to slide across the exposure aperture and to bear against the edge of the plate to be transferred, said bar being attached to a longitudinally sliding bar working light-tight in a slot in the frame and provided with an eternal finger-piece for working it by.

The provision whereby the plates are permitted to come in front of one another in the second or receiving box consists of convexly bowed springs, against which the rims of the sheath bear, and by which the plate is forced backwards in the box at same time that it is rocked upon the bowed surface of the springs by the unbalanced pressure or another spring at the back of the plate, so as to readily give admission to the next plate to be transferred.

A sliding shutter is provided at front, and the back of the double box is closed by a rebated lid locked by suitable clamps to give access to the chambers for inserting and removing the plates.

IMPROVEMENTS IN AND RELATING TO CHANGING BOXES FOR PHOTOGRAPHIC CAMERAS.

No. 15,447. AUGUST STEGEMANN, 151 Oranienstrasse, Berlin, S., Germany.—*October* 15, 1892.

MY invention relates to a changing box for photographic cameras, which is arranged in combination with a case designed for depositing the exposed plates. After every photographic exposure, this depositing case is fixed to one side of the changing box. In the adjoining walls are two slots ordinarily closed by slides, so that the exposed plate, when the two slides are in the proper position, can slide from the changing box to the depositing case. The slide may be actuated either by hand through the medium of a special mechanism or automatically. In order that the sliding of the plate may take place after uncovering the slots, the mechanisms provided on the two receptacles, when the latter are put together, set free the foremost exposed plate and separate it from the others, so that it can drop into the depositing case. The two receptacles are in this instance so close together that, during the sliding movement, no rays of light can fall upon the plates. If, then, the depositing case is removed from the box, after the slots have been closed again by the slides, the next plate is automatically put in the proper position in the box for the fresh exposure.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE SENSITIVENESS OF PLATES.

To the EDITOR.

SIR,—May we ask you to be good enough to insert in your next issue the enclosed correspondence regarding an advertisement which has appeared in your JOURNAL? The correspondence speaks for itself.—We are, yours, &c., F. HURTER & V. C. DRIFFIELD.

Appleton, Widnes, November 26, 1892.

[*Copy.*]

Appleton, Widnes, Nov. 15, 1892.

DEAR SIRS,—Our attention has been called to your advertisement in last week's photographic journals, in which you state that your plates have a speed of 100 upon our scale.

We must ask you to kindly inform us upon what ground this statement is based.

Yours truly,
(Signed) F. HURTER & V. C. DRIFFIELD.

To Messrs. The Imperial Dry Plate Company, Limited.

Cricklewood, London, N.W., Nov. 17, 1892.

DEAR SIRS,—Referring to your letter of the 15th inst., we shall esteem it a favour if you will kindly let us know if we are wrong in estimating the ratio between the "Watkins" scale and yours as 3 is to 2, a ratio we believe to be generally accepted as correct.

We are, Dear Sirs,
Yours faithfully,
THE IMPERIAL DRY PLATE COMPANY, LIMITED,
(Signed) T. E. H. BULLEN, *Secretary.*

To Messrs. Hurter & Driffield.

Appleton, Widnes, Nov. 18, 1892.

DEAR SIRS,—We are obliged for yours of the 17th inst., which confirms the conclusion to which we had arrived, that the speed 100 you quoted as the speed of your plates upon our scale was a pure inference based upon Mr. Watkins' estimation.

Whatever connexion Mr. Watkins may have stated to exist between his speed and our own has never in any way been acknowledged by us, nor have we ever given a thought to the subject, for the simple reason that Mr. Watkins has no system of speed determination beyond that open to every photographer, namely, camera test. We cannot, therefore, for one moment admit his speed as a basis upon which to estimate ours. Our own method of speed determination is the outcome of years of laborious investigation, especially undertaken with a view of superseding camera tests. It is based upon actual measurements of the work done by the light, and is provided with a scientific nomenclature and system of units.

From what we have said, we think you will allow that we are justified in objecting to plate-makers using our names at all, unless they actually adopt our system. Such a course is clearly calculated to mislead the public, who naturally infer, when the speed quoted is associated with our names, that it has been ascertained by our methods.

Should you at any time care to adopt our method yourselves, you may count upon our cordial assistance, and we trust you will regard what we have said in the friendly spirit in which it is offered. We do not for a moment imply that your plates may not reach a speed of 100 upon our scale, but it is in the highest degree improbable that this figure accurately represents their speed.

We should like, with your permission, to publish this correspondence, including any reply to this letter you may care to favour us with, as we think it may prevent misunderstanding in the future, and that it is only fair to those makers who have adopted our system to take this course.

Yours truly,
(Signed) F. HURTER & V. C. DRIFFIELD.

To Messrs. The Imperial Dry Plate Company, Limited.

Cricklewood, London, N.W., Nov. 21, 1892.

DEAR SIRS,—In reply to your letter of the 18th inst., we have somewhat anticipated your reply, having withdrawn your names from our advertisements, it being far from our desire to have a controversy with you or prejudice you in any way.

You are, however, doubtless aware that plates are now in the market branded with a certain number on your scale, and "EQUAL TO —— ON WATKINS'." Statements to the same effect can be found in photographic literature every week, comparisons being made, as one would between Fahrenheit and Réaumur or Celsius.

We cannot, therefore, see that the publication of the correspondence that has passed between us would help to solve the question whether 150 Watkins is equal to 100 Hurter & Driffield.

Should you decide to publish our letters, we should probably let the manufacturers, who are pledged to one or *both* systems, discuss the matter.

We are, Dear Sirs,
Yours faithfully,
THE IMPERIAL DRY PLATE COMPANY, LIMITED,
(Signed) T. E. H. BULLEN, *Secretary.*

To Messrs. Hurter & Driffield.

Appleton, Widnes, Nov. 24, 1892.

DEAR SIRS,—From your letter of the 21st inst., we gather that you have failed to understand the position we have taken up.

We have no objection whatever to plate-makers who have adopted our system deducing the Watkins' speed from ours, but we do object to our speed being inferred from Mr. Watkins'.

Our object in publishing this correspondence has nothing whatever to do with deciding what relationship exists between Mr. Watkins' plate number and our speed, but simply arises from a desire to do justice to those plate-makers who have taken up our method, and who are earnestly striving to carry it out impartially and thoroughly.

Furthermore, in the interests of the photographic public, we consider that any quotation of our speed should be based upon an actual determination, and not upon an inference.

In conclusion, we again ask you to accept the assurance of our goodwill, and we remain,

Yours truly,
(Signed) F. HURTER & V. C. DRIFFIELD.

To Messrs. The Imperial Dry Plate Company, Limited.

MESSRS. HURTER & DRIFFIELD'S PAMPHLET.

To the EDITOR.

SIR,—In consequence of an alleged paragraph in your JOURNAL stating that this Society supplies copies of Messrs. Hurter & Driffield's pamphlet on the testing of the sensitiveness of dry plates, I am receiving applications for the pamphlet from several quarters.

It will save disappointment if you will inform your readers that the above statement was made under a misapprehension, and that the Society of Chemical Industry possesses no copies whatever of Messrs. Hurter & Driffield's papers save those inserted in its own journal, which is not on sale to the public, but is reserved for its own members and yearly subscribers.—I am, yours, &c., CHARLES G. CRESSWELL.

Society of Chemical Industry, Palace Chambers, 9. Bridge-street, Westminster, S.W., London, November 25, 1892.

RE MOUNTING AND BURNISHING GELATINO-CHLORIDE PRINTS.

To the EDITOR.

SIR,—As your correspondent pointed out a fortnight ago, little or nothing has been said about the means to be adopted for pressing wet gelatino-chloride prints into contact with the mounts. Ordinary blotting-paper is unsuitable as it leaves the fluff behind, but there is a blotting-paper, manufactured, I believe, in Manchester, that is "just the thing;" as you will see from the piece enclosed, it is a hard, close-grained paper, without fluff, and quite smooth on one side.

For professional use, gelatino-chloride paper should be treated in precisely the same way as albumenised paper. The separate toning and fixing baths should be used, no matter what the brand of paper, and an alum bath should be used after toning and before fixing, the prints, of course, getting a short washing between the different baths; final washing should be confined to two hours.

Prints on this paper burnish far better than albumenised; they take a beautiful gloss, but, instructions to the contrary notwithstanding, they should be lubricated by rubbing them with a little Castile soap dissolved in methylated spirit, *especially when using a bar burnisher.* If enamelled prints are required do not squeegee them on to hare glass, except you want to become prematurely grey; if the plates are collodionised, everything goes on castors, and the prints are protected from damp or dirty fingers, &c.—I am, yours, &c., T. FITZGIBBON FORDE.

Fallowfield, Manchester, November 18, 1892.

P.S.—When mounting have a piece of damp sponge at hand to remove dust, starch, &c. Tongues off, please.

DENSITY IN COLLODION EMULSION PLATES.

To the EDITOR.

SIR,—Allow me to thank Mr. W. B. Bolton for his kind and exhaustive reply to my queries respecting the above; it is most interesting, and I am sure will be appreciated by many other readers of your invaluable JOURNAL besides myself.

The point certainly opens up, to me, a new light on collodio-bromide emulsion making, that referring to withholding part of the bromised collodion, and sensitising the remainder with the full quantity of silver. There are one or two other remarks in Mr. Bolton's reply I should like to refer to with your kind permission. First, with regard to bromising, I may say that I have kept the bromised collodion three weeks *before* sensitising, but I have always maintained an excess of bromide up to the period of washing, allowing sometimes two or three weeks to ripen before washing; in all cases I have dried the pellicle *bone dry*, on account of the danger Mr. Bolton refers to. With regard to the bromide, I usually add the dry double salt to the collodion, but do not get all to dissolve; this is caused, I believe, by crystals of the salts becoming encased, as it were, in a skin of collodion, but I find, as Mr. Bolton says, it is easily dissolved in alcohol alone. And this plan I shall adopt in future, together with the hint to sensitise half of the bromised collodion first, and then to add the remainder. I have not hitherto adopted this plan, as I was always under the impression that, for emulsion of the highest

quality for transparencies, the silver should *never, at any time*, be the slightest in excess.—I am, yours, &c., J. R. G.

Mytton Hall, Shrewsbury.

THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the EDITOR.

SIR,—At the present time we have on the books of the Employment Bureau connected with the Benevolent, the names of many assistants for whom we see little probability of finding work this winter. We have one or two wet-plate men who do well in the summer time, who are hard working and economical, but who cannot tide over the whole of the winter. These, and some other men who are printers, would be glad to accept almost any situation in which they could earn a living. Some of them would take places as packers, light porters, &c. At present there seems to be very few vacancies for assistants, though we could find a first-class position for a thoroughly good wet-plate lantern slide maker. On the books we have a considerable variety of almost all classes of general assistants. In one or two cases of men for whom we have found outdoor employment, where we could not obtain them indoor work at their proper branches, the poor fellows are in need of good boots and weather-proof overcoats, which their reduced circumstances and small salaries in their temporary positions hardly enable them to purchase. If any of your readers have "cast offs" in these two lines I should be glad to have a post-card offering them. I would rather not have the things sent on at once, because, in some such cases, the contributions come to hand in greater quantities than the need requires, and it would be a pity for us to accumulate clothing which is needed for other charities.—I am, yours, &c., H. SNOWDEN WARD, *Hon. Secretary.*

Memorial Hall, E.C.

Exchange Column.

* *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Gent's diamond ring, cost 7*l.*, for a lens by good maker.—Address 107 Lake-road, Portsmouth.

Wanted, rolling machine, cabinet size; will exchange burnisher, nine-inch roller.—Address, J. DAY, Photographer, Hendon.

Will exchange 8×7 feet exterior background, on rollers, for four-inch double condenser.—Address, G. MOORE, Backfastleigh, Devon.

I will exchange a cabinet burnisher, new, for a studio curtain or a retouching desk.—Address, JOS GOTHARD, Photographer, Heckmondwike.

I will exchange a fireplace accessory and ½-plate landscape lens for interior or graduated background.—Address FRED. C. D. HURD, Shepton Mallett.

I will exchange guitar, in case, for embossing press, cabinets and *cartes* for enamelling.—Address, L. H. GRANT, 2, Bowdley-street, Clapton-park, London, N.E.

Lerebours full-plate and Dergy's quarter-plate lenses, in exchange for cabinet lens by good maker.—Address, J. ARTHUR, 65, Dale-street, Batley Carr, Yorkshire.

Wanted, Ross or Dallmeyer's 3 a portrait lens; will exchange Seavey's backgroonds and accessories to value.—Address, HERBERT WATKIN, Grand Studio, Scarborough.

Will exchange 8½×6½ rapid rectilinear by Sands & Hunter for 8½×6½ wide-angle or mid-angle rapid rectilinear.—Address, J. AVERY, 45, Prince of Wales'-road, Kentish Town, N.W.

Wanted, 5×5 Optimus euryscope lens, with Iris diaphragm, in exchange for 5×4 quick-acting portrait lens by Ross.—Address, WILLIAMSON EMSLEY, Whitelands, Rawdon, near Leeds.

Will exchange quarter-plate portrait lens, with rack and pinion, or Grimston shutter full size, for four of Bennett's dark slides, whole-plate size. Address, H. JACKSON, l'photographer, Fishguard.

Will exchange Hember pattern pneumatic safety, balls all over, condition as new, cost 19*l.* 19*s.*, for whole-plate set and cash.—Address, H. G. DORRETT, 132, St. John's-hill, Wandsworth, London, S.W.

Will exchange "Harrison's" head and body rest and baleony in four pieces for quarter-plate detective camera (Facile preferred), or whole-plate camera, three double dark slides.—Address, T. R. ALLANSON, Esplanade Studio, Bridlington Quay.

Wanted, a Lancaster half-plate Instanto in exchange for any of the following:—Stereoscopic camera, with five double slides, and a pair of Dallmeyer lenses; Archimedean studio stand; or a forty-feet hydrogen cylinder.—Address, L. DIXON, Market-street, Colne.

Will exchange new 12×12 Vever's burnisher, Ross's 10×10 mahogany camera, Marion's flywheel *carte-de-visite* embosser, for posing-chair with movableiacks and universal balustrade, or flower-stand.—Address, J. HORTON, Central Studio, Caroline-street, Cardiff.

Exchange McKellen's Treble Patent Camera, 22×19, three double slides, turntable and tripod, never used, cost 40*l.*, for complete stereoscopic outfit, large burnisher, or other photographic apparatus up to value, about 20*l.*—Address, J. PICKLES, Engineers, Hebden Bridge.

Wanted, hand camera, quarter-plate or 3¼×3¼, rapid rectilinear quarter-plate lens, or condenser for enlarging, nine or ten inches diameter; exchange for a quarter-plate camera and three double backs, Ross' half-plate wide-angle rectilinear, Grubb half-plate view lens.—Address, J. MARTIN, Southwold, Suffolk.

WEST LONDON PHOTOGRAPHIC SOCIETY.—December 6, Technical Social Meeting.

PHOTOGRAPHIC CLUB.—December 7, *Retouching*, by Mr. Redmond Barrett. 14, Members' Open Night.

WOOLWICH PHOTOGRAPHIC SOCIETY (St. John's School, Wellington-street).—December 8, *Printing-out Paper*, Mr. J. Howson.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. — December 8, Members' Open Night. 15, Monthly Lantern Night.

PUTNEY PHOTOGRAPHIC SOCIETY.—December 5, Mr. A. R. Dresser on *Work with a Hand Camera*. Lecture illustrated by lantern slides.

ALDENHAM INSTITUTE CAMERA CLUB.—Tuesday, December 6, continuation of lecture by Mr. A. Hair, *The Human Eye as a Camera Obscura*.

CROYDON CAMERA CLUB.—December 5, *The Glycerine-oxalate Development of Platinotypes, and Platinotype Printing by Artificial Light*, Mr. W. H. Smith. 19, Lantern Night (members' slides).

RACK-WORK LENSES FOR HAND CAMERAS.—Of course, the application of rack work to a lens is coeval with lenses themselves; but Messrs. Taylor, Taylor, & Hobson are about to make, if they are not now actually making, a speciality of such lenses for hand-camera work. These contain in themselves the focussing gear, the focussing scale, and the iris diaphragm. This will, doubtless, prove very convenient in many cases.

ON Thursday evening last, the 24th inst., the workpeople employed at Mr. Eddison's various branches, viz., Leeds, Sheffield, Barnsley, and Castleford, held their fourth annual dinner and social evening at the Co-operative Hall, Barnsley. Mr. Eddison presided, and over fifty of the *employés*, with several of their friends, were present. At the close of the dinner the usual toasts were proposed to the host and hostess, &c.

THE BENEVOLENT.—A meeting of the Committee of the Photographers' Benevolent Association was held on November 24, Mr. A. Mackie in the chair. Four applications for relief were on the agenda. The thanks of the Association were unanimously accorded to the Photographic Society of Great Britain and Mr. Frederick Hollyer for their generous contributions to the funds. The Secretary reported that an application for advice and legal assistance had been received in a case of alleged illegal discharge. He had put the matter in the hands of Mr. Tabrum, who had promised to advise and to take such other steps as should seem necessary. Dr. Lindsay Johnson and Mr. Frederick Hollyer were elected Life Governors of the Association, as some small acknowledgment of the assistance they had recently rendered to it.

PHOTOGRAPHY IN AUSTRALIA.—A correspondent writes: "I had hoped to have been able to give a good account of the progress photography had made since I left the colony some six years ago. Unfortunately, however, a most remarkable depression has fallen on the entire Australasian group, brought about by a reaction after the collapse of the great land boom and violent speculations into which everybody seems to have been more or less drawn. The result is that the greatest distrust now exists, business is paralysed, and ruin is everywhere. When I tell you that seventeen millions of money, savings of the people, are locked up in financial institutions that may take ten or twelve years to liquidate, you can easily imagine the want of go apparent everywhere. It is quite impossible to say how long this state of things will continue, but we all hope that with a big harvest, and good wool season, things will soon take a turn. On return, I found our photographic society all but dead. Its funds were in an institution that had closed its doors, and it was next to impossible to collect subscriptions. After some twelve months, during which time scarcely a meeting was held, a few of us are endeavouring to resuscitate it, and, by lowering the subscription from one pound to five shillings, we hope to meet the times, and again have a good membership roll. Since I left I find much competition has gone on in trade, prices are lower, and almost every novelty is now obtainable; in fact, it is unnecessary to bring stocks of plates, films, &c. Photo-mechanical processes are well forward, many newspapers using various processes in illustrating. A firm of printers in business at Ballarat (a large goldfield town) turn out some splendid work for advertising media, book illustration, and the like. The professional portrait saloons, although turning out, if anything, better work than usual, are very dull of business, and prices have consequently suffered."

Answers to Correspondents.

R. D.—See editorial article in this present number.

BELLA.—The albumen paper has been tinted with an unsuitable dye.

HERBERT.—Some of the Edinburgh lamps fulfil the conditions required.

C. C. W.—We have forwarded your query on to the writer of the article.

W. K. BURTON (Tokio).—Received. Many thanks. The matter will now be closed.

W. VICK.—The details of Mr. Van der Weyde's photo-corrector have not been published.

G. E. HADDEY.—You will find the subject of photogravure spoken of at some length in our forthcoming ALMANAC.

E. HERBERT.—One light of from 5000 to 6000 candle-power would suffice, with a couple of reflectors, one of them being utilised to soften the shadows.

T. B. CLIFTON.—One of the best preventives of blisters on albumen prints we have tried is that of Mr. Richmond, namely, to immerse the prints after printing, before they are wetted, in methylated spirit, then wash, tone, and fix in the ordinary way.

TYRO.—Judging by the definition of the three specimens, you have evidently obtained an excellent lens. The focus is quite suitable for a half-plate. The shutter may be placed either in front of or behind the lens. It is purely a matter of convenience.

E. G. M. asks: "Would you kindly inform me what gum is used with the black or Indian ink for finishing bromide enlargements, that is, for glazing and deepening the shadows, and stippling the background?"—A solution of gum arabic is what is used for the purpose.

T. WALDEN.—We are always willing to oblige our readers, but must draw the line somewhere. We cannot undertake to analyse mounts to see if they contain matters that might act perniciously on silver prints. To do this completely is a matter of hours, sometimes even days.

STUDIO.—With that width of studio, we should recommend fourteen feet of glass at the top and sides, as it will then be more convenient for taking large groups when required. The glass might also be continued one foot lower at the sides with advantage—that is, if we understand the sketch rightly.

B. A. (Cambs.).—If a portrait lens of the Petzval form will not give a sharp image on the screen at any part, unless it is stopped down to *f*-16, it must be a very defective instrument. It should give perfect definition over a good portion of the field with its full aperture. Are the glasses properly arranged?

G. P. S.—It is not to be wondered at that the inspection of the group pains the eyes of those who examine it in the stereoscope. If you look at it again (it is returned as requested), you will find, although it is mounted so squarely, the two halves are so trimmed as to cause the figures on the left-hand picture to occupy a level higher than the right-hand side by nearly a quarter of an inch. By retrimming them all will be right.

R. W. (Newcastle) puts the following query: "I have some photographs which have been stained with salt water (sea water), which has caused red markings upon them. Can you tell me how I can remove the stains without injuring the prints?"—It is doubtful if the stains are removable without injury to the prints, or without knowing what has caused the stain in addition to the sea water, as we suspect that alone has not done the mischief.

C. SHULTZ (Frankfort).—We can scarcely advise you in the matter. We can, however, tell you that there are a very large number of skilled operators, as well as retouchers, out of employment in this country at the present time, and doubtless they, unfortunately, will be for some months to come. Professional portraitists here attach very little importance to technical class diplomas; they prefer practical proof of competency in the studio.

COLLODION.—I. Edge the plates with a solution of indiarubber. 2. We are at a loss to account for your failure in getting sufficient density with the acid pyro and silver intensifier. We have never such a failure ourselves. 3. Give a full exposure, and use a well-restrained developer. Probably the veil of which you complain would disappear if the picture were varnished with an ordinary spirit varnish. 4. Such an emulsion should keep well for several months.

S. V. W. says: "I shall be obliged by your telling me how I can make some ozone bleach, which is not now a trade article. It is, I believe, a hypochlorite, but I am no chemist, and do not know of what, nor how to proceed to make it, although I have understood that it is easy to make."—It was probably a sodium hypochlorite, of the preparation of which we have been unable to obtain details. Perhaps some reader may be able to supply the desired information.

F. C. Green, of Chihuahua, Mexico, writes: "Will some of the readers of your Correspondence Column better versed in chemistry than I am kindly explain, if the theory of Captain Abney and of other authorities, that the action of light on Ag Br is to reduce it to a lower order, setting bromine free, is correct, why, on volumetrically testing the purity of a bromide by means of Ag NO_3, the result is not higher when the operation is conducted by daylight than in a dark room? Can the nascent bromine not decompose the Ag NO_3?"

AMATEUR writes: "I have built a studio in my garden thirteen feet long. Will you please tell me of a cheap lens that will take full-length cabinet portraits in it that will be free from distortion? The only lens that I have that will take a full-length picture in the studio is a wide-angle one, and with it the perspective is far too violent."—No lens will do what is required in that length of studio. The best plan will be either to lengthen the studio or make such alteration as will permit of the camera being placed outside the room when full-length pictures are desired.

S. A. S. says: "Nearly two years ago I was compelled to pledge a valuable lens. A short time ago I went to redeem it, and I was told that it was sold by auction in the ordinary course, and probably it was sold, under these conditions, under its value. Have I any redress?"—No, except that you can demand to see the pawnbroker's books, and, if the instrument realised more than the amount it was pledged for, with the interest and expenses of sale, the excess will be your property. If, on the other hand, it did not realise that amount, you are indebted to the pawnbroker for the deficit.

A. W. says: "I had a Daguerreotype brought to me to copy, but it was covered with a brown stain which rendered it impossible to get a good copy from it. Having read that Daguerreotypes could be cleaned, I immersed it in diluted nitric acid, and it has removed the brown stain, but the image is gone too. Can it be restored? and, if nitric acid is not the right thing to use, what is?"—The Daguerreotype is now past restoration. If, instead of treating the picture with nitric acid, a dilute solution of cyanide of potassium had been employed, it might have been restored to its pristine condition.

INQUIRER writes: "Can you tell me whether the stains on the enclosed photograph are owing to imperfect washing of the print or to impurity of the mount? The photograph was mounted with freshly made starch. I have had a large number go like this, and cannot fathom the reason."—The prints show unmistakable evidence of fading, but whether this is due to imperfect washing, insufficient fixing, or faulty mounts, it is impossible to say by a mere ocular inspection. To ascertain if the mounts were at fault, a chemical examination of them would have to be made, and this our time will not permit us to make. The mounts had better be sent to an analytical chemist for examination and report. If that says the mounts are pure, the cause of the fading must be due to the manipulations.

G. MOORE writes: "I am often now puzzled to know why my print washings won't precipitate. I keep a large, wide-mouth jar that holds about two gallons, and when full, add hydrochloric acid. This time, however, it won't settle, although I have used both acid and salt (sod. chl.). Could you suggest anything? I fancy I have observed a greater reluctance in the settlement of the silver chloride since I began the use of gelatino-chloride paper, as, if I recollect rightly, the albumen paper washings settled readily."—With the treatment mentioned, the chloride ought to settle down. We know that sometimes it does not do so readily with ready-sensitised paper. Often, if the whole is stirred up violently two or three times during a day, it will quickly subside. Exposure to light also favours subsidence.

ANXIETY.—Both technically and artistically the photograph is excellent. Respecting the spots, the mount seems all right, and we would not hastily feel inclined to blame it until after a prolonged comparison between some that were mounted and others left unmounted. We know of a similar instance in which the photographer ran such spots to earth, and eventually found that they were directly traceable to the employment of a particular sample of hyposulphite of soda, upon changing which the spots never again troubled him. Should this not prove a remedy in your hands, then test the mounts by pressing a moist print, face down, upon a dry mount, previously interposing a slip of pure white paper to isolate a portion of the figure from the mount. After a few days strip them asunder and note what change, if any, has taken place.

ELECTRIC writes: "Can you give me any information as to the probable cost of introducing electric light into my studio for taking portraits? I don't mean to make the electricity myself, I can get that from the electric lighting company. Will you tell me what appliances are required and the probable cost? and also are the appliances cumbersome, or will they be in the way when using ordinary daylight? My studio is small, and I have not much room to spare. I enclose a plan of my studio, so you will see what room I have to spare."—By applying to the electric lighting company they will give an estimate for what is required. All that is necessary is an arc light of from five to six thousand candle power, and a reflector such as has so often been described. The whole affair is by no means cumbersome, and can well be fitted in a studio of the form and dimensions shown in the sketch.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—Meeting of delegates, November 26, Mr. W. Bedford in the chair.—The report of the Committee on Technical Lectures was read, to the effect that Photogravure seemed the most suitable subject. The members of the Committee stated that they had approached the Photographic Society of Great Britain, who had given them a favourable reply, and that they were in communication with a probable lecturer. The report was adopted. To carry the proposed lectures into effect it was proposed by Mr. Cox (North Middlesex Photographic Society), seconded by Mr. Clifton (Photographic Club), and carried, that a committee, to consist of Messrs. Everitt, Hodsoll, and Marchant, be appointed to elect a lecturer and to report upon the best method of carrying out the scheme. A letter from the Southsea Photographic Society was read suggesting, 1, a means of circulating for fixed periods the more expensive works of reference on photography amongst the Societies; 2, That albums should be collected and circulated illustrative of the best work of the various Societies; 3, That sets of slides should invariably be accompanied by readings. With reference to the first proposal, which was that the Committee should subscribe to some library where the works were to be found, it was pointed out that no such lending library existed that the delegates present were aware of, and that the formation of a circulating library would be impossible in the present state of the funds at their disposal. The second suggestion, on the proposal of the Chairman (Photographic Society of Great Britain), was adopted in the form of an invitation to the various Societies to form albums illustrative of various printing methods, &c., which it was thought would prove of considerable interest. The Secretary was instructed to communicate in the above matters to the Societies affiliated, and to draw their attention to the desirability of reading matter being supplied with the slides for circulation.

FORTHCOMING EXHIBITIONS.

1893.	
February 18.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb, 100 High Holborn, E.C.

MAGNIFYING GLASSES FOR RETOUCHERS.

Retouchers who are shortsighted in even the slightest degree are able to practise their art without having to invoke any lenticular aid. But men of this class are in a minority, most retouchers preferring to make use of a magnifying glass for enabling them to work effectively upon the fine details in a portrait photograph.

One retoucher informed us that he always made use of a single magnifying lens of four inches diameter, which was attached to his retouching desk by an adjustable arm. The focus was eight inches, and the lens was thick, heavy, and cumbrous. We tried to convince him that precisely the same magnifying effect could be obtained by employing a pair of spectacles, the lenses in which were of the same focus as his large reading glass. This he promised to try, as the convenience would be great in comparison with the heavy lens spoken of.

After some time he reported that he had tried the glasses recommended, and had failed with them. When looking through any one of them he said he could not perceive any difference in magnifying power between it and the four-inch reading glass, but when both eyes were employed a great difference was immediately appreciated. With the large magnifier, the eyes rested insensibly upon the part of the negative desired to be examined, and this was altogether unaccompanied by any straining, while with the two smaller glasses the coalescence of vision on one part was only obtainable by a considerable ocular effort accompanied by a slight pain induced by such effort. The cause of, and remedy for, this difficulty we shall now point out.

When both eyes are directed each through the centres of similar lenses, if the foci of these be long, then will an object at a reasonable distance, say, from twelve inches upwards, be visible without any muscular effort; but, in proportion as the foci of the pair of lenses become shortened, so does the difficulty of seeing increase, until, at a very short focus, one cannot see an object with both eyes at all. True, by either eye it will be seen quite distinctly, and magnified to a more or less considerable extent, but by no muscular effort can both eyes be used simultaneously. This is the case when the centres of the lenses are directly opposite the centres of the eyes.

Let the lenses now be decentred, by any mechanical means, so as to bring their centres a little closer together than the width of the eyes, and all straining in order to see distinctly is obviated, vision becomes distinct with both eyes, and through the spectacles becomes identical with that through the large magnifier—so far, at any rate, as concerns its application to the requirements of the retoucher.

For here is what takes place. In the large lens, and by virtue of its dimensions, neither of the eyes can be directed through its centre, but must necessarily be opposite a portion near the margin, and which forms a prism that bends the rays from the eyes towards the axis at the other side. Hence the facility with which a central object can be examined by a large lens. Now, when the glasses of the spectacles are decentred in the manner spoken of, they are placed in a position precisely analogous to the single large magnifier—that is to say, the eyes are directed not through their axes or centres, but through a portion much nearer their margins, and hence forming prisms by which the rays are deflected. It is indeed precisely the converse position of eyepieces for the stereoscope, in which the conditions to be fulfilled are of an entirely opposite nature.

The adoption of the system here suggested will, we believe, prove convenient and useful to retouchers, especially those who from necessity or choice make use of magnifiers having a considerable degree of power.

RECENT EXHIBITIONS AND THEIR LESSONS.

The last three months have been a glorious time for the photographic pot-hunter, no less than nine exhibitions with open classes having provided him with the means of indulging in a variation of the pastime associated with the name of the metaphorical and mysterious individual, Tom Tiddler. There has, of course, been the usual up-and-down element in the distinctions conferred in various places and by various Judges upon peregrinatory exhibits; the customary flood of disgust and disappointment of dissatisfied competitors has also broken loose, while in some cases it is feared features of a decidedly objectionable nature have been associated with more than one of the exhibitions. It is, in short, useless to affect ignorance of the fact that widespread discontent prevails among exhibiting photographers and the photographic public with the management of exhibitions, the curious contrariety of opinions expressed by different Judges, the uncertainties of Judges powers, the absurdities and injustices they are the means of imposing; and with what is called the "medal system" and exhibition matters generally.

If the high-handed proceeding of the Judges at the Tunbridge Wells Exhibition, in withholding awards wholesale, has done nothing else, it has at least compelled an attention to the subject of photographic exhibitions, which should not be relaxed until some common agreement has been arrived at on many points of critical interest.

The desire on the part of the individual for a permanent expression of his success in competition with his fellows is such a deeply rooted trait of human nature that it is as idle to dis-

cuss the question of abolishing medals at photographic exhibitions as it is to cast ridicule on the Prix de Rome, the Royal Society medals, or even military medals. Honour, in nineteen cases out of twenty, is valueless unless symbolised in the concrete, and a bare recognition of this unmistakable truth is sufficient to put to silence any objection to medals and other awards at photographic exhibitions. For we take leave to say that, without such public competition, exhibitions of photographs would be difficult, if not impossible, to maintain; and, since it is highly probable that progress in technical and artistic photography largely relies for recognition and encouragement upon the opportunities for expression and publicity which those exhibitions afford, it not unnaturally follows that photography itself would not inconceivably suffer by the suppression of the competitive element in exhibitions.

Admitting this much, several questions of vital interest inevitably thrust themselves into notice. The first one is, Who shall be the judges of relative merit at photographic exhibitions? The answer, according to most of those who promote these exhibitions, would appears to be, Those who have themselves been successful exhibitors. An obvious fallacy, if modern thought and practice be accepted as a guide, underlies the theory here implied. Art critics are not usually painters; dramatic critics are seldom, if ever, playwrights or actors; reviewers do not habitually write books; the occupants of the bench are not advocates. By what train of reasoning, therefore, do photographic society committees so habitually reach the conclusion that successful exhibitors at photographic exhibitions are the most competent to decide upon the merits of the pictures of those against whom they have themselves, and may again, compete? Again, it were vain to pass over the important circumstance, that artistic photography of the present day is in process of evolution into two or more schools, with whom focal treatment, methods of printing, selection and composition are matters of interesting disagreement and controversy. Shall, then, the adherents of the one school be the Judges of the works of the other in competition with those of its own?

If the Judges of photographic exhibitions were drawn from the ranks of those who were not themselves exhibitors, there would be less chance, we submit, of individual idiosyncrasy controlling the disposition of the awards. To what extent, moreover, should Judges have power to fix a standard of merit, or to withhold medals? In our opinion the one should not be placed within their province, while the other should not be permitted them so long as the conditions laid down by the promoting society have been complied with. To place such powers as these without limitations in the hands of Judges who are themselves occasionally competitors is to pave the way for all sorts of grotesque proceedings and equally invidious comments upon them. Where an exhibition is organized under promises to the competitors of the award of a certain number of honours, and the latter are withheld by the Judges on grounds which they themselves set up, the competitors are cheated, the society itself is insulted, and the whole business is covered with ridicule. It is, in fact, promoting an exhibition on very like false pretences.

We have referred to pot-hunting. Merit, wherever it appears, should be recognised; but is it not permissible to utter the sentiment that a man who shows surpassing excellence should not thereby be permitted to sweep the board of all the prizes on offer, but that he should be subjected to certain limitations as to the number of medals he can grasp? Why are champion classes not more generally held? Is it, again, strictly honest on the part of exhibitors to change the titl of their "touring" pictures now and again? Are Judg always given sufficient time and opportunity for arriving their awards? Should technical faults be overlooked, ar artistic excellence alone considered? What powers is it advi able to confer on Judges as to the bestowal or withholding awards? In the latter case, should their reasons not always stated? Should they be expected to enact the *rôles* of criti as well as Judges?

These are only a few among the questions which have bee suggested to us by a study of recent exhibitions, and we pla them here in the desire to afford an opportunity for discussio by those interested. The whole subject of the conduct photographic exhibitions is ripe for thrashing out and settl ment on a basis of common agreement, and we trust that son authoritative action will be taken in providing a standard s of rules for societies, exhibitors, and Judges alike. Could n some member of the Photographic Society of Great Britai move that body to appoint a Committee to deal with it?

BACKGROUNDS.*

In reference to the plan of making the feet of supported frame backgrounds to project on one side only, it has been suggeste to us that, where only two or three are in use, it would b better to have two feet on one side and one on the other, an thus the maximum of stability would be retained, witho there being any danger of the whole falling over in consequen of some untoward push. A couple of grounds would "nest equally well, and one extra framework would not seriousl interfere with the length of the studio. We repeat the hi for what it is worth, appearing, as it does to us, a simple an practical plan.

Treating now upon the actual use of these almost necessar adjuncts, several points arise which have not hitherto bee publicly discussed. First, we have the question of architec tural scenes, interior or exterior. It must have offended th artistic instinct of many photographers to see, as is often th case, sloping perpendiculars—columns emulating Pisa's cel brated Tower, side windows made by errant carpenters, an buildings whose appearance would shock an architect, an many similar eyesores. It need scarcely be said that thi is owing to the inevitable tilt given to the portrait camera i bringing the figure centrally upon the plate. To correct b using the swing-back is to bring the feet of the sitter out c focus, and thus render necessary so small a diaphragm as t seriously interfere with the sitter's comfort. With hangin backgrounds there is no other remedy; but, when these ar stretched on frames, the difficulty is surmounted in th simplest manner. All that is necessary is to tilt the frame work backwards until it is parallel with the camera back; th parallelism of the verticals will then be retained, and there wil be least disturbance of focus.

We have said that this cannot be done with hanging back grounds, and this is true in the strict sense of the words; bu there is here also a remedy, and one which carries certai advantages in its track. Whether the rolling scenes be used singly, or in one of the frameworks we have alluded to, i would be quite possible to interpose a permanent stiffened framework covered with canvas, rendered taut with a coating or two of wall paper, behind the background. This framework could then be tilted, and the scene would take the same angle.

* Concluded from page 754.

The very great advantage that would attend the use of this movable "wall" would be the possibility, where the object represented was an interior or exterior wall or any solid object, of greatly extending the possible range of poses by permitting the sitter to lounge or rest against the protected background. Many extremely natural positions can be attained in this manner which are quite impossible with a loose hanging canvas. No one, we imagine, would be content to take a portrait when the sitter's elbow, for instance, caused an apparent break in the wall. The slightest disarrangement of the perfect flatness of the background would at once destroy all pictorial illusion; the figure would be backed with painted canvas, and not with a sketchy, suggestive scene. It will be scarcely necessary to interpose the remark that this leaning against a stiffened background could only be permissible in the case of solid objects, though it must be admitted that it has not infrequently happened that portraits have been sent out where the figure has cast a shadow on the sky, for instance!

This point leads to another little-understood matter—the position of the background in relation to the light. Many photographers have purchased backgrounds from seeing the dealer's photographs of them, but have been greatly disappointed in not being able to obtain the same effect; however used, the scene comes up darker or lighter than the original represented it. This is entirely owing to combined causes of the angle at which they are placed with regard to the illumination, and the amount of light admitted through the studio windows upon the background itself. A sitter is taken with one of these views behind, and all goes well; another sitter immediately following is photographed with the same surroundings, but when the print is scrutinised the ground is dark, heavy, and unnatural. The reason is simply that the blinds have been altered to suit the requirements of the features of the second sitter, and the light received by the ground has been entirely changed in quantity.

A most valuable quality of the movable frame, whether of rapid frames or sets of hanging views, is the power of placing it at any angle to the light. Especially is the value seen in plain or shaded backgrounds. A sitter is posed; the harmony is complete between the light he receives and that thrown behind. A blind or two is altered to improve the illumination of the features, at once the background becomes too dark or too light. If, however, a framework on castors is in use, all that is necessary to restore the original harmony of *chiaroscuro* is to place it at an angle to the light, move it to face the light a little more, or turn it away from the light, and at once increased lightness or darkness of effect is obtained. It would appear that a theoretically perfect way of lighting the ground would be to have a special walled illuminating slit which would permit its light to fall on the ground and nowhere else, then the exact effect required would be produced; whatever the mode adopted for illuminating the sitter, no shadows would be thrown on the clouds, and complete harmony would result.

Photographic Evidence.—We are informed that a case will shortly be before the Law Courts in which photography, as a witness, will be in evidence on a much larger scale than on any previous occasion.

Royal Portraits.—Some little excitement has been created on the Continent by the sudden disappearance from his home for several days of a young German prince. In England every one is now so familiar with the portraits of the members of our Royal Family, that one is inclined to wonder how any member of a foreign one would not be at once recognised wherever he went—at least, in his own country. On the Continent, particularly in Germany, we are informed, photographs of royal personages are not so common as they are here. Evidently sittings from them are not so easily obtained, or photographers are not so enterprising as they are in this country. There may yet be another reason—royal portraits are not in such great demand abroad as they are in England.

National Photographic Gallery.—The First Commissioner of Works has announced that the Milbank Prison is forthwith to be demolished, and a portion of the space offered for the picture gallery Mr. Tate has so generously offered to build. This offer, it is stated, has been accepted. The announcement has also been made that another portion of the site will be exchanged with the War Office for some land belonging to them behind the National Gallery for the still further extension of that building. Hence a considerably increased space will soon be available for pictures. The present would be an opportune time to bring before the proper authorities the subject we have before mooted, namely, a national collection of photographs—for example, portraits of men, who have distinguished themselves in art, science, literature, or in other connexions during the present age. The collection need not be confined to portraits, as it might well include photographs of ancient buildings in London and other large cities which are continually being demolished to make way for modern improvements. A collection of these and of buildings that have been removed during the last few decades—if negatives are in existence—would not only be of interest to the archæologist of the future but also the present period. If the Photographic Society of Great Britain, in conjunction with other scientific and learned societies, were to take the matter in hand, the thing could now, doubtless, be accomplished. Of the desirability of such a gallery there can be little question.

Carbon Printing.—A considerable proportion of amateurs who have not seen the process worked imagine that a large number of appliances, not found in the den of the ordinary amateur, are necessary for its practice. This idea, in great measure, has been formed from the manuals of the process, in which a long list of articles, with prices of "sets," are given. Very possibly this has had the effect of retarding the progress of carbon printing amongst amateurs. As a matter of fact, the carbon can be worked with less special apparatus than any other process in photography. This subject was particularly dwelt upon at a recent demonstration before one of the suburban societies. We remember being at a demonstration of the carbon process at the Photographic Club some time ago, when the only appliances, beyond the exposed tissue and its final support, were a squeegee and a wash-hand basin borrowed from a neighbouring bedroom. Mr. Cowan and warm water did the rest. All that is necessary in the initial stages for the amateur is a large meat dish, to be requisitioned from the scullery, and a tin or enamelled iron baking dish from the same source: the former for holding the water for mounting the exposed tissue on its support, and for the sensitising bath, if the sensitising be done by the experimentalist, and for the alum bath; the latter for the warm water for developing. In addition to these, a squeegee is required, and, for the beginner, a thermometer is desirable. As extreme accuracy—a degree or two—is not essential, one of the cheapest form will suffice. One more item is necessary, namely, an actinometer. The one preferred by Lambert for his demonstrations consisted of a series of progressive thicknesses of thin bank post paper in a quarter-plate pressure frame, with a piece of sensitive silver paper behind, which any one can make for himself in a few minutes. Hence it will be seen that the most primitive arrangements will suffice to prove the process. That being done, the amateur can then elaborate them to suit his requirements. The progress of processes is often retarded by their exploiters introducing a number of accessories which they supply, and some think necessary, for the work.

A VISIT TO A FAMOUS AMATEUR—HOW MR. HENRY STEVENS WORKS.

In photography, as in other departments of art or applied science, it is the one who devotes himself to one branch who has the highest

chances of success in making for himself a name and fame in a specialistic branch. This is what Mr. H. Stevens has done in the by no means easy one of floral photography. But for his photographs of flowers we would say that he is a good all-round artist in nearly every department. Without claiming to be a landscapist or group photographer, yet have some of these with figure subjects been selected for full-page engravings for the leading illustrated papers; and, while he largely ignores the distinction of being considered a portraitist, yet do many of his portraits possess a very high degree of merit, both in a pictorial and technical sense.

But, as we have hinted, it is in the portrayal of flowers that he is universally acknowledged to stand *facile princeps*. There are some of Flora's treasures much more easy to photograph effectively than others, but those who have in recent exhibitions been privileged to examine Mr. Stevens' productions will at once acquiesce in our statement, that he flies at only the highest game—at things avowedly the most difficult of execution. A white lily, in the hands of most photographers, would have its petals represented in flat chalkiness, without detail; but in those now under notice, while, like the original, pure and white as a whole, there is a waxy, transparent delicacy which reveals the veins and structure of every part of the flower, even to the extent of permitting such structural detail to be examined by a powerful magnifier. As with lilies, so with orchids, even those of the most fantastic shapes and colours, for in these Nature seems to excel herself in regard to both qualities. A singular property is that while photographing these flowers life size or nearly so, and reproducing their tints with such delicacy, Mr. Stevens has not yet made use of colour-corrected plates, but trusts exclusively to obtaining his effects by lighting, supplemented, of course, by correct exposure and judgmatical development.

The studio, which measures probably about eighteen by nine feet, and stands in the garden, has a ridge roof, one of the sides and half of the roof being closely screened—at least it was so at the time of our visit. The huge camera employed occupies much of the floor space. The lens is a large aud somewhat old portrait combination of long focus, and has a stop in front of the anterior combination, although he possesses a large collection of lenses of modern construction. The exposure is made by a pneumatic shutter.

It is in the lighting where the long experience of the artist shows to advantage. His subjects are placed on a table on a raised platform at one end, and, the side lighting having been arranged, there is a further modification of the lighting by the use of an opaque movable screen, which rests upon the eaves and the ridge. The developer preferred for the special brand of plates employed is pyro and soda, and he considers it wise to carry the development considerably farther than would others of less experience. We may adduce as an instance of one of the lovely transparencies which adorn one of the windows of the Camera Club, and which was printed from a negative so dense as to require an exposure of thirty minutes to a good daylight sky, not by superposition, of course, but in a transparency copying camera.

In course of our visit we saw several hundreds of negatives and transparencies—for Mr. Stevens is an indefatigable worker—including those in the late Exhibition in Pall Mall, for which a medal was awarded, and came to the conclusion that the large majority of them possessed merit not inferior to those which excited such admiration in the Exhibition just mentioned.

The developing room is a separate building from the studio, and is erected at some little distance from it. It is of larger extent than the studio, for Mr. Stevens likes to have plenty of room in which to work. This is indeed necessary, for, as we have said, the plates used by him are of large dimensions, and he prefers a very feeble light. He holds the plate in an ebonite dish in his hands during development, and usually rocks it on the edge of a trough just below the gas lantern, which is well covered by paper of a canary medium species. Plenty of time is given so as to coax out every detail. In the course of the development the fluid is poured once or twice, as occasion requires, into a large graduate, to which is then added soda, pyro, or bromide so as to modify its action when returned to the plate.

Outside of the developing room is ranged a row of several washing tanks, with water taps just above each, and all this portion is covered in by a glass roof. A workshop adjoining is also to some considerable extent impressed into the service of photography; but perhaps the most interesting department is an observatory, originally constructed for sidereal observation, and having a rotating dome as a roof. This has now been relegated to enlarging. The telescope has been deposed, and its place given to a camera, which can be directed to any part of the sky. The idea of being enabled to enlarge a large negative by an apparatus which is practically equatorial is calculated to fill one with envy.

It is, however, in the billiard room where the rich store of negatives, prints, and transparencies are hoarded. The billiard table has a strong and readily removable wooden cover, on which the sorting, mounting, and framing are done. How a gentleman so actively engaged in his business avocations in London, as Mr. Stevens is so well known to be, gets through his amateur photographic work unaided (for he does everything with his own hands, and without any assistant) is truly surprising. It can only be accounted for by his being quite an enthusiast, and straining after perfection—the unattainable.

In this connexion we may record an incident. Having gone to Eastbourne with his family for a few weeks' holiday in the summer, he was one night struck with an idea relative to the obtaining a new effect in lighting. Early next morning he took train back to London —or, rather, to Addlestone, his place of residence—and immediately proceeded to test the value of his idea before returning to the seaside. We consider that much of his success is due to this dogged perseverance in straining after perfection, added, of course, to a naturally fine taste and good manipulation.

His large portrait work is marked by softness, not so much obtained by placing the sitter out of focus as by modifying his lighting. We cannot say with precision how large are the heads of such direct portraits, but we may state that, roughly speaking, the faces of several portraits of some young ladies we saw could barely be covered by the partially closed hand of a strongly built man. Neither in his flowers nor in his portraits does he permit of the smallest touch upon the negative to improve it; if it does not come out all right with the developer, it is destroyed without hesitation.

Two conservatories, well stocked with flowers and plants, furnish floral subjects for his camera, while in another part of his grounds stands a closed photographic waggon, replete with everything necessary for storing, changing, and even developing negatives on such occasions in prospect of obtaining skating scenes on lakes at a distance from home, for harvesting, picking up a gipsy encampment, or other scenes not obtainable at home. To secure these, his horse is harnessed, and off he goes to bag the game.

Before terminating our visit, we made the acquaintance of his famous photographic dog and cat, which have figured in many of his pictures. The former, a fox terrier, is trained to throw his arms around his Persian *confrère*, who quietly submits to the caress of the canine until as many exposures as are required have been made.

AMERICAN NOTES AND NEWS.

The Hand Camera and its Abuse.—In a sensible article dealing with the tendency of modern amateurs to produce inferior results by means of the hand camera *Anthony's Bulletin* remarks: "There can be no doubt that the number of users of the hand camera is increasing at an enormous rate. The portability, compactness, and general simplicity of action of the instrument commend it to all. But, of all photographic instruments, it is the one calling for the exercise of judicious self-restraint and careful handling. The user must remember that an instantaneous picture is usually an underexposed one, and that it is practically useless to attempt to photograph a poorly lighted object unless an exposure of one half to one second can be given. The users of tripod cameras seldom expose with the shutter unless forced to do so, and the percentage of results ranks considerably higher than that of those of the hand camera. The users of the latter instrument rarely, indeed, use the time attachments, and therefore must depend on the extreme rapidity of their plates or films, and on the choosing of well-lighted subjects. In most of the cheaper hand cameras the lenses are perforce diaphragmed down so as to give good depth of focus, for the focussing is done chiefly by a graduated scale. The lens will work usually about right

if the light is really good. Under any other circumstances the negative will be poor and weak.

English versus American Cut Films.—Dr. Charles L. Mitchell contributes to the *American Amateur Photographer* an account of his recent photographic experiences in this country, in the course of which he says: "My photographic material consisted of cut celluloid films for the two larger cameras, and glass plates for the hand camera. The films were from a manufacturer whose products had served me fairly well in the trips of the two preceding years. . . . Alas, however, the films were soon found to be exceedingly bad, especially the quick emulsion, but not before much valuable work had been lost. They were scratched, spotty, and full of pinholes, and seemed to lose their image unless developed immediately after exposure. A change was therefore made to English films." Dr. Mitchell soon became convinced, from the change, of the advantages of English over American films, which he attributes to superior skill and care in coating.

"Wilson's Magazine."—Our contemporary will in future appear as a monthly, thus reverting to its former course. Considerable alterations and improvements are promised.

Is the Top Light Essential in Portrait Work?—Mr. J. A. Todd, of San Francisco, raises this question in a communication to *Wilson's Magazine*, and asks that, if a top light can be dispensed with and a side light alone take its place, would not photographers be enabled to occupy a cosy, conveniently accessible ground-floor suite of rooms, put in a large side light in one of the end rooms, and do more business in consequence of the more convenient location?

Photographic Printing by Moonlight.—Dr. John Vansant, of Mobile, Alabama, describes in the *St. Louis and Canadian Photographer* some experiments proving that the light of the moon is capable in a short time of producing a developable impression upon a sensitive silver bromide film. The exposures on commercial films of varying degrees of rapidity ranged from three minutes down to five seconds. The latter exposure to the rays of the full unclouded moon when near the meridian being sufficient to produce a good developable impression upon an uncovered extremely sensitive film, it appeared that the same kind of film when exposed beneath a weak negative required a minute's exposure, Dr. Vansant thus calculating that about ninety-two per cent. of the actinic rays of the moon were intercepted by the glass and gelatine.

Arctic Photography.—*Apropos* of our recent remarks concerning Dr. Nansen's intention of taking a camera with him on his Polar journey, it is interesting to learn that Lieutenant Peary, the Arctic explorer, who with his wife has just returned from the north, had a Kodak with him on his journeyings. Eighty-two degrees was the most northern point reached by Lieutenant and Mrs. Pearey, and is said to mark the farthest limit to which the camera has as yet penetrated. Lieutenant Pearey made over 1300 exposures. The films were developed by a Philadelphian photographer. The Secretary of the American Navy, it is stated, has granted Lieutenant Pearey a further leave of absence to make a second attempt to reach the North Pole.

"Improvement in Photo-zincography."—For transferring photo-litho copies to zinc plates Herr August Albert details, in the *Photographic Times*, the following method:—The copy is printed, developed with fatty ink, and dried as usual. The drawing is afterwards dusted in with a finely pulverised mixture of ten parts of asphaltum and one part of pure beeswax, and all superfluous asphaltum removed by means of a fine camel's-hair brush and a tuft of cotton, and slightly heated over an alcohol lamp to melt the asphaltum together with the fatty ink. The copy is then passed through the saturated alum bath to keep it uniformly moist, laid between sheets of moistened blotting-paper, and finally transferred upon a zinc plate.

FLASH-LIGHT PHOTOGRAPHY.

[Toronto Camera Club.]

THE making of pictures by the aid of the magnesium flash-light has been undergoing a process of evolution for the past five or six years. The journals have contained many papers upon the subject; chapters discussing it are to be found in a large number of manuals; and at least two books dealing entirely with it have already been published. It is no part of my present purpose to sift this extensive literature for you. Instead, I shall content myself with demonstrating certain methods which, having tested, I have found to be at once simple and satisfactory. For the needs of a surgeon these procedures are particularly well suited, and it is to one of my own craft, Dr. Piffard, of New York, that we are all indebted for the introduction here of photography by artificial illumination. In this connexion it is worthy of remark that, for the production of the most accurate and life-like pictures of skin diseases and other morbid conditions, Dr. Piffard prefers artificial to sunlight. He has recently brought out a work illustrated by such photography, and surpassing in many particulars, any previous publication on the subject.

It is within my knowledge that many amateurs who do creditable work out of doors have with magnesium failed to obtain any results which they cared to exhibit to their friends. Deep shadows, hard, chalky high lights, staring eyeballs, burns, dirt, and disappointment have been their reward, instead of the artistic results they had hoped for.

At the risk of going over what is perfectly well known to many, if not most, of those present, let me mention some of the essentials for success in this line of work. The lens, preferably one of the rapid rectilinear type, must not be stopped down below *f*-11; the plates used must be fast ones, such as the Cramer "C" or the Seed 26x; the background must not be too near the sitter or it will show direct shadows, and its tint should be lighter than for use with daylight. The correct focus is most easily and rapidly obtained by the use of a lamp, a newspaper, and a focussing glass. Let the light of the lamp fall upon the newspaper, held upside down, and raised, lowered, or carried out to the sides, in order to determine just what will and what will not come upon the plate. As a general rule, the gas or lamp lights should be turned up, so long as they do not shine into the lens, and they should light up that side of the face which will not be lighted by the flash. In this way its shadows are softened, and hard lines avoided. It is a good plan to have the sitter look directly at one of the gas jets or lamps. He will thus not be so much disturbed by the sudden increase of light when the flash is made, and will not be so apt to have a startled or staring look, or to close his eyes suddenly.

I think the advice often given to place the flash apparatus over the camera, is an error. It is better to have it placed higher than the lens, and to one side or the other of it. An exception to this is seen where a fireside or camp-fire group is to be taken, and the object is to make it appear as though their faces were lighted up only by the fire around which they are placed. Even in photographing a cavity like the back part of the throat, I have found the detail brought out best when the light came from a position slightly to one side of the lens. For diffusing the light, and so obtaining soft instead of hard negatives, a sheet of ground glass is excellent, and a sheet of bright tin makes as good a reflector as need be desired. I have used for more than two years a convenient arrangement, consisting of a piece of board fifteen to twenty inches long by one foot wide, with a plate fixed to the middle of its under surface, so that it may be secured upon any tripod stand. At each end of its upper surface a pair of parallel wooden strips are nailed so as to form slots to support, in upright positions, the tin reflector and the ground-glass diffuser. Between these two the flash-lamp is placed.

After trying a number of the patented articles, I have reached the conclusion that the simple one which I devised, and described in the *Beacon*, gives as good results as any other, and has the advantage of being easily made by any one with skill enough to press a button. A flower-pot saucer has a hole bored through its rim to allow of the passage of the stem of a clay tobacco pipe. The bowl of the pipe is to be fixed upright in the middle of the saucer by means of plaster of Paris. A rubber tube, ending on a mouthpiece, is fitted over the stem of the pipe. Next a wire ring, supported at a height of three or four inches, is placed so as to surround the pipe bowl, and upon this ring asbestos wicking is twisted.

When it is desired to make a flash, from five to twenty grains of pure magnesium powder is to be placed in the bowl, and the wicking is to be saturated with alcohol. Lighting the alcohol, and then blowing through the tube, forces the powder into the long axis of the flame, and perfect combustion takes place. By a number of experiments, I have demonstrated that a sudden strong blast which lifts the

powder in a mass out of the pipe does not give as good result as a gentle one promptly followed by a forcible blowing. This latter method loosens up the powder, and then sends it through the flame in balloon form, giving a maximum of illumination with a minimum of magnesium oxide, falling as a dust cloud after the flash has been made. Asbestos is much better than candle-wick, as it does not burn, gives off no smell, and the flame on it can be easily blown out.

In some particulars the diffusing apparatus above described resembles a patented article sold in the United States; but mine was in use before that came out, and the cost of the entire outfit need not exceed a dollar. Any one can make it, it comes apart for packing, and the results obtained by its use in the hands of my friends, as well as in my own, are not discouraging. DR. N. A. POWELL.

DIPPING-BATH DEVELOPMENT.

[Photographische Rundschau.]

DIPPING-BATH development (*Standentwicklung*), has been in use for three years at the establishment conducted by the writer, where large numbers of negatives have to be produced after methods certain to give good results, for "interiors," having had an exposure of as much as four hours, as well as for plates having had only four seconds, such as "exterior architectural subjects."

The principle of dipping-bath development is found in the prolonged action of a very diluted developer contained in a dipping-bath, which, being provided with grooves, admits the simultaneous treatment of several plates.

The advantages of employing pyrogallic acid for this kind of development are so numerous that all trials with more modern developing agents were abandoned, they not permitting such a high state of dilution and such a certainty of success at such a small cost.

Negatives produced by this method show a very fine grain and a range of gradation, even in the highest lights, which no other method ever will give, making them especially suitable for enlarging on bromide of silver paper.

For ordinary work the formula is as follows:—

1 : 10 solution of soda sulphite	100	parts.
1 : 5 solution of potassium carbonate	100	,,
Water	10,000	,,
Dry pyrogallic acid	2	,,

For instantaneous work—

1 : 10 solution of soda sulphite	100	parts.
1 : 5 solution of potassium carbonate	100	,,
Water	3,000	,,
Dry pyrogallic acid	1½	,,

In this state of dilution pyro also loses its most obnoxious property—staining the fingers and plates—entirely, and gives negatives of a harmony beautiful to behold.

To obtain the very best results, thickly coated plates of a medium rapidity and with no tendency to frill should be employed.

DR. A. MEYDENBAUER.

THE ARBITERS OF HONOUR.

APART from those inevitable exceptions, whose apparent office is to accentuate a truth by demonstrating the small number of dissentients thereto, "the world thinks, and I think so too," that the most precious signet of success is the medal bestowed at what is still, and still likely to be, the most keenly inspected annual Exhibition of the year, viz., that held under the auspices of the Photographic Society of Great Britain, for which reason I doubt not that all who have the present welfare and future advancement of photography at heart will bear with me while, supplementing my former article on p. 741, entitled, "The Plague of Medals," I offer some suggestions specially directed to ensuring that there shall be no depreciation in the value of the aforesaid premium, but that, as time goes by, it may become even more highly valued than at present.

I do not claim that the following proposals are alike perfectly novel and completely perfect, these two qualities being usually incompatible; but I do claim to have given the subject considerable thought, and to have brought to its examination a mind open to consider any alteration calculated to raise the status of the Pall Mall medal.

The first reform which in my estimation seems advisable is the adoption of a far more *rigid* system of recognising and remarking that which is *in excelsis* meritorious on the Exhibition walls. This of necessity implies some modification in the constitution of *the arbiters of honour*. I will, therefore, shortly, state what in my judgment are the lines upon which the bench of Judges should be constituted, leaving it to those in authority to apply that which, being lacking, they nevertheless approve.

The three following points should characterise the Judging Committee:

(1) It should be widely representative and distinctly capable.
(2) It should not include a majority believed to represent any known "community of interest."
(3) It shall include one or more individuals (as may be in due course defined) who are definitely representative of
  (*a*) Artistic culture.
  (*b*) Photographic craft.
  (*c*) Optical, chemical, and general science.
  (*d*) Provincialism.

Respecting the above, little comment is called for, except perhaps as regards section 3, concerning which, it is to be observed, that while the Judges described under *b* and *c* are most unlikely to be unconsciously (or otherwise) partial, having, as hereafter provided, only to deal with points of excellence which are essentially unemotional in their appeals to the critical faculty, the same can by no means be said of those coming under either category *a* or *d*, where the personal element is apt to be decidedly intrusive, and *nolens volens* influence the Judges' decision. For this reason I would advocate that those chosen as representatives of "provincialism," *d*, should be selected from amongst men of *recent* standing, rising men; of such the big, and many of the little, towns collectively contain many a score. As for the representatives of "artistic culture," although no man can be hoped for who does not prefer one form of expression rather than any other, yet a judicious admixture of individuals of different artistic inclinations is not impossible, in any case one or more painter-artists should be included who is neither a member of the society nor known as a photographic practitioner.

From the foregoing it will be readily inferred that the present manner of appointing Judges, which is by a species of general election on the part of members, must be revised. At any time, ruling by quantity instead of by quality is obviously bad; that it is ever resorted to at all is in order that the interests of the multitude may be safeguarded. But of a certitude the intrusion of the vote by ballot into the administration of a society formed for the stimulation of applied science and art is largely anomalous and emphatically undesirable. Even political governments of advanced radical types do not provide a means whereby the electorate regularly meddles with executive functions.

The delicate and complex task of wisely blending the jury of experts should, without doubt, be undertaken by those who are in authority, and should be the outcome of leisurely deliberation and nice discrimination, strictly applied upon such lines as may be laid down. That this be properly and carefully done by the Council, the President for the time being should be held personally responsible, and upon him should rest the ultimate blame if any one manifestly unsuitable be appointed.

And now I come to a detail which may possibly arouse some difference of opinion, but which I think should not, on that account, be passed over. I have gradually formed an opinion that, in the case of a society such as the one we are considering, it should be a *sine quâ non* that on this appointment all Judges shall, as a matter of course, be handed a fixed honorarium for services to be rendered—a kind of retaining fee—in exchange for which they should sign a printed form of acknowledgment, undertaking to attend at the time fixed, and carry out, in accordance with the instructions furnished to them, the duties thereby cast upon them.

It is beyond question that men of sterling worth find few things so valuable to them as their time. Now, although I do not in the first instance advocate any remuneration which is likely to be an equivalent for the hours and energies taken from a busy career (and even amateur photographers have business occupations of one kind or another), I do think that some recompense should be made which will, in the majority of cases at least, ensure that the out-of-pocket and personal expenses of the adjudicators are fully covered.

That penury waits on pre-eminent ability is too notorious to need enlarging upon, and the lack of a few paltry shillings may ofttimes prevent a gifted individual from placing his natural or acquired abilities at the society's disposal. With a powerful and ambitious organization such as is the one in question, the maxim should be, *Do ut des*, and not, "Take all and give nothing," which is nearly all that the Judges get, except, sometimes, the dubious honour of being eventually held up to ridicule for the way in which they have done their work.

Having delivered myself of my suggestions upon getting the right sort of Judges, I should like to add my ideas as to how they are best set to work; circumstances of time and space, however, oblige me to

defer doing so until a future occasion, when I trust to bring forward some proposals on this most vital point which, I venture to hope, may in part, if not altogether, commend themselves to the serious attention of those whom I will term the progressive conservatives of the parent society.

HECTOR MACLEAN, F.G.S.

RECENT SCIENCE AND PHOTOGRAPHY.

(Abstract of the Presidential Address before the Photographic Society of Great Britain.)

WHEN a truly wonderful thing becomes common it ceases to attract interest except to the few. Thus one marvel in science is the action of light on sensitive surfaces. The keen interest which all can take in the development of a plate is nothing to the keener interest which the mind should feel in trying to trace the reason of the phenomenon. Some few years ago we had to familiarise ourselves mentally with atoms and molecules oscillating in an incompressible ether, and in this case "faith was a precious grace," for it was hard to conceive it possible; and now we have to slightly alter our mental picture and conceive that the ether of space is compressible; for comparatively recent considerations have shown that the original mathematical investigations of the motion in the ether which we put as light and which explain all the phenomena met with, no longer require us to consider incompressibility as a necessity. This has freed the way for us to cogitate over possibilities, and to amend our theories of the formation of a photographic image—or rather, perhaps, I should say to prevent them being seriously objected to owing to the non-inclusion of what used to be considered a necessity. So far then mathematical science is opening instead of barring the way for a truer conception of what takes place. Chemistry, too, I need scarcely say, is also helping us forward in the work of molecular physics. Those web-like graphic formulæ which we see pictured in chemical journals have more meaning than at first sight appears; and they would have even still greater meaning if, instead of chains of affinities represented on a plane surface they were represented in space of three dimensions.

The law of, what for simplicity I will call molecular attraction, has been expressed mathematically, and puts before us the possibility of telling what is limit of space in producing photographic action, and I would point out that up to the present time it has been held that if time and intensity of light give a certain chemical change in a body, then the same will be produced if the two multiplied together give the same constant. I think that we must put this law on the same basis as that of gravity, which is that bodies attract one another inversely as the square of the distance between them until we come into distances between the bodies which are to be compared with the diameters of the molecules, when another law must be applied. In the same way when we get intensities of light which are almost infinitely feebler than those with which we are accustomed to deal, the "time-into-intensity" law will be found to break down. This follows almost from physico-mathematical considerations. Quite recently, too, we have had a chemist investigating the action of light on chloride of silver in a more perfect way than has hitherto been attempted; and, if I read aright, we come to the conclusion that the same conditions are necessary in it that are necessary to produce electrical action. Following up in these lines we may get to know more certainly the chemical action which takes place in a photographic plate than we do at present. There has often been one objection made to any chemical theory of photographic action which I have often had to combat, and I can but repeat my argument against the objection, as I conceive that if removed it is one of the stumbling-blocks which prevents progress.

The objection is this: that such a large part of the spectrum is active on a photographic plate. Our conceptions of photographic action are that the wave of light shall beat time with the oscillation of the atom in the molecule of the sensitive salt, and increase the swing of the atom, eventually causing it to quit its parent molecule and join itself to some adjacent one. If this be the case, it has been argued that the salt of silver should only be sensitive to one ray of light, since that oscillation of only one set of waves should be able to effect it. Here mechanics help us. A pendulum will be increased in swing even though the intervals of time of the outside impulses given to it do not exactly coincide with the time of oscillation of the pendulum. The swing of the pendulum will be increased by every set of impulses to a certain degree, and will then diminish the swing, bring the pendulum to rest, and start it once more on its travels. That is to say, at one period the amplitude will be increased by once its ordinary swing. So with the atom in the molecule, any series of waves which will increase the distance of the atom from the centre of attraction, even by the smallest quantity, may increase it so much that the attraction to that centre is less than to another, and the atom may thus swing off, and the stoppage of the swing by the further ill-timed vibrations of the ether will be effective. If we took the doctrine of averages, which is so useful in molecular physics, this could not be the case, since the average amplitude of the atom would approach to that of the normal swing, except where the wave motion and the atom motion were in actual harmony. The same reasoning applies to the absorption by the sensitive salt, which, if it alone could be effected by a ray of a single colour or wave length, would only show that absorption. I may remark that the same line of argument applies to the three-colour sensations in the eye. That the latter are due to the same cause may be shown by comparing the curves of sensitiveness of a sensitive salt and those of the colour sensations. They will be found to be essentially the same in character and general shape.

There can be but little doubt that the sensations of colour are as truly photographic as the effect on a sensitive plate, and I would here remind you that a photographic action is as truly present when the exposure given is short as when so prolonged as to become visible. A photograph on the retina may be invisible if it be examined for any change; but the chemical action may be equally well transmitted to sensatory nerves. Colour fatigue is probably due to a printing-out action, whilst a negative image in the eye, after fatigue, may be attributed to the same causes which give a reversal to the photographic image on a plate. The difference between a sensitive plate and the sensitive retina may alone consist in the fact that in the one the receiving sensitive compound is a motionless solid, in the other that it is a moving liquid, constantly changing and being renewed. In establishing any theory, due regard must be paid to temperature. Heating a body means increasing the motion of the component molecules, whilst chemical action means increasing the motion of the atoms. The molecule will not necessarily suffer any change by heat except that of increased motion, and will revert to its original state when the heat is withdrawn, whilst the atom's motion may so increase as to cause a chemical change, which is likely to be a permanent change of state. When the molecules are further apart it is evident that the atoms have most scope for movement, whilst when the molecules are very close together their motion must be decreased. The last is exemplified in extreme cold, and Professor Dewar has shown that even at the temperature of liquid oxygen (−200° C.), bromide of silver is sensitive to light. From this fact he has concluded that the change in the salt is more physical than chemical. For my part, I do not see it in that sense, and the sensitiveness of the salt at normal temperature and at this extreme cold will have to be measured before any real conclusion can be drawn.

Little by little science is enlightening us as to the dimensions and distance apart of molecules, experiments are explained by mathematical investigation, and, in almost shapeless outlines of ideas, details are gradually being filled in, and the picture to the mind begins to assume beauties in design which at first could not be dreamt of. Photography is essentially a branch of molecular physics, and thus we are gradually able to approach a knowledge which is not altogether vague. Ideas get simplified as the mind gets enlarged, and analogues in nature help us in thinking out our theories. A theory conceived and proved, after all, is but removing a cause a step further back; it is leaving another milestone on the way behind us. How many more there are to pass we know not. Theories are but the silken threads which may guide us through a labyrinth, and when we extract ourselves from it we find the maze we have left but the entry into another. Yet this need not cause disappointment or despair. Each difficulty conquered leads us nearer to the prime cause, and let us remember that the infinite is only reached by the finite, and it is but a few months ago that Lord Kelvin, who has long been a peer in science, demonstrated a fallacy in a mathematical law.

CAPTAIN W. DE W. ABNEY, F.R.S., C.B.

EXHIBITIONS AND JUDGES.

THE paragraph in the JOURNAL *re* the Judges' awards at Tunbridge Wells is well timed, and likely to revive the perennial discussion on the matter of judging and exhibitions generally. It is a pity we cannot once and for all settle this vexed question by the establishment of a central controlling body, formulate a set of rules which would meet the views of the majority of exhibitors, and put a stop to such fiascos as that at the town named.

Looking at the mighty strides made by photography during the last ten years—advances not merely commercial but artistic—we must give the lion's share of the credit for this result to the numerous exhibitions which have been held. Some of the competitions have been open to much criticism, but on the whole the rivalry has been

healthy and devoid of bitterness. Much comment has been made re the superfluity of awards in certain quarters, but this error—which is rendered of less direful effect by the ridicule of the Press—is small in comparison with the effect likely to result from action such as that of the Judges at Tunbridge Wells. It will be a thousand pities if such action be allowed to curtail in any way either the number of exhibitions or exhibitors. Every one connected with photography (with the sole exception of the unfortunate Secretary) benefits by these exhibitions, and personally I think it would be better to let the silver and bronze tokens be scattered abroad even more liberally than hitherto than to lessen by one print (and this is a large order) the numbers at our exhibitions.

The award, after all, of medals and applause does little harm; it is kindly intended, it is often a great incentive, and has but one occasional and regrettable effect, when, given not wisely but too well, it induces the recipient to imagine henceforth that photography is his Heaven-sent gift, and, in short, impels him to join the ranks of an already overcrowded profession—a profession, by the way, for which he is, as a rule, by no means well fitted. This is the one ill effect, I think, of indiscriminate awards, but, so far as it concerns the Judges, the fault is but a pleasant one. In the selection of Judges, the committees appear to all adopt one course—they glance through a list of names, gentlemen of good repute, all of them; the majority have received scores of medals for a certain class of work, others have identified themselves with various fads, and become apostles and high priests of sundry accidental creeds, all of which unfits them for judicial functions. Sometimes, indeed, we shall find, but *rarely*, the man with this accumulation of awards becomingly modest—doubtful of himself. At times he may say, "Yes, I've been rather lucky; they seem to like my work, though I'm not *quite* satisfied with it myself." But as a rule he doesn't; he is quite prepared to uphold his own work as the alpha and omega of all photography, and to sit upon all comers. The faddist, of course, because he *is* a faddist, should never be chosen; such men can see no beauty—nothing to applaud beyond their own narrow circle.

I have a plan to propose which would necessitate some concerted action on the part of societies; but, as some of the latter are affiliated to the Photographic Society of Great Britain, this preliminary would be overcome. It is, for the societies to select and appoint a Judge; this gentleman to be a photographer of known ability, conversant with all recognised processes, of liberal, not to say broad, mind, as regards opinions; one who, admiring the man of "studies," could still appreciate pure landscape or a bit of architecture; who could sympathise with, and encourage the aspiring locals, and generally give an unbiassed opinion. Such a man could be met with, undoubtedly. He should be paid a fee over and above expenses, and would be expected to provide a report to be published and issued to the competitors, setting out his opinions of the pictures shown, giving praise and blame in due proportion, pointing out the beauties of certain work, and the defects in others. This, in many local exhibitions, would be invaluable. Such a Judge, being *au courant* with most of the work already shown, would be able to spot at once the over-exhibited work, and might be relied on not to be "bluffed." *Criticism* is what exhibitors appreciate; not to be told in as many words that "we have fixed a very high standard of excellence, and anything short of this will not be considered."

The Society to which I had for some years the pleasure and honour of acting as Secretary used to have, and, I think, does so still, occasional shows confined to members' work. I would advocate annual functions of this kind. Initiate the younger members into the mysteries of exhibition work amongst themselves, and then, in course of time, they are better prepared to compete in the open classes. They come to see gradually that a standard of excellence is necessary to deserve a place on the walls, and the rest is then better understood.

I doubt whether "presentation prints" are popularised so much as they might be. A capital method of educating our younger members and others who have seldom the opportunity of visiting the chief exhibitions would be for the Central Controlling Body to make a collection of such good examples of photography as they could get the permission of the owners to utilise, have them reproduced in collotype or some such process, supplying them to the Societies at a reasonable rate for distribution to the members. I remember the Society to which I have referred in one year paid for a presentation print—one print, by the way—a sum of about two shillings. I believe it was about that sum. It must be obvious that the combined members of some one hundred and fifty societies could receive a very handsome collection of views for that amount each. The educational value would undoubtedly be enormous.

But all this means concerted action, and that is a state of things likely to be reached, if it ever is reached, very slowly. So far as I can see the Photographic Society of Great Britain is the only body at present in the condition, on account of years and standing, to take fully into consideration the question.

J. PIKE.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

14. *Distortion. Deflection or sag in the image of a straight line which, if there were no distortion, would run from corner to corner along the longest side of a ——— by ———plate = 0· ——— inch.*

The following is the method adopted at Kew of measuring the distortion produced in the image by the lens under examination. Let fig. 14 be a vertical section through the testing camera; GG representing the ground glass; F the principal focus; and N_1 the horizontal axis, which passes through the nodal point of emergence, the adjustment for that purpose having already been made for test No. 10. The lens-holder carrying the lens is first turned in either direction through an angle β, such that PF, or FN_1 tan. β, or f tan. β is equal to half the *shortest* side of the plate for which the lens is being tested. (The *horizontal* movement of the swinging beam in the testing camera gives an easy means of determining the angle β; a distant object is first brought to focus at the centre of the ground glass, and then the swinging beam is revolved about

FIG. 14.

the axis A (see fig. No. 1) until the image has moved along the graduated scale a distance equal to half the shortest side of the plate; the beam is thus made to move through the angle β, which can be read off with sufficient accuracy on BC, the top of the wooden stool, which is graduated for that purpose). After this adjustment has been made, the ground glass is brought into focus by observing the image of a distant object at a point P, a little below C, the line engraved on the glass; under these circumstances, if the principal focal surface is a plane, and if the lens were being used in the ordinary manner, PP' would be the position occupied by the photographic plate, the section shown being taken across the centre of the plate parallel to its shortest side. The small distance PC is carefully measured; this length is then multiplied by secant β, thus obtaining C'P, which we will call a. The swinging beam is now revolved about the pivot in either direction, so that the image moves along the scale on the ground glass a distance equal to half the *longest* side of the plate for which the lens is being examined; the sketch in fig. 7 is still more or less applicable, PP' still representing a section across where the photographic plate ought to be, but this time at the end of the plate, not at its centre (F, therefore, no longer represents the principal focus); in fact, what has been done is to make the image describe what, neglecting distortion, would be a straight line from the centre to the corner along the longest edge of the plate: after this movement has been made, the length of C'P is again obtained by

* Continued from page 776.

measurement and calculation, and this time let the result be called *b* the operation is repeated when the swinging beam is revolved to an equal angle on the other side of zero, and a third length, *c*, is thus obtained. In fig. 15, let BAC be equal in length to the longest side of the plate, and let *a*, *b*, and c be the lengths just obtained; then the curve *bac* will evidently represent the image of a straight line thrown by the

Fig. 15.

lens under examination along the edge of the longest side of the plate. Since the image travels along a line very nearly parallel to the engraved line on the ground glass, BAC will be nearly parallel to the chord of the curve, and $\frac{b+c}{2} - a$, which is the length recorded in the Kew certificate, will be a very close approximation to the sagitta or sag of the curve.

The image of a rectangle near the limits of a photographic plate will appear, when any distortion is visible, like one or other of the forms indicated in fig. 16. The sagitta is conventionally considered positive if it is measured towards the centre of the plate from the chord, thus giving the name of positive and negative distortion in the two cases.

The distortion for distant objects is not necessarily exactly the same as for nearer ones, and therefore the uses for which the lens is intended should not be forgotten; for example, with portrait lenses an object some

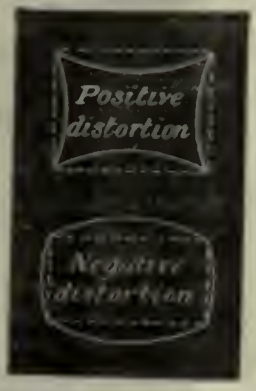

Fig. 16.

ten to twenty feet away should be used to throw the image in the above test.

Probably it will not at once be admitted that this is the best means of measuring distortion; for no doubt it might be done in many other ways, and a method might easily have been selected which would have been less open to criticism on purely scientific grounds. We believe, however, the Kew certificate gives the information really required in practice. In order to determine if a lens is suitable for any particular purpose, all that is required to be known is whether the image of a straight line near the edge of the plate will show too much curvature, the amount of tolerance depending greatly on the work for which the lens is to be used. There is no means of enabling the photographer to form a judgment on this point more readily than by giving him the sagitta or sag in the image of a straight line along the edge of his plate. That it would be difficult to find a better method may, perhaps, be made more evident with the aid of figs. 17 and 18, the former representing a section through a lens and the photographic plate, and the latter showing part of the plate in plan, with the curved image of a straight line just inside its margin. In fig. 17 let N_1 be the nodal point of emergence; $S\beta$ the centre of similitude for rays emanating from a distant object and making an angle β with the axis; and S_β the same for an object at an angle θ; *e* and *g* will, therefore, be the images of these two objects as seen on the plate, whereas, if there had been no distortion, they would have appeared at *f* and *h* respectively; *ef* and *gh* will, therefore, be the total distortion in each case. In fig. 18, let the rays coming from the objects, of which the images are seen at *e* and *g*, make the angles β and θ with the axis of the lens at the nodal point; if *ef* and *eg* are equal in length to the lines similarly denoted in fig. 17, it is evident that the curve *ege* represents the image of a straight line, which, if there had been no distortion, would have appeared as the

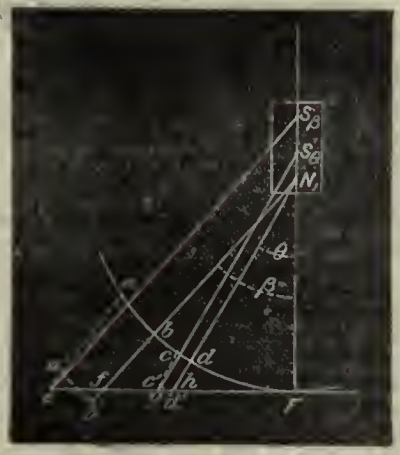

Fig. 17.

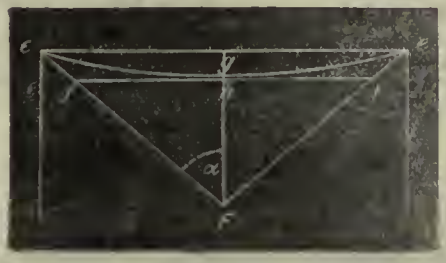

Fig. 18.

line *fhf*. Now, it would not have been difficult to have devised means of measuring the total distortion at any part of the plate; for instance, to have measured the distortion *ef* for the point *e* at the corner of the plate —but the following considerations show, it is thought, that that would not be a suitable way of testing the lens; let the curve *efe* in fig. 18 represent the greatest curvature that would be tolerated for the class of work for which the lens is intended; compare the lens producing this curve with another in which $S\beta$ occupies the same position, but in which $S\beta$ is nearer the nodal point N_1: *ef* would be the same in the two cases, but *gh* would be less in the second case, and the curvature would therefore exceed the tolerated limit; with two lenses giving an equal total distortion at the margin, one should be passed and the other rejected. The total distortion at any one point will not therefore give a measure by which the lens should be judged, the greatest rate of change in the distortion more nearly representing what is required to be known; and, as the rate of change is certain to be greatest at the margin, the Kew certificate supplies the information required.

The tourniquet has already been mentioned as an apparatus which has been specially recommended for the purpose of testing photographic lenses; by means of this invention, Commandant Moëssard obtains an excellent means of detecting distortion, but hardly of measuring it in a way to indicate the curvature produced in an image. It will be remembered that the lenses can be revolved about an axis which passes through the nodal point N_1, whilst the eyepiece remains stationary; the effect of this movement can be seen in fig. 17 by imagining the lens to be stationary, whilst the object and the eyepiece revolve about the nodal point, the arc *abcd*F being the path traversed by the eyepiece. Let *a* be the image of the object after the lens has been revolved through an angle β, and *e* the position where the image would be seen on the photographic plate; for there is no reason to believe that the line *ea* will coincide exactly with the line $eS\beta$; if there were no distortion, *b* would be the image as seen in the tourniquet, and the distance moved by the image from *b* to *a* is what is measured by that apparatus. It will be noted that the image *a* will be much out of focus if the lens has a fairly flat field, and that, after re-focussing, *a'* will represent the image, and *b'* the point from which the measurement is taken; this re-focussing will tend to reduce any error which may be due to *ae* not being coincident with $eS\beta$,

but such a movement in the middle of an operation is rather objection able on mechanical grounds, Putting this objection aside, it will be seen that we do not get a ready means of finding the curvature produced in the image as seen in plan in fig. 18; for, if $c'd'$ is the length measured by the tourniquet when the lens is revolved through an angle θ, then the sagitta of the curve is equal to

$$a'b' \text{ sec. } \beta \text{ cos. } a - c'd' \text{ sec. } \theta.$$

15. *Achromatism. After Focussing in the Centre of the Field in White Light, the Movement necessary to bring the Plate into Focus in Blue Light (dominant wave-length* 4420), = 0·—— *inch. Ditto in Red Light (dominant wave-length* 6250), = 0·—— *inch.*

The photographer may be said always to adjust his focus in daylight, and if the actinic rays are not brought to the same focus as the dominant rays for white light, the definition obtained in the photograph itself cannot be perfect. In fig. 19, let $u'wu'$ be the position of the photographic plate, the focus of which has just been adjusted in daylight; if the lens has not been properly corrected for achromatism, the different coloured rays will form different cones, and those coming to a focus at w will have a wave-length of about 5570, for that, I am informed by Captain Abney, is generally speaking, the dominant wave-length for white light. Let $b'bb'$ be the cone of rays of 4420 wave-length, which is not far from the position of the maximum actinic effect for dry ordinary bromide plates, and let $u'uu'$ be the cone for rays of 4000 wave-length; since the actinic effect with silver salts begins to fall off rapidly at about 4000 wave-length, the cones outside the cone $u'uu'$ may be neglected, and it may be taken that the image of a point covers a disc on the photographic plate of which $u'w$ is the radius. It is evident that what the photographer wants to know, with regard to the achromatism of his lens, is the amount of diffusion caused in the image by any errors in its construction, that is to say, what

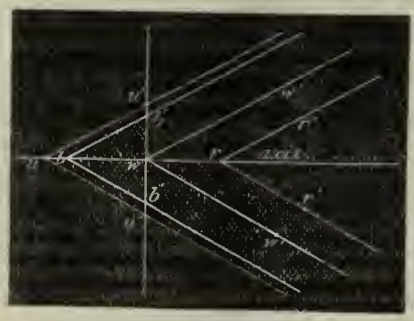

Fig. 19.

is the actual size of the disc of diameter $u'w$.

The examination for achromatism is, therefore, made in the following manner:—First the focus is carefully adjust in daylight on a suitable object placed as far away as possible in the room, and then the focus scale is read off. After this, a sheet of blue glass, the colour of which has a dominant wave-length of 4420, is placed behind the object and close in front of a small opening in the shutter, through which all the light enters the room; the focus is readjusted, the focus scale read off again, and the difference in reading to that observed in white light is noted; the length bw in fig. 19 is thus obtained. Now let f be the principal focal length of the lens; and let f' be the focal distance when the observation was made, which can be obtained with sufficient accuracy by a direct measurement from the ground glass to the nodal point of emergence, or to the pivot which has been made to pass through that point. The difference of focus bw, noted between the blue and white light, is then multiplied by f/f', and the result thus obtained is that finally recorded in the Certificate of Examination as if it were the direct result of an observation made on a distant object. Exactly the same process is then repeated with a sheet of red glass, the colour of which has a dominant wave-length of 6250.

The reason for multiplying the result of the observations by f/f' is, that it would evidently be unfair to test objectives of different focal lengths on a near fixed object, for in some cases the ground glass would be close to the principal focus, and in others, far removed from it. It seems, therefore, advisable to reduce all results, so as to make them equivalent to observations taken on infinitely distant objects, and this is done by applying this correction. An assumption is here made that the difference of focus between different coloured rays in the same lens varies directly as the focal distance, and this, in all probability, though not strictly accurate, introduces an exceedingly small error in the results.

The blue and red glasses, which were selected and measured for colour by Captain Abney, form a perfect contrast, as may readily be seen by placing them together, and observing how very nearly completely all light is excluded.

By simply noting the difference of focus recorded in the certificate between observations made in red and white light, or between observations made in blue and white light (the latter being of far more practical importance), it can at once be told if the lens is, or is not, well corrected for achromatism. But it would seem desirable, as already remarked, to form an estimate of the actual amount of diffusion produced in the image as a result of any error that may be detected in the chromatic adjustment of the lens. Now, there can be no difficulty in determining the size of the disc of radius $b'w$, for bw has been directly determined by experiment, and, since the cone $b'bb'$ represents the cone of rays of maximum actinic effect, on this disc will be concentrated the bulk of the rays which produce the effect on the photographic plate. But what we want in reality to find is the radius $u'w$, since that has been shown to represent more accurately the radius of the disc of diffusion; it may, however, be remarked that no fault can be found on this head with the method of testing, because the probabilities of error are lessened by taking the observation with rays of the maximum actinic effect. With a lens not at all corrected for achromatism, the length between the different foci for different coloured rays varies approximately as the difference of the squares of the wave-lengths of the colours in question; and, taking the wave-lengths as above given, uw will be found to be to bw as 5 to 4. But it must be confessed that this rule may have little or no relation to the truth with a corrected lens, and it is merely adopted as the only approximation obtainable. It is assumed, therefore, that $uw = 5/4\ bw$. Let bw, the result obtained by the examination for achromatism $= a$; let the diameter of the disc of confusion, or twice $u'w$, $= \delta$; let the principal focal length of the lens $= f$; and let the effective aperture $= \varepsilon$. Then it can be seen, by reference to fig. 6, that—

$$a = \tfrac{4}{5}\,\frac{f\delta'}{\varepsilon} = 8\delta'\sqrt{(\text{C.I. No. of stop})}.$$

The table elsewhere, which gives the values of $20\ \delta\sqrt{(\text{C.I. No. of stop})}$, affords a ready means of obtaining the required results in the following manner:—

Knowing the C.I. No. of the stop, decide on δ', the diameter of the maximum disc of diffusion that will be tolerated; then, under the columns thus ascertained, look out μ in the table, multiply the figure there given by $\frac{2}{5}$, and the maximum difference of focus, a that can be tolerated between white and blue rays is thus obtained.

Or, in the line opposite the stop of the size under consideration, find a number equal to a, the observed difference of focus for white and blue rays; then δ', the diameter of the disc of diffusion, will 5/2 times δ, the figure given at the top of the column in which a has been found.

It may be observed that either the principal focal length or the position of the nodal point of emergence may vary as different coloured lights pass through a lens. It would not be difficult to investigate these two sources of error seperately, but the results would be of little or no practical value.

16. *Astigmatism. Approximate Diameter of the Disc of Diffusion in the Image of a Point, with stop C.I. No.* —— *at* —— *inches from the Centre of Plate* = 0·—— *inch.*

The following is the method of examination for astigmatism:—The room is darkened, and in front of the lens is placed a thermometer bulb, thus obtaining, by means of the reflection of the light of a small lamp, a fine point of light. The lens holder of the testing camera is revolved upwards or downwards about the horizontal axis so that the axis of the lens makes an angle, ϕ, with the path of the rays coming from the thermometer bulb; the angle ϕ is such that the point of observation represents the extreme corner of the plate of the size of which the lens is being examined; that is to say, if, in fig. 20, GG represents the position of the ground glass, then CP is equal to half the diagonal of the plate; this angle has already been found for previous tests. If the lens shows any astigmatism, the image of the point of light can be made to appear, first as a fine vertical line, and then, as the focus is lengthened, as a fine horizontal line. The focal scale is read off at each of these positions, and the difference, γ, between the two readings gives a measure of the astigmatism. But, in order to judge of the amount of astigmatism that can be tolerated, the diameter, σ, of the disc of diffusion

caused thereby should be calculated. This is done by multiplying γ, the difference of focal distance of the focal lines, either by $\frac{f}{f'^2}\frac{\epsilon\cos\phi}{2}$ or by $\left(\frac{f}{f'}\right)^2\frac{\cos\phi}{20\sqrt{(\text{C.I. No. of stop})}}$, where ϵ is the effective aperture, f the principal focal length of the lens, and f' the focal distance when the observation was made. As the thermometer bulb is placed at the same

Fig. 20.

distance from the testing camera as was the object in the examination for achromatism, the ratio f/f' is exactly the same as in that case. The same result may be obtained by the use of the table in the following manner:—Find the value of δ, the diameter of the disc of diffusion, on the supposition that the μ of the tables has the value just obtained for γ; multiply the value thus obtained for δ by $\left(\frac{f}{f'}\right)^2\cos\phi$, and we get σ, the required value of the disc of diffusion due to astigmatism. This is the quantity recorded in the Certificate of Examination.

Fig. 21.

That this is the case can readily be seen by reference to fig. 21 Here AB represents the effective aperture, F_1 and F_2 the positions of the focal lines, and PH the position that the photographic plate would occupy. At F_2 the image appears as a fine line perpendicular to the plane of the paper, and at F_1 it is represented by the line ab; half way between these two points the rays cut the plate in the form of a disc, of which $a'b'$ is a diameter. Any movement of the plate from this position must lengthen out the disc of diffusion in one direction or the other, and this, therefore, is the position that the photographer naturally adopts as his focus. By similar triangles—

$$a'b'/AB = F_2C/F_2N_1 \text{ and } F_2C/CN_1 = F_2H/N_1P.$$

Therefore, since CN_1 and F_2N_1 are approximately equal,

$$a'b' = AB \cdot F_2H/N_1P, = \frac{\epsilon}{2f'}\cos\phi\, F_1F_2.$$

Now F_1F_2 represents γ, the movement of the ground glass, which was the measurement recorded. In the case of the examination for achromatism, it was shown that it was unfair to conduct the test on a near object without applying a correction, so as to make the result equivalent to an observation on a distant object, and that this correction could be made by multiplying the measurement recorded by f/f'. For the same reason, $a'b'$ must be multiplied by f/f' in this instance to obtain the true value of σ. Thus—

$$\sigma = \frac{f}{f'^2}\frac{\epsilon\cos\phi}{2}\gamma = \left(\frac{f}{f'}\right)^2\frac{\cos\phi}{20\sqrt{(\text{C. I. No. of stop})}}\gamma.$$

In considering the combined effect of astigmatism and curvature of the field, it should be remembered that it has been assumed that the photographer would focus his plate in the position PH, as shown in fig 21, and that the principal focal surface, PH, was a plane; this is, however, never the case. If the focal surface is curved, it is evident that the best general focus is obtained by observing the image of an object at a position about half way between P and C on fig. 21. In fig. 22, which is part of fig. 21 enlarged, let KL be the position of the plate when focussed in this manner, the distance between KL and PH being, therefore, due to the curvature of the field. Through b' draw $b'g$ parallel to F_2a'; then, by comparing this figure with fig. 6, it will be seen that eg in both cases represents the diameter of the disc of diffusion due to the curvature of field. Since, in fig. 22, fe represents the longest diameter of the ellipse of diffusion due to the combined effects of curvature and astigmatism, and since it is equal to the sum of $a'b'$ and ge, the diameters of discs of diffusion due to these two causes taken separately, it will not be unfair to look upon the evil effect of astigmatism as a simple addition to the evil effects of curvature. In using the table already given in the manner described, it would therefore be better if we substracted the diameter of the disc of diffusion due to astigmatism from the diameter of the maximum disc of diffusion which is to be tolerated, and use the difference as the δ in the table; we should thus get a more correct notion of the size of the stop that could be used to obtain any required standard of definition. The objection to this use of the table is that the astigmatism, that is, the distance F_1F_2, varies to a certain extent with the size of the stop used during the observation.

Fig. 22.

In the above discussion it has been assumed that the focal lines are sharply defined. If this is not the case, the reasoning here given is defective, because the distance separating the focal lines is then no indication of the amount of diffusion. An exaggerated idea of the amount of diffusion due to astigmatism may thus be obtained by the above method of calculation, for the disc may have only half the diameter thus found. Therefore, unless the focal lines are sharp—that is, unless the image of a point appears as a *very* thin line, first in one direction and then in another—no entry is made in the certificate.

Objections have been raised to the use here made of the term *astigmatism*, when it is intended to mean the effect of spherical aberration on oblique rays, it has been proposed to limit the use of the word so as merely to signify cylindricity in the lenses, such as might be produced by turning them in a lathe with elliptical motion. Whatever may be the theoretical value of this objection, we fear that the use of the term has been so thoroughly incorporated into the photographic vocabulary, both in England and abroad, that it would now be impossible to substitute another expression in its place.

Leonard Darwin, Major R.E.

(To be continued.)

DETECTION OF GOLD IN DILUTE SOLUTIONS.

It is well known (says Mr. T. K. Rose, B.Sc., in the *Chemical News*) that, if large quantities of boiling water are poured into a solution of stannous chloride, a yellowish-white gelatinous precipitate of tin hydrate is obtained. If the water contains a little chloride of gold, the precipitate is coloured red (purple of Cassius). A solution of one part of gold per million parts of water treated in this way gives a bright rose-coloured precipitate almost instantaneously in a small test-tube. One in four millions gives a paler colour easily detected in a test-tube if comparison is made with the precipitate caused by distilled water. For more dilute solutions a greater bulk of liquid is required, and the precipitation is best effected in beakers.

If 0·0000311 grm. gold (one-millionth of an ounce Troy) is dissolved in 3·11 litres of water, and the solution, containing one part per hundred millions, is raised to boiling and poured suddenly into a large beaker containing 10 c.c. of a saturated solution of $SnCl_2$ in water acidulated by HCl so as to mix the two liquids as rapidly as possible, a bluish-purple precipitate is obtained. This precipitate, when collected in a test-tube, differs markedly in colour from a precipitate obtained by pure water in the same way. There seems no reason why a still more dilute solution of gold should not yield a colour if precautions are taken to ensure the complete mixture of precipitant and solution.

Quantitative results based on comparison may also be obtained with care, as the precipitates are quite stable in water. The presence of NaCl (3 per cent.), $CaSO_4$, KCl, KBr, NH_4Cl, a little free HCl, &c., or all of these, do not interfere with the reaction. The precipitate is soluble in ammonia and is re-precipitated, showing its original colour, on neutralising with HCl. Synthetically prepared sea water containing gold to the amount of one in twenty millions (three-quarters grain per ton) is equally sensitive, but the colour is in this case a blackish rather than a purple violet. I am proceeding to test real sea water in the same way, though quantitative results cannot be expected, since Sonstadt states (*Chemical News*, xxvi. p. 159) that only a small portion of the gold present is precipitated by stannous chloride.

This modification of a very well-known test appears likely to be useful in chlorination mills, where it is often desirable to detect the presence of gold in liquids containing as little as 1 in 5,000,000. The most dilute solution that reacts if treated in the ordinary way by $SnCl_2$ is one per million (*vide* text-books, *passim*), and then only after a lapse of some hours.

RECENT PATENTS.

PATENTS COMPLETED.

IMPROVEMENTS IN OR RELATING TO HAND CAMERAS.

No. 21,553. SAMUEL WHITE ROUCH, 180, Strand, London, W.C.—*November* 5, 1892.

THIS invention relates to certain details in the construction of hand camera fitted with my plate changing appliances, working in separate reservoirs or magazines detachable from the camera, as patented March 17, 1888, No. 4145.

My improved hand camera may be described as follows:—I provide it with two or more lenses adapted to fit the same flange in the usual way, one of them being of short focus and capable of including a wide angle of view, the other having a longer focus. This permits of any desired amount of the subject that is to be photographed being included in the picture.

The camera, which, when in its normal state for wide-angle views is very small, may be distended to any desired length so as to suit the lens or lenses of longer focus; this being effected by means of a bellows or gusset body attached to the front portion to which the lens is fixed, and to the rear portion in which the sensitive plate or film is carried. The extending of the camera for adjusting the focus, is effected by a suitable rack and pinion. A ground-glass screen is not necessary for sharp focussing, as this can be equally well done by means of suitable scales graduated and engraved to suit the various distances at which either of the lenses is in focus.

My improved hand camera has a swing back of any suitable construction, and the front to which the lens is attached has a suitable sliding motion, as to permit of its being moved in either a vertical or horizontal direction.

The exposure of the plate is made by means of the band-shutter described in Specification No. 6613, 1887, placed behind the lens, and having an orifice which passes across the lens with any required degree of rapidity.

In the detachable magazine I provide an index of any suitable construction, which automatically registers the number of plates that have been exposed from the magazine. This index is moved by the action of the lever, which must be pressed each time a plate is exposed. When, by the indication of the register, the full number of plates contained in the magazine is found to have been exposed, the light-tight shutter of the changing back is closed, the magazine is detached, and another, containing a fresh supply of plates, can be inserted in its place.

The rapidity of the exposing shutter is determined by a spring which, when much braced up, gives the greatest degree of rapidity; but the tension may be removed from the spring by releasing the pawl of a ratchet, as usually employed in such shutters, and in this state the shutter moves with a slow action—caused by the relaxation of the spring. By adjusting the bracing-up of the spring, any intermediate degree of rapidity is obtainable, and when once set, the action is always afterwards uniform.

What I claim is the use in connexion with the camera described in my Specification No. 6613, 1887:—1. The employment of more lenses than one, these being of wide and ordinary angle. 2. Adjusting the focus of lenses by rack and pinion attached to the body of the camera. 3. Placing the shutter behind the lens and adjusting the power of the propelling spring in the manner described. 4. The graduated scale for showing when the lens is focussed for any particular distance of object. 5. The application of a swing-back. 6. The automatic registration of the number of plates exposed. 7. An arrangement for moving the lens front in either a vertical or horizontal direction.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 1,—Mr. A. Haddon in the chair.

A letter was read from the Photographic Society of Great Britain inviting the Association, as an affiliated body, to contribute examples of various printing processes to a series of albums which the Society have in contemplation. Consideration of the letter was deferred.

THE OLD METHYLATED SPIRIT.

Mr. L. MEDLAND said that recently, in reply to inquiry he had made at Somerset House, one of the officials waited upon him, and stated that permission would be given to him to obtain one gallon at a time of the old kind of methylated spirit direct from the methylator.

LANTERN SLIDES OF IRELAND.

Mr. F. W. HINDLEY gave a description of his experiences in the west of Ireland, illustrating his remarks by a large number of lantern slides made from negatives he had taken in the vicinity of the Connemara Mountains, Clare, Wicklow, Galway, and other places. Mr. Hindley, in allusion to the climate, said that between the showers the light was excellent, the greater brilliancy being due, he supposed, to the moisture in the atmosphere. He had used a hand camera throughout, most of his negatives being taken on films.

The slides shown embraced views of mountains, seascapes, studies of the peasantry, some of the hotels, the primitive coaches, beggars, priests, cattle, Irish shanties, castles ancient and modern, views at Kilkee, and many other "objects of interest." The series of pictures illustrated both the scenery of a large tract of Western Ireland as well as the principal characteristics of its poorer inhabitants, and was accompanied throughout by a running commentary and description of a humorous nature.

At its conclusion Mr. Hindley was thanked by the meeting, which was a large one.

Leeds Photographic Society.—December 1, Annual Meeting.—The report showed the present membership to be 105; the property of the Society, in appliances, furniture, and books, is now considerable; in photographic publications there is almost all the best books published, besides the current literature, annuals, &c., which are lent out to the members. The following gentlemen were elected Committee for next year:—Messrs. E. H. Jacob, M.A., M.D.; B. A. Burrell, F.I.C.; Godfrey Bingley; S. A. Warburton; Herbert Denison; Robert Steele; J. H. Walker; J. W. Thornton; H. P. Atkinson; T. Butterworth. Mr. GODFREY BINGLEY afterwards gave a lecture, entitled *Wanderings with a Camera in* 1892, illustrated by lantern slides.

Holborn Camera Club.—December 2, Mr. Fred. Brocas in the chair.—Mr. F. J. COBB gave a demonstration on the use of the optical lantern. Last Saturday the annual supper of the Holborn Camera Club took place at Anderton's Hotel, Fleet-street, Mr. Horsley Hinton in the chair.

St. Bartholomew's Hospital Photographic Society.—November 30, Dr. Russell presiding.—Mr. W. J. Armytage read a paper on *Daylight Enlarge-*

ments, in which he carefully explained the details of the making of enlargements by the use of an ordinary camera. After the paper there was an exhibition of prints and lantern slides by members.

Hackney Photographic Society.—November 29, Mr. W. A. Barker in the chair.—It was decided to hold a smoking concert on January 3 at the Club premises. Mr. Poole showed a P.O.P. print, which had been in the frame three weeks, but was not stained in any way. Mr. Beckett showed two prints, one on platinotype paper and the other on silver paper. Both had been kept in a very damp place. The platinotype print, however, was perfect, whilst the silver print had faded considerably. Mr. Wise and Mr. Houghton both showed flashlight pictures. Mr. Cross showed some negatives, and asked what was the matter with them. Mr. S. Beckett was of the opinion they were under-exposed and out of focus. Other work was shown by Messrs. Nunn, Moore, Soileau, &c. Mr. John Reynolds exhibited an Anschütz tachyscope, which was on the same principle as a wheel of life. Mr. TUNSTON asked how permanganate of potash is used as an intensifier, as per *Wall's Directory*. Mr. Beckett thought it stained the negative, and thus gave more printing quality. Mr. SODEAU, however, said there was a distinct chemical action. From the question box: "What constitutes a hand-camera picture?" Considerable discussion ensued on this question, in which nearly all took part. The Hon. Secretary gave the ruling of the Judges at the recent Exhibition, which was, "*Any* camera held in the hand is a hand camera." A vote taken on the question resulted in the following being the accepted answer:—"A hand camera *must* be held in the hand only, and *not* on *any* kind of *support*. Instantaneity is not essential, the natural limit being a question of how long it can be held as mentioned. If placed on a *stand* or any other support it is *no longer a hand camera*. Size is *immaterial*. Mr. R. BECKETT said he was of opinion that the composition should also be done upon the ruler. The Hon. Secretary stated that next meeting would be a lantern night.

Leytonstone Camera Club.—December 3, Mr. Tom Symmons in the chair.—A discussion on *Photographic Dodging* was opened by Messrs. H. H. Symmons and F. W. Wates. Mr. SYMMONS commenced his paper on the bugbear *Halation*, and after describing the various causes, went on to the remedies, advocating backing the plate with Vandyke brown in a creamy paste with water and a little glycerine; he also found, if only present in a small degree, it could often be removed from the negative with methylated spirit applied with a piece of chamois leather. The great care that the inside of the bellows should be dead black was next gone into, he explaining that that was frequently the cause of bad negatives, particularly when using a lens of greater covering power than the plate exposed. He also mentioned the advantages of using the front or back combination of a rectilinear lens which would be found about double the focal length of the doublet, and how often the extension of the bellows did not permit the opportunity of using it: and showed how he overcame the difficulty by having a piece of brass tubing made to extend the barrel of the lens when using the front combination. Mr. WATES here took up the parable, and went on to the question of improving or dodging negatives by means of intensification and reduction, demonstrating by means of Dr. Monckhoven's formula. He next described the means of ascertaining that the plate was in correct register with the focussing screen, and the means of detecting the presence of actinic light in the dark room. How to test the focal length of any lens and the value of any stops was next explained, and he also showed a very simple view-meter, and went into the different methods of vignetting, advocating tracing the outline with tissue paper, cutting out the shape on card, serrating the edge, fastening on the printing frame, and packing underneath with cotton wool. Pulling the wool out into fine shreds gave a very soft vignette, and also gave a ready means of at once slightly altering the shape, if necessary, when printing. Blocking skies and other printing dodges were next described. Five gentlemen were elected, making up the number roll to 123. The first annual dinner takes place on the 10th inst.

Kensington and Bayswater Photographic Society.—December 5, Mr. S. C. Mason presiding.—Three questions from the box were read and discussed. The first was in reference to the exposure required for snow pictures; the second as to whether it was possible that a fairly developer should produce a partial reversal of the image on a negative, as one of the members had a batch of negatives giving this result, and he could not account for it in any other way, as he was convinced that the exposure given was practically correct. The President stated that if by accident any tiny chamble got into the developer it would cause instantaneous reversal. The next question referred to enlarging from films. One of the members found that when he placed his film in the enlarging lantern it crinkled and became useless, even though he adopted the plan of safely pressing the film between two pieces of plain glass. It was suggested that this might have been caused by the films not being perfectly dry.

West Surrey Photographic Society.—November 30, Mr. James in the chair.—The subject of the evening was a demonstration of the uses of *Cresco-Fylma*, by Messrs. Hill Brothers, of Surbiton. The mode of procedure is as follows:—The negative is immersed in a diluted solution of the mixture (three parts of concentrated solution to one of water); in a very short time the film leaves the glass support. After this takes place it should be left in the solution for about two minutes, and then, supported by the glass it has just left, the free film is transferred to another dish containing simply water. Then the enlarging commences, and in about fifteen minutes it has reached its maximum growth of about twice its original size. The film is then floated on to its support, whether glass, porcelain, or paper, it matters not, the air bells blown from under the film, and then allowed to dry. After drying it is necessary to wash the film as in an ordinary negative or transparency. The enlarged film shows no signs whatever of distortion, nor loss of sharpness. In cases where the pyro solution in developer had been used, enlargement took place less readily and did not proceed so far. It was also pointed out by Messrs. Hill that, if the subject is badly placed upon the plate, it may be slightly enlarged and shifted on the same plate. In the discussion it was pointed out that the patentees seemed to have given their attention only to the enlarging properties of their solution, and had neglected the fact that they could procure a perfectly uninjured free film, which fact alone should make their article invaluable. Again, workers of the carbon process will find this solution a great boon, inasmuch as the tedious and uncertain double-transfer process can be made as simple and as certain as the single transfer. All that is needed is to float the film of the negative in a very dilute solution of "cresco" to avoid enlarging, and then reverse the film on to another glass. When printed, the result would, of course, be the same as if finished by the double-transfer process.

West Kent Amateur Photographic Society.—December 3.—Mr. A. R. DRESSER gave a lecture on *Amidol and Its Uses*. The lecturer said that he found this developer very good for negative work, bromide paper, and lantern slides, it behaving exceedingly well with bromide paper printing and enlarging from very dense negatives. The developing formula sent out by makers he soon gave up, it very soon turning colour, and after making several experiments he struck upon the following formula, which worked well:—Amidol, 1 ounce; meta-bisulphite of potassium, 1 ounce; water, 10 ounces. To use with this Mr. Dresser makes up a saturated solution of washing soda, a saturated solution of carbonate of potass, and a ten per cent. solution of bromide of potassium. He recommended a start with developer as follows for plates, normal exposure:—Amidol, 1 drachm; saturated solution of washing soda, 1 drachm; water, 1 ounce; and 2 drops of ten per cent. solution of bromide. This will also answer well for lantern plates. For extra density add a few drops of carbonate of potass solution as required. Formula for bromide papers:—Amidol solution, 6 drachms; carbonate of potass solution, 6 drachms; water, 10 ounces; ten per cent. solution of bromide, 30 drops. The lecturer recommended a trial of this developer, and handed round some prints and slides he had obtained, which showed good results.

Croydon Camera Club.—December 5, the President (Mr. H. Maclean, F.G.S.) in the chair.—Mr. W. H. Smith demonstrated, to a good attendance of members, who appeared keenly interested, the various ways in which glycerine may be used in conjunction with the oxalate developer in platinotype printing. The working of the oxy-magnesium lamp was also shown. Inasmuch as it is available for printing in silver as well as platinotype, the President remarked it was a matter for wonder that the profession did not make more use of it. Mr. Smith stated he had successfully used the lamp for portraiture, exposure being three seconds, marking at *f*-8.

Croydon Microscopical and Natural History Club (Photographic Section).—December 2, Mr. W. Bulgen in the chair.—Subject, *Blocking out and Printing in*. The Chairman, after introducing the subject, passed round a set of prints illustrating the various difficulties encountered when printing in clouds, &c. Various methods were then described, showing how they might be overcome by the judicious use of tissue paper and masks, or by printing with oil colours on the back of the negative. The addition of figures to a landscape on albumen paper did not present any special difficulty if the figures were first printed and then, after they had been carefully painted over with Indian ink, the landscape printed. When gelatine paper was used, a mixture of gamboge with turpentine or other medium which did not affect the gelatine was suggested in place of Indian ink.

Bath Photographic Society.—November 30, Mr. Austin J. King (President) in the chair.—He drew attention to the examples of work sent for exhibition that evening, which included many beautiful specimens, and which would be examined with interest. Some time was then profitably spent in viewing the various exhibits of the members' work during the summer. The remainder of the evening was devoted to displaying lantern slides. Mr. Braham showed two photographs he had taken from a balloon: one ascending, altitude 4200 feet; the other descending, altitude 6000 feet. And he gave a brief account of his aerial journey, pointing out that for map work by balloon photography above 6000 feet from the earth a peculiar fogging or obscuration was manifest.

Burnley Photographic Society.—November 30, Mr. John Butterworth (President) in the chair.—Mr. Buchanan Wollaston, of the Platinotype Company, gave an address on *The Development of Platinotype Prints*. He showed by means of experiments not only how various tints up to sepia might be obtained, but how the development might be retarded by glycerine.

Derby Photographic Society.—November 30, Mr. Richard Keene in the chair.—Captain W. de W. ABNEY, C.B., F.R.S., read a paper on *Hand Cameras and Shutters*, and prefaced it by remarking that, as President of the Society, he had great pleasure in coming amongst them, in response to the kind invitation which they had given him. Although the tie which formerly bound him to Derby was almost broken, still he could never forget that he was a Derby man and owed a very great deal to Derby and Derbyshire. Captain Abney then proceeded with his subject, remarking at the outset that, had he known previously that there would have been such a large sprinkling of ladies in the audience, he should have endeavoured to impart into his paper more matter which would have interested them in particular. When one went to London, one was apt to look at the scientific side of things more than the artistic side, but in the paper which he was about to read to them he had endeavoured to blend the two sides together. The Captain then went on to speak of the use of the camera and how to manipulate it so as to get the best possible results in various positions. He said he wanted to make it understood that a small ordinary camera might be made something more than a mere toy, and should be made to do some very serious work. The simpler the form of the camera, the better it was likely to be. One important question which often came to the ears of photographers of experience was as to whether movement was detrimental to the production of a clear, sharp picture. Some people said it was, but he was afraid the persons who said so argued without knowing the facts. If motion was applied to the whole camera and equally distributed, it was just as possible to obtain a good sharp photograph as though the camera had remained quite still; but, if the motion were unequal, one end of the camera moving without the other, then the picture was robbed of its sharp outlines. Captain Abney went on to say that some of his best pictures had been obtained on a dull day, and in describing the use of the hand camera, the importance of gauging distance, and the use of the bubble, he said that he had frequently used his umbrella as a camera stand, or even his walking stick. The lecture,

which was most interesting to all lovers of photography, was illustrated by means of the oxyhydrogen lantern, and some very good diagrams, illustrative of the remarks made, were passed round amongst the audience. At the conclusion of the paper a hearty vote of thanks was accorded to Captain Abney for his kindness in being present and giving such valuable information to the members of the Society.

Maidstone Amateur Photographic Society.—December 1.—Mr. ANDREW PRINGLE gave an address on *Lantern Slide-making*. It embraced a thoughtful *résumé* of the artistic aspect of the subject, later on turning to the scientific side of tonality and gradation. The various processes of slide-making were then discussed, and information given on the practical working of many points in reply to questions. Mr. Pringle concluded by specially emphasising the qualities of a good lantern slide, and spoke in favour of a medium tone neither too cold nor warm, and the necessity for all the details of the shadows being clear and visible on the screen.

Leith Amateur Photographic Association.—November 29, the President (Mr. Wm. Macdougall) in the chair.—The Secretary displayed one of the latest aspirants for public favour the "Developer," in demonstrating which he stated that this idea of developing an exposed plate in ordinary protected light was one which had taxed the abilities of many men, and this one, if carefully used, would do all that it claimed to do. The arrangements were neat, and the whole thing was well made, and might suit many who had not the usual dark-room appliances. Being the annual exhibition meeting night, the members occupied themselves with examining and criticising each other's work. Our correspondent says: "One of the things to be noted and objected to in this body's work is the apparent contentment to copy engravings of well-known pictures, such as Maclise's *Origin of the Harp*, Sir Noel Paton's *Oberon and Titania*, as well as Thos. Faed's *Tam O'Shanter*. Were those subjects taken from the original pictures, with the many difficulties attending such reproductions, there might be less need to notice such work; but copied as they are from ordinary black and white engravings, and well executed as they are, they should only be a stepping-stone to the much higher efforts of attacking the original pictures. There is one example of such a kind by the late David Scott in the Trinity House of Leith which I do not recollect of being reproduced in any but the most ephemeral form, *The Rounding of the Cape of Good Hope by Vasco de Gama*. Let some of the enthusiasts of this Society try that, and, if they succeed, they will have achieved a new honour to themselves and the Association they represent. The more noticeable exhibits were those of Mr. Guthrie, whose enlargement, *Newhaven Fisherman blowing his Baccy*, was fine, the President's clever groups, and Ewart's studies of children. Some fine examples of work were exhibited by E. A. Davies, Campbell, Hendric, and Goodall, and the entire show betrayed no falling off from the previous high standard of this Society's work. Again, may I draw this Association's notice to the desirability of their meetings coinciding with the issue of the yearly ALMANACS, which are the notifiers and recorders of the current office-bearers and meeting dates of the principal societies throughout the world? It would be welcome to all concerned."

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the EDITOR.

SIR,—As a reader of your valuable paper, I have noticed your general remarks tend to help on photography, whether practised by individuals—amateur or professional, or societies and clubs—and, in the same spirit, as a comparatively recent recruit in the ranks of amateur photographers, I have been somewhat crushed by the thought that possibly merit is not the only requirement for success, and such being the case, I am afraid to prepare work for the Exhibition of next year, having no hope of success. I have been led to this conclusion by the result of the Exhibition of the South London Photographic Society, held just recently. I was not an exhibitor, therefore my opinion is perfectly unbiassed, and I do not give it altogether as an opinion, but am rather seeking information by asking the following questions:—Was it right to expect the Judges (gentlemen of good stature and fine physique) to grope about on the floor to find work—pronounced "good" by many members, but which they could not possibly judge well under such peculiar arrangements as these? Is it usual for the Judges to have in their hands catalogues which give the number and name of exhibitor clearly set forth, when the conditions distinctly stated: "Names of competitors will be covered during judging?" The lantern slides were splendidly shown; but why, Mr. Editor, were some of them hurried through, and others kept on for a few momenta to wait for the applause, and why were some omitted altogether without a reason being given? As an amateur of about two years' experience, my pictures were not anywhere near good enough to be classed with numbers of those which had no opportunity of being appreciated by reason of their separation from each other—some on the ground, some hung where they could not be seen, here and there, on the "find-them-who-can" principle; and my contention, expressed by many others also, is that tactics like these tend to keep such as myself from attempting to join the army of conscientious artists, who desire to make their profession an art, and who look to the expression of the honest judgment of the many (rather than the opinion of acquaintances) as a means to their attaining that end. This cannot be done, nor our Societies make real progress, unless all have the opportunity to receive either compliments or criticism, and, surely sir, this was not the case in the Exhibition under notice. I have purposely avoided writing anything that might have caused pain to individuals, but I believe a little wholesome criticism from abler pens than mine may conduce to true "progressiveness" in the Society, which I hope will strive to encourage others who, like myself, could sign themselves as persevering and ambitious, in its highest sense.—I am, yours, &c.,

YOUNG MEMBER.

December 3, 1892.

"THE SPEED OF PLATES."

To the EDITOR.

SIR,—In justice to ourselves, we should like to refer more fully to the correspondence that you published last week under the above heading.

The plates of which we advertised the rapidity were tested, not by us, but by a competent independent gentleman, Mr. Alfred Watkins.

The sensitiveness reported to us was 150 on "Watkins' scale," and we considered we were quoting an accepted published ratio in stating that 150 "Watkins' scale" equalled 100 on Hurter & Driffield's.

So soon as Messrs. Hurter & Driffield raised any doubt as to the accuracy of the figures on their scale, we immediately withdrew their name from our advertisements, being quite content to accept the reading of the "Watkins' scale" alone, especially when given by such a *practical* expert as Mr. Watkins. We do not care to adopt the Hurter & Driffield actinograph until it is recognised as a standard instrument, by the Photographic Society of Great Britain, or by a suitable body of scientific men capable of deciding its merits. The mere fact of its being adopted by one or two plate-makers has no influence with us whatever. Meanwhile we are satisfied to have our plates tried by the "Watkins'" method, being the only *one* based on an actual camera test, we estimating that 999 plates out of 1000 *are* used in the camera. The whole question of branding the sensitiveness of plates on each packet is a most serious one, both to the manufacturer and to the trade.

As manufacturers we have nothing to fear in the future in respect to rapidity if we branded our plates, but the interests of the trade must be considered.

The system of branding plates adopted by manufacturers using Hurter & Driffield's actinograph may be fair to the purchasers, but are most unjust to the trade (both wholesale and retail), that *stock* their plates. Our plates, if *branded* this week 100 Hurter & Driffield, would be at a heavy discount (practically dead stock) if we were to issue 125 next week. Who ought to bear such a loss? Surely not the trade who stocked our goods, on our representations of only a week since.

Our company will not adopt any system of branding plates that is detrimental to the trade's interests. When it can be clearly shown us that the branding of plates would be advantageous to the trade, we shall be only too pleased to adopt their views.—We are, yours, &c.,

THE IMPERIAL DRY PLATE CO., LIMITED,
T. E. H. BULLEN, *Secretary*.

Cricklewood, London, N.W., December 5, 1892.

LANTERN SLIDES OF LIFE AND CHARACTER.

To the EDITOR.

SIR,—I am desirous of obtaining studies of life and character in all parts of the world, and, although I know it is a tall order, yet venture to utilise your columns (with your kind permission) to make known my yearning desire. First, however, I don't want something for nothing, but for every slide sent me an equivalent will be given. My offer is to give slide for slide. Any of your readers who may be in possession of hand-camera studies of street life, native characters, or scenes which will illustrate the life of that particular country, I should be glad to hear from. I will exchange any number (not exceeding eighteen) slides of English street life and character for a corresponding number from a foreign or colonial fellow-worker.

Although hand-camera shots would be preferred, as giving better renderings of life, yet I by no means wish the series thus limited. My object is to form a set of slides of an interesting and instructive nature, which will be ready for use by next season. I should be glad to hear from any one in this country as well who may possess suitable slides taken by them on a holiday trip abroad.—I am, yours, &c.,

47, *Hagley-road, Birmingham.* WALTER D. WELFORD.

MESSRS. HURTER & DRIFFIELDS' PAMPHLETS.

To the EDITOR.

SIR,—We are sorry that Mr. Cresswell has had the trouble of making the explanation which appeared in your issue of last week, and we beg to inform those who have made inquiries from him, and others interested,

that we have a *limited* number of reprints of our papers on "Photo-chemical Investigations and a New Method of Determination of the Sensitiveness of Photographic Plates," and on the "Relation between Photographic Negatives and their Positives." These reprints we shall be pleased to forward to applicants on receipt of names and addresses.—We are, yours, &c., F. HURTER.

Appleton, Widnes, December 5, 1892. V. C. DRIFFIELD.

EAU DE JAVELLE OR OZONE BLEACH.

To the EDITOR.

SIR,—Your correspondent, "S. V. W.," will find, in THE BRITISH JOURNAL OF PHOTOGRAPHY for 1885, page 124, instructions for making this. As he may possibly not have the volume, I give the particulars. Take four pounds of washing soda, and pour on it one gallon of boiling water; continue boiling till all is dissolved. Remove from the fire, and add slowly, with continued stirring, one pound of fresh chloride of lime, free from lumps. Allow to cool, and strain off the white, insoluble residue. The fluid should be kept in stoppered bottles. If this is to be used for prints after fixing, one drachm should be added to eighteen ounces of water.—I am yours, &c., CLIFFORD E. F. NASH.

[The above particulars appear in an article by Dr. Ellerslie Wallace on the "Elimination of Hyposulphites." At page 784 of the last ALMANAC appear two formulæ for the preparation of Eau de Javelle and Labarraque's solution. Whether either of these is identical with Holmes' Ozone Bleach we cannot say, but they answer the same purpose.—ED.]

PURITY OF OXYGEN.

To the EDITOR.

SIR,—The employment of oxygen for the limelight and other purposes has increased enormously since the commercial introduction of the Brin method, by which the gas is separated from atmospheric air by a now well-known chemical process. The gas so obtained is practically pure, analysis showing that, as now supplied by the Brin companies, it contains on an average 95·0 per cent. of oxygen, the remaining 5 per cent. consisting of inert nitrogen.

The success of this comparatively new industry has been so marked, that, as a natural result, competitors with rival processes have come forward. Some of these met with failure at an early stage of their career, but others are supplying oxygen to the public. This is by no means a state of things to be deplored from the consumer's point of view, if the product from the one source is as good as the other, for benefit generally arises from healthy competition. But when the rival product turns out to be, not oxygen, but a half and-half mixture of oxygen and air with a slight excess of the latter, the competition is of a decidedly unhealthy character, and is correspondingly bad for the consumer. I recently obtained a sample of gas from a dealer, which on testing (with a Hempel absorption pipette charged with metallic copper and ammonia) I found to be a mixture containing only 60·6 of oxygen. I next tested the illuminating value of this highly diluted oxygen with a limelight jet, and, for sake of comparison, placed by its side a precisely similar jet supplied with Brin's oxygen, and, as might have been expected, the light given by the former was little more than one half as intense as that afforded by the latter. With the good oxygen the lime was quickly pitted, whilst the other showed no sympton of destruction. It is also to be remarked that the consumption of the diluted gas is, for a given period, about one-third more—striving with both jets to get the best possible light—than that of good oxygen. On the same principle, a mountaineer at a high altitude will pass more (rarefied) air through his lungs in a given time than he will when he is in the valley breathing that which contains the normal quantity of oxygen.

As this matter is of great importance to many workers, I trust you may be able to find room in your valued publication for these words of necessary caution.—I am, yours, &c., T. C. HEPWORTH,

Author of the "Book of the Lantern," &c.

45, St. Augustine's-road, Camden-square, N.W., December 6, 1892.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange a Dallmeyer 2a lens for a Dallmeyer 4D; difference adjusted.—Address, MCISAAC & RIDDELL, Studio, Oban.

Will exchange 18×12 hot-rolling machine by Bury Brothers for Vanneck hand camera.—Address, W. WALKER, 156, Nocl-street, Nottingham.

Wanted to exchange *carte* lens by Squire, in good condition, for 10×8 or whole-plate portable rectilinear lens, adjustment by cash.—Address, EVERARD CUZNER, White Rock Studio, Hastings.

Will exchange rapid 10×8 portrait lens in good condition for 9×7 Optimus cenyscope lens in similar condition. Specimen of work sent.—Address, J. K. SMITH, Little London, Rawdon near Leeds.

Wanted, photographer's show-case, brass scales on stand, also posing chair. Will give in exchange superior cabinet rolling machine and scenery background, also mechanical negro and harp.—Address, A. D. CLARKE, photographic artist, &c., Pailton, Rugby.

PHOTOGRAPHIC CLUB.—December 14, Members' Open Night. *Demonstration of Paget Printing-out Opals and Lantern Slides.* 21, *Amidol and Other New Developers.*

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB.—December 14, Mr. T. Charters White, M.R.C.S., will give a demonstration on *A Simple Method of Photo-Micrography*, with lantern illustrations.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Ordinary Meeting, Tuesday, December 13, at 50, Great Russell-street. Major Darwin, R.E., M.P., will read a paper on *Lens Testing at Kew.* There will be no Technical Meeting in December.

IN the *Gazette* of 25 ult., containing the names of Volunteer officers who have received the decoration for long service, appears the name of Major J. Pattison Gibson, 18th V.B. Northumberland Fusiliers, who this month completes his thirty-third year of Volunteer service.

THE BENEVOLENT.—A committee meeting was held on Monday, December 5, in the rooms of the Photographic Society of Great Britain, Mr. W. Bedford in the chair. There were two applications for assistance, both in money and in finding situations. Both cases had been investigated by the Secretary and by a member of the committee, and the applicants attended and were interviewed by the full committee. In both cases the desired loans were granted. The Secretary reported on the disbursements of the moneys granted at the last meeting, and was able to report favourably on the progress of one or two men who have during the past few months been rescued from desperate straits by the Association. The Secretary was instructed to write to all subscribers of the Association who did not subscribe for the present year, asking them to continue their support, as the pressure of the season is being keenly felt by many photographers. The Secretary also reported that certain overcoats and boots which had come to hand had been highly appreciated by men who were in great difficulties, and asked the members present to supply certain other articles of clothing, which amongst them they were able to promise.

A NEW "shortened telescope," constructed by Dr. R. Steinheil, is (says *Nature*, described in the *Zeitschr. für Instr.* for November. The principle resembles that adopsed by Dallmeyer and Dr. A. Steinheil in their tele-photographic objectives. A negative system is introduced between the object-glass and the eyepiece, thus increasing its equivalent focal length. If a be the focal length of the objective by itself, r its distauce from the negative lens, and the magnification m times that produced without the negative lens, the total length of the tube is given by $l = r + m(a - r)$. In a telescope actually constructed on this system, the object-glass has a focal length of 16·2 cm. Its distance from the nearest surface of the negative lens was 12 cm., the equivalent focal length 60·8 cm., and the total length 27·8 cm. Hence the magnification was 3·75 times that obtained by using the objective alone. In this case, then, a magnification of 22 diameters was obtained with an effective aperture of 4 cm., a total length of 27·8 cm., and a one-inch eyepiece. If the same magnification and illumination had to be obtained by a long-focus objective, the length would have to be 60·8 cm. Thus the length is reduced by more than one-half without the usual disadvantages of short telescopes and eyepieces of high power.

ABSORBING POWERS OF DIFFERENT COMPOUNDS.—Of one heat ray of a burning lamp it is stated that there will be absorbed by passing through:—

Rock salt (colourless)	8 per cent.
Fluor spar	28 ,,
Flint glass	33 ,,
Glass used in the manufacture of mirrors	61 ,,
Calcareous spar	61 ,,
Rock crystal	62 ,,
Citric acid	89 ,,
Alum	91 ,,
Sugar candy	92 ,,
Ice	94 ,,

The difference in the behaviour of heat and light rays is strikingly shown in the case of common copperas, which absorbs all heat rays, but allows the easy passage of the blue rays. A watery solution of album will absorb nearly all heat, but to a very small degrees only the actinic rays, whereas an alcoholic solution of iodine absorbs the greater parts of actinic rays, permitting the passage of the heat rays. The loss of the actinic power of light in its passage through different kinds of glass is said to be as follows:—

	Thickness in Centimetres.	Loss per cent.
German window glass	0·15	4·2
Crystal	0·3	8·6
German plate glass	0·3	13·0
English crown	0·3	13·0
Frosted glass	0·15	50 to 60
Matt glass	Ground glass.	12·5 to 17
Orange yellow	0·12	51
Green window glass	0·15	82
Deep ruby	0·25	90
Opal	0·15 to 0·3	60 to 70
Porcelain	0·15	97

The loss of actinic power varies with the quality of glass employed. Greenish glass, if ever so slightly tinged, will absorb from two to four times as much light as glass of the colour of pure water. The loss of actinic power amounts, as a rule, from three to ten per cent. for each millimetre of thickness, the rays of light striking the glass perpendicularly.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

*** Editorial table and several other communications in our next.

J. A. FORREST.—Received. Thanks.

W. S. LILLY (Lincoln).—The example of collotype work sent is excellent.

F. J. GARRISON.—Mr. H. N. King's address is 4, Avenue-road, Goldhawk-road, W.

T. BRAMWELL (Alston).—No doubt the lens would answer for the purpose. The heat of the lantern would, in all probability, not affect it.

S. TALLON.—You will find a reference to the sulphurising of asphalt, by Herr E. Valenta, at p. 614 of the volume of this JOURNAL for last year.

J. PIKE.—A copy of Liesegang's *Manual of Carbon Printing* might possibly be obtained by advertising for it. We can suggest no other course.

W. BLEASDALE, of St. Helen's, asks: "Would you please inform me where I could get good carbon transfer paper?"—Of the Autotype Company, 74, New Oxford-street, W.

HANTS.—If you can prove there is no novelty in the invention, and that it was in use prior to the date of the patent, you can make the apparatus, as the patent is not a valid one.

T. WILCOCKS.—The manual on the carbon process, published by the Autotype Company, will give every particular. If any difficulties are experienced in working it, we shall always be pleased to advise.

HENGIST.—If you send in pictures for competition, representing them to be what they are not, and a prize is awarded for them, the prize is obtained by misrepresentation, which may be construed into a fraud, and might subject you to a prosecution.

G. B. ASTOR.—The work to which you refer is by Mr. Chapman Jones, and is published by Iliffe & Son. Mr. Chapman Jones is a sound writer, and any statements made by him can be relied on. The title of the book is *Introduction to the Science and Practice of Photography.*

N. M. M. asks: "Can you tell me where I can get a book on sunk mount cutting?"—A work on this subject was published by Kent & Co. some years ago, but whether it is in print now we cannot say. Its title, if we remember rightly, was *The Carver and Gilder's Guide.*

T. OFFER.—The cause of the fading is very likely indeed to be due to the hyposulphite of soda. For four shillings per cwt. hyposulphite of soda fit for photographic purposes must not be expected. It may answer very well as an anti-chlor in paper-making, for which it was very probably sold originally.

PERPLEXED.—The print is by the Meisenbach process. That and cognate methods of book illustration are referred to in the editorial article of the forthcoming ALMANAC. The screens are not, we believe, obtainable in England. Wolfe, of Dayton, Ohio, U.S.A., and some Continental firms, supply them.

C. SCHMIDT (Dresden) asks if there is any varnish for negatives known in England that can be applied without the negative being warmed; and, if so, how it is made.—Such a varnish is well known here, and it is simply a solution of Dammar resin in benzol. The better the quallty of the resin and the solvent, the more satisfactory will be the varnish.

W. GIRLING.—White blinds will be best for the north side of the studio. For the south side, dark ones, such as dark blue or green, and of a thicker material, will be preferable. As the south side is already glazed, we should not advise its being blocked up if good-fitting blinds are provided, as for certain effects the light may at times prove useful.

S. TABRUM complains that, in making collodion for enamelling prints, the collodion is much too thick to flow over the plate, although only half the quantity of pyroxyline generally recommended was used, and the addition of more ether and alcohol does not make it much better.—The pyroxyline is of an unsuitable kind or the purpose, and the remedy is obvious.

S. A.—The albumen process has so often been described, and full working details given, in these columns that they cannot be repeated, at least for the present. The reason why the process is not worked more generally is that it involves more trouble and requires more experience than most other processes. Even if the plates could be purchased ready for exposure, like gelatine plates, the method of development and toning would have to be learnt, as it differs entirely from the treatment of gelatine plates.

FADING writes as follows: "I enclose two silver photographs which have faded badly in a few days. I have many prints like this recently, and cannot understand it. They are fixed and washed in the ordinary manner, as I have done for years. I should blame the paper did it occur in all; the paper is home-sensitised. Hypo soda from Marion's; silver bath, fifty grains; fixed from ten to fifteen minutes. I should be glad if you can suggest cause. During past season I must have sent out dozens, none probably as bad as these. These now sent were printed last week only."—This is one of the worst cases of spottiness we have seen to occur in so short a time. Possibly the evil may be due to the mountant or the mounts, which are printed in bronze. Our correspondent should test the latter, or, if he is not capable of doing it himself, send them to an expert for analysis. Bronze powder is a very prolific source of spots, and should always be avoided.

DEVONSHIRE says: "About two years since I saw in the JOURNAL a capital mountant; it was rice flour, with instructions how to make it for keeping for use. I cut the paragraph out, and carefully put it away for future use, but now cannot put my hand upon it. Can you give me particulars?"—We don't remember the article for the moment; but, if a paste be made in the same way with rice flour as with wheaten flour, it will answer quite well. A few drops of oil of cloves may be added as an antiseptic.

J. E. C. says: "A quarter-plate camera of mine has extra long extension. The leather bellows have at the smaller end, just behind the lens, developed a crease where there should not be one, the result being sagging of the bellows, and cutting off part of the picture when using wide-angle lens. Could I stiffen the bellows by a coat of glue, isinglass, &c., applied internally? If so, what do you think would be the best thing to apply?"—Possibly the best means of stiffening the bellows would be by the insertion of a piece of cardboard.

UNDECIDED.—For taking such a group as a football club, while it is always best to employ a lens specially constructed for the purpose, yet are good pictures produced by lenses of the cemented rapid type. Some photographers, whose means are rather limited, make use of landscape lenses for the purpose, but these necessitate a longer exposure than would be necessary with the former class. Of course, if both of the classes of lens, a group and a landscape, are worked with stops of the same relative apertures, the exposure will be practically equal. For such a subject as that mentioned a more pleasing picture will be obtained by placing the camera at a distance from the figures, using a lens of moderate angle, than when employing a wide-angle lens nearer at hand.

R. T. says: "A little while ago I had a sitter to take cabinet size, and, she being a fine subject, I took a 15 × 12 negative on my own account that turned out a fine picture. I offered the portrait to the lady's friends for half my usual price, but they declined to purchase; so I have used it as a specimen in the window, and also have a print in a show-case. Now the father of the lady threatens me with legal proceedings if I do not stop showing the picture. Will you please tell me if he can do so, as I made no charge for taking the portrait?"—This is a point that, so far as we are aware, has not been contested. But we think there is very little doubt that, if proceedings were taken, an injunction would at once be obtained, and the defendant would find himself involved in heavy costs.

W. R writes: "I shall be glad if you can give me a little help. I have been making wet-collodion transparencies in the camera, and have succeeded very well, except for one defect, which more or less impairs the quality of nearly all the slides, viz., crapy lines running diagonally across the plates. I rock the plates and let them set well before sensitising. I am using ——'s negative collodion, with iron development and a substratum of dilute albumen. I never used to meet with this trouble in the old wet-collodion days, so that I cannot account for it."—Crapiness is usually due ro an unsuitable pyroxyline in the collodion, or its being made with too weak solvents. But this is scarcely likely to be the case with the collodion named, more particularly as some of the pictures are free from the defect. Try the effect of coating the plates more slowly—that is, allowing longer time before the plate is brought to the vertical position—and do not rock so quickly.

WEST LONDON PHOTOGRAPHIC SOCIETY.—December 13, General Discussion on Photographic Subjects.

MADDOX FUND.—A sum of 4*l.* 17*s.* 5*d.* has been received towards the above fund from the Photographic Society of India.

LONDON AND PROVINCIAL HOTOGRAPHIC ASSOCIATION.—December 15 Monthly Lantern Night. 22, Ordinary Meeting.

MESSRS. FUERST BROTHERS are now issuing amidol in cartridges. One tube contains sufficient of the reagent to develop ten half-plates.

FORTHCOMING EXHIBITIONS.

1893.	
February 18.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb, 100 High Holborn, E.C.
March 1, 2	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
April 17-29	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

CONTENTS.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1702. Vol. XXXIX.—DECEMBER 16, 1892.

OUR 1893 ALMANAC.

The British Journal Photographic Almanac for 1893 is now in course of publication. It contains a larger number of pages, devoted respectively to the text and to commercial announcements, than any previous volume, the exact number of pages being 1236, an increase of sixty-eight on last year.

The editorial article is devoted to "Some Photographic Methods of Book Illustration," and includes practical details of the principal photo-mechanical processes in modern use. Among the contributors to the volume are Captain Abney, Professor W. K. Burton, Mr. R. H. Bow, C.E., Mr. Andrew Pringle, Mr. Thomas Bolas, Mr. Chapman Jones, Mr. George Davison, Mr. C. H. Bothamley, Mr. Thomas Bedding, Mr. W. E. Debenham, Mr. G. Watmough Webster, Sir H. Trueman Wood, Mr. W. B. Bolton, Dr. R. L. Maddox, Mr. B. J. Sayce, Mr. E. W. Foxlee, Canon Beechey, and about 150 other well-known writers and photographic experimentalists. The information contained in the section devoted to formulæ has been revised and brought up to date.

The volume is enriched with an example of collotype printing by Messrs. Morgan & Kidd, a specimen of Mr. Henry Sutton's half-tone process, one of Messrs. Waterlow's process, and three Meisenbach reproductions of negatives by Messrs. H. M. Hastings, J. B. B. Wellington, and E. Woodward.

A TELESCOPIC FOCUSSING FINDER.

Since the system of focussing the image in the camera by means of a pocket telescope was brought before the public at the first, or Derby, meeting of the Photographic Convention in 1886, nothing has been said about it in these pages; but, as queries have of late been coming to us concerning it, we think it well to revert once more to the topic. For the benefit of the numerous body who have adopted, as amateurs, the practice of photography since the date mentioned, it may be well that we commence what we have to say by recapitulating the general nature of the system and its special advantages over the ordinary means of focussing, at least under special circumstances.

These circumstances are those which when employing a small or hand camera find their analogue in one of the duplex or twin type, that in which there are actually two cameras conjoined, the lenses of both being similar and the bodies being so arranged that both are amenable to one rack and pinion, the one containing the ground-glass focussing screen, while in the other there is the sensitive plate exposed to the view, all save the protecting shutter, which, when the subject is found to be properly arranged and in focus on the ground glass, instantly flies open and closes again upon "pressing the button," or squeezing the pneumatic ball. This system, however admirable it may be when applied to small or hand cameras, is quite impracticable for those of larger dimensions, say from whole-plate to 12 × 10 and upwards.

In the system now under notice the camera has affixed to it, either at the top or along one side, a pocket telescope, the object-glass of which is of the same focus as the lens of the camera, and it is so adjusted, by means to be presently described, that when taken from the pocket and put in position on the camera it shall, upon racking the camera in or out until a sharp image is seen in the telescope, ensure most infallibly the absolute sharpness of the scene on the sensitive plate in the camera, and the equal certainty of the object visible in the little telescope eventually being found in the centre of the plate when, after exposure, the developer has been applied. The foregoing, in general terms, is the nature of the system; its advantages consist in keeping the object to be taken under constant surveillance from the moment of inserting the dark slide and withdrawing its shutter to the final squeezing of the pneumatic ball.

The object-glass of the telescopic focussing finder should be identical in focus with that of the photographic lens employed. Those whose means are limited will be glad to know that a really high-class telescope is not by any means necessary, as for this purpose we have found one of the cheap foreign ones serve quite well. What is of importance is the identity of its focus with that of the photographic lens. Once this is secured, the rest is easy enough. All that is then required is to attach the end in which the object-glass is contained to the front of the camera and the eyepiece end to the back, having previously taken care to open out one of the jackets in which *any* of the telescope tubes run, in order that, when operating the rack of the camera, the other may slide easily and smoothly without any drag. The details of fixing the telescope are these:—Place the outer end on the camera front at any convenient place, and fix it by any suitable means. It may project beyond the photographic lens or not, this being of no consequence so long as, when fixed, it cannot afterwards be slidden backwards or forwards. We do so by a pin, driven into the woodwork, which projects about a quarter of an inch, and fits into a hole drilled into the main or largest tube of the telescope body. Now focus on the centre of the screen, with the greatest care any object situated within a moderate distance, not one so far away that "everything is in focus." This is done on the ground glass of the camera, and by the camera lens. Next direct the focussing telescope to the same object that was focussed, and, by sliding in or out the still free or eyepiece end, see that this

object is also sharp, and then fix the eye tube to the camera. After this the focussing screen of the camera may be practically discarded, for no further adjustment will again be necessary.

For those who practise photographing of yachts or that of military manœuvres—or, in short, of any of those numerous subjects in which there are objects in motion, and which are constantly changing places, and getting out of focus when a lens with a large working aperture is employed—this system is one that can be very strongly recommended; for, with a plate *in situ*, the eye at the telescope, the right hand at the focussing rack, and the left hand grasping the pressure ball, the subject can be watched and followed until the fitting moment, when a squeeze by the left hand gives the instantaneous exposure.

But it may be said, "This is well enough for a camera having only one lens; how will it apply when one desires to supplant for some special subject the, say, eighteen or twenty-inch focus lens by one of a shorter focus, such as eight, ten, or twelve inches working at equally large or proportionate apertures as the other?" This, too, can be done, but it must form the subject of another article.

LOCAL REDUCTION OF NEGATIVES.

Our remarks on this subject at the close of an article on "Exposure and Density" a fortnight ago have elicited some correspondence to which we take this opportunity of replying generally. One suggestion is made to the effect that local treatment during development, or, in other words, development by means of a brush, is preferable to any after-manipulation; while other correspondents recount their want of success with the methods we mentioned for the latter purpose.

With regard to the first suggestion, we must say without hesitation that we cannot agree with the writer. Valuable as brush development may be, and undoubtedly is, under certain conditions and circumstances, we consider it totally unsuited for the special class of cases to which we alluded. Where a small portion of a negative is found to suffer from under-exposure and to be backward in development or weak in detail, it is admissible to wash off the developer and to reapply it to the defective portion with a brush or other similar means. But where only a small part of the image is fully or over-exposed, and the remainder probably regains the full strength of the developer, as in the case of a feebly lighted interior, the use of the brush becomes in the highest degree inconvenient, if not impossible.

Besides, the use of the brush in this manner requires the greatest judgment and a high degree of skill in order to ensure success, and to apply these adequately in the dim light of the dark room and upon an unfixed negative is to still further handicap the chance of securing a satisfactory result. Where the task before the operator is merely to coax out a little more detail in a shadow, or to strengthen that which already exists, to improve, in fact, a negative the major portion of which is already tolerably satisfactory, it may be undertaken at any rate without the risk of doing any great harm; but under any other conditions it is scarcely possible to hope to achieve any great success.

With the after-treatment, however, the case is altered, for not only is it possible with the fixed negative to judge pretty accurately the amount of modification necessary, but the operator is able to perform the work in a careful and leisurely manner and in a good light; and further, if he be so inclined, he may study the effect produced as the work proceeds by means of trial prints, and so avoid overdoing the treatment.

We strongly suspect that the latter is the rock upon which most of the unsuccessful workers have come to grief, for, unless carefully performed, the process of reduction may end in more harm than good. The effect produced upon the image is, to the eye, comparatively slight after a considerable amount of work, though when it comes to printing—and this is especially the case in the half-shades—the result is not unfrequently startling, showing itself in dark patches or blotches as if the image in places had been almost eaten away. For instance, in dealing with the over-exposed window of an interior which, if very dense from over-exposure or "halation" naturally requires a good deal of working, the tendency generally is to so encroach upon the contiguous portions that, when the window itself is reduced to proper printing strength, it is found in the positive to be surrounded by a dark halo that produces an even worse effect than the original.

The beginner in this style of dodging should always bear in mind the necessity of proceeding slowly and carefully, remembering that, though insufficient treatment at the first attempt can always be supplemented, over-reduction is quite beyond remedy. Therefore the first counsel we would give is to apply only a little work at first, and then very carefully study the effect, or, better still, try a print. In this manner, not only is excessive reduction generally guarded against, but any irregularity or inequality of the work can be detected before it has gone too far. Such irregularity is most likely to occur in such cases as that we have quoted. Where a good deal of work has to be applied to a restricted area, for it is difficult to avoid encroaching upon the surrounding parts more or less, and these will show the reduction proportionately more without requiring it, than the denser portion to which it is desired to confine it. The best means of minimising this danger will be noted in connexion with the different processes as we proceed.

The first plan we shall speak of, because the one most generally employed, though not the oldest in a chronological sense, is one of which Mr. W. Brooks was, if not the introducer, at least one of the earliest exponents. This consists in rubbing down the over-dense portions with alcohol, applied by means of a tuft or pad of cotton-wool or similar material. Some operators prefer to use the bare finger, and, in the case of the fair sex, we dare say the soft skin and delicate touch would answer every purpose; but for ourselves, though not specially "horny-handed," we prefer the artificial rubber.

The first point of importance is the strength of the alcohol, which should be as free from water as possible in order to avoid swelling or softening of the gelatine film, which will inevitably occur if a weak sample be used. Ordinary methylated spirit of fairly good quality is generally of specific gravity about ·827, and this answers quite well, though how the new "mineralised" spirit will behave when applied to this purpose we are unable to say from actual trial. The presence of the small proportion of mineral naphtha is, however, not likely to greatly affect the result. The rectified spirit of the pharmacopœia is too weak to be safely used; therefore, if methylated spirit of the right strength cannot be obtained, it will be better to employ pure alcohol of not higher strength than ·820. Before commencing the reduction it is, of course, absolutely necessary to see that the film is perfectly dry, to ensure which condition it is well to warm the negative, and allow it to cool again just before use.

In applying the spirit, the cotton-wool or other material,

which should also be carefully dried, must be well saturated, but not sufficiently to allow a great quantity of the liquid to flow over the film in rubbing. What is wanted is just sufficient to comfortably lubricate the surface and allow the rubber to move smoothly. When this is attended to, and aqueous moisture is not present, considerable pressure may be applied without danger of injury to the film; but it is preferable not to use too much force, but to proceed gradually. The character of the reduction to be effected will also modify to some extent the method of friction, broad, gentle strokes being required for a wide expanse of sky or general lowering of density, and shorter, sharper strokes where the space to be worked upon is more limited.

The most difficult subjects to treat are portraits, so far at least as the face is concerned, for, if too heavy pressure be applied or too much work done, the deposit will be rendered transparent, and the high lights degraded in the print, a result being produced similar to that obtained by exposing the picture to light after it leaves the printing frame. In cases of harsh contrast in portraiture, it is a good plan to employ an artist's chamois leather stump, though it requires some little practice to handle it successfully. This is useful also in softening the lights of drapery and for similar purposes, though for portraits generally we prefer the process that will be next described, with powdered pumice instead of spirit.

Very often the sky of a landscape negative will show traces of clouds, which are, however, too dense to print out with the landscape unless some means be adopted of shading the latter. In such instances the alcoholic method of reduction answers admirably, the rubber being applied with long, sweeping strokes, following rather closely the sky-line. Where the objects outlined against the sky are distant and softened by atmosphere, it will be the better plan not approach too closely to the line, but to leave a narrow margin of sky untouched, or nearly so, or the outline of sky and landscape may be partially lost. In the case of near objects, cutting the sky-line with considerable contrast, whether trees, buildings, or other objects, the opposite treatment may be followed, the reduction being allowed to extend slightly over the boundary and into the landscape, though not sufficiently to do more than soften the sky-line.

When the desired effect has been obtained, the whole surface of the negative should be flooded with spirit, and gently washed over with a broad camel's-hair brush or loose tuft of cotton-wool, in order to remove the surface traces of the local friction.

An older, and for some purposes a better, method of procedure depends upon the use of finely powdered pumice-stone, cuttle-fish bone, or other abrasive applied to the dry film, instead of alcohol. This plan was introduced to the world some years ago at a meeting of the Photographic Club by Mr. F. Barber, of Sheffield, and caused some surprise by its novelty. Many who tried it at the time failed signally, but probably from two causes—first, want of care in seeing that the film was dry at the time of use; and, secondly, the use of too coarse an abrasive.

For this process it is even more necessary than in the former that the film should be perfectly dry, otherwise it is either badly scratched by the powder or else the latter adheres to it or becomes embedded in it. The same result occurs with films from which the fixing salt has not been thoroughly eliminated; hence, before proceeding to apply the powder process, it is well to soak the negative in water for a few minutes, then gently clean its surface with a tuft of wet cotton-wool and redry it, finishing off with heat to ensure the entire absence of moisture.

Whatever the powder employed may be, it is difficult to obtain it in ordinary commerce in a sufficiently fine state of comminution. The powdered pumice obtainable at the chemists' is too gritty, and utterly unfit for use in its crude state; but, if a small quantity of it be carefully worked in a glass or other mortar for a few minutes, and then sifted through fine muslin, it will assume the form of an almost impalpable powder, without, however, losing its abrasive power. This is the condition in which to use it; and, though on first trial it may seem to produce little or no effect, it will be found on persevering that its action is far greater than at first appears. This should be applied with the bare finger with firm but gentle pressure, the finger being sensitive enough to detect instantly any coarse or gritty particles which might cause damage to the film. The method of application is otherwise much the same as in the case of alcohol, though we think the effect is superior, especially in the case of portraiture and similar delicate work. It has the additional advantage of leaving the surface of the film in an admirable condition for retouching, if that be necessary.

For fine work the chamois leather stump may be used, as in the case of spirit, though it scarcely behaves so efficiently, as the powder seems to bury itself in the leather and lose its cutting power. As a substitute we prefer to use the fine "ink eraser" sold in the form of sticks by Faber & Co. and others. This, if worked to a fine point, answers splendidly on the dry films, being both fine and hard, and very delicate work may be done by its aid.

With regard to chemical methods of reduction, though we have had no practical experience of it for local purposes, we are informed that very good work can be done with the mixed solution of hypo and ferridcyanide of potassium. One method of using it is to thicken the solution with gum or glycerine, and apply it in that state to the parts to be reduced, softening or vignetting the edges by means of the brush. The action requires to be closely watched, and the plate plunged into a vessel of water provided for the purpose the instant the effect is obtained.

Another operator holds the negative in an inclined position in a flat dish containing a very weak solution of the same ingredients, having at the same time by his side a vessel of water into which to dip the plate. Repeated washes of the reducing solution are applied with the brush, alternated with dips into the water until the necessary reduction has taken place. This plan is more especially suited for skies or other broad expanses of subject, but may be combined with the foregoing for general work.

For totally eliminating portions of a picture, or for clearing the skies of transparencies, nothing answers better than a solution of cupric chloride of moderate strength, and thickened with gum or glycerine. This quickly converts the silver image into chloride, and a dip into the fixing bath as rapidly removes it.

THE EXCISE AND METHYLATED SPIRIT.

It will be remembered that, a few months back, we explained the procedure to be gone through in order to obtain methylated spirit of the old kind—that is, free from mineral naphtha—provided the purchaser took as a minimum quantity five gallons at a time. Also that bonds, as security that the spirit

was not used for illegal purposes, were no longer necessary Since then, however, a further concession has been made by the Excise department, so that smaller consumers—such as amateur photographers—may now purchase as little as a gallon at a time. This fact has recently been brought before one of the metropolitan Societies, but it is one of such interest to most workers on a small scale that it should receive greater prominence than is given it in the necessarily brief reports of society meetings.

The form still to be gone through is similar to that given on page 561, *ante*. In the case, say, of the metropolis, a written application is sent to the Excise Department, Inland Revenue, Somerset House, for a licence or permit. In due course, a representative will call on the applicant and learn the purpose for which the spirit is wanted, the probable consumption per annum, where it will be stored, and, presumably, to ascertain that it is not likely to be employed for illicit purposes, &c., also to know the quantity that would be purchased at a time. In a few days, the applicant will be furnished by the Department with the requisite permit and blank forms of "Requisitions for Methylated Spirit." One of these is filled up and forwarded to the nearest methylator, who will then supply the quantity specified. In the case of Mr. Medland, who brought the subject before the London and Provincial Association, this was fixed at one gallon. For all this no charge whatever is made. It must be fully understood that the spirit can only be had direct from a methylator, as the ordinary licensed dealer is not permitted to supply unnaphthalised spirit under any conditions whatever.

It will now be seen that the new regulation as to methylating, which did for a time cause some inconvenience, is now really not such a serious one to experimentalists and small workers as at one time it was thought it would prove. In fact, the authorities evidently are prepared to deal liberally with those who require the spirit for legitimate purposes. This is no more than we suspected would be the case when writing on the subject last year when the fresh regulation was first made. While on the topic, we will say a little more on the subject of methylated spirit.

Most experimentalists are aware that spirit methylated under the new regulation is quite unfitted for several photographic purposes, as, indeed, it is for many others for which the old kind can be employed. Furthermore, alcohol containing even wood naphtha alone cannot be used in some processes, as the presence of the latter would be fatal to the result. In this respect some of our Continental neighbours possess advantages over us, inasmuch as, under certain conditions, they have the privilege of obtaining duty-free spirit without the addition of wood naphtha, but having as a substitute a small proportion of other material.

For many years alcohol was sold duty-free as methylated spirit, provided it contained ten per cent. of wood naphtha. Eventually it was found that such spirit, nauseous as it was rendered by the naphtha, was, diluted with water, being largely used as a potable spirit; also that it was being used as an adulterant of duty-paid spirits, and consequently, it is said, the revenue was thereby being defrauded to a considerable extent. It was this that led to the introduction of the regulation according to which, in addition to the ten per cent. of wood naphtha, three-eighths of one per cent. by volume of mineral naphtha has now to be added. Now, this small proportion of mineral naphtha would not be harmful for most purposes for which the spirit is employed in photography if it were one of the refined variety. But the naphtha has to receive the approval of the Excise authorities, and they insist on the crude article being used, as no other will fulfil the desired end. The same applies to the wood naphtha. That, too, must be approved of by them; and this will not be the case unless it be in a very crude form. So rigid are the authorities on this subject that the methylating always has to be done under the supervision of the exciseman, and the stock of naphthas are kept under his seal.

When methylated spirit was first allowed to be sold, now many years ago, it could be obtained of a much better quality than now. Then, so long as the spirit contained the prescribed proportion of naphtha, the authorities were not so very particular as to the kind used; hence they permitted a somewhat highly rectified pyroxilic spirit to be employed, if desirable. They also allowed a methylated absolute alcohol having a specific gravity of about ·805, containing a somewhat highly rectified naphtha to be sold. As, however, it was soon found that these superior kinds of spirit were being used for purposes for which the authorities never intended—manufacture of tinctures and the like—a fresh regulation was made by which their sale was prohibited.

Reference was made just now to the fact that some countries possess great advantages over England in the matter of methylated spirit—Germany, for example. There the methylated spirit contains but five per cent. of wood naphtha, instead of ten, as the law requires in this country. The use of a more highly rectified naphtha is also permitted. Indeed, we have seen some samples of German methylated spirit that, if it could be obtained here, would doubtless be largely used by unscrupulous persons as an adulterant of potable spirits and other illicit purposes. In Germany also, for some purposes in which wood naphtha would be prejudicial—such as in the manufacture of some coloured varnishes, percussion caps, &c.—spirit is allowed to be sold "methylated" with half per cent. of turpentine and a quarter per cent. of animal oil. Such a spirit would be very advantageous for many purposes if permitted here.

What a Telescope may Do.—From the performances of the Lick Telescope we are able to form some idea of the possibilities of instrumental discovery. This powerful equatorial will not properly divide a double star when the individual stars of the compound subtend an arc of a tenth of a second; hence, to show a star of ° magnitude, an object-glass with a diameter seven times as large as the Lick Telescope would be needed. Further, granted a star of the first magnitude, with a photosphere similar in brightness to our sun, we are told that ten times the Lick diameter would be required.

The New Big Telescope.—Professor G. E. Hale, Director of the Yerkes Observatory of the University of Chicago, has recently published authentic particulars of the new telescope which is to surpass all existing instruments. A decision is shortly to be made, the conditions being that the new telescope is to be the biggest in the world. The learned Professor states that probably from forty to forty-five inches will be the limit of the aperture. At present there exists a pair of forty-inch discs ready made, "but it is not altogether certain that they will be considered large enough by the liberal donor."

Optical Lantern Diagrams.—An excellent method of rapidly drawing diagrams for the lantern consists in using an ordinary blacklead pencil upon a surface, to which is given a tooth by the use of ground glass. A recent invention, however, contains the germ o

an idea, which may eventually prove to give a still better method, by obviating the necessity of frequent sharpening of the pencil. Acting upon a discovery of Major von Sillich, of Meiningen, who found that a pencil made of metallic aluminium gave a legible mark on a slate, a German firm are about to put in the market a pencil made upon the lines thus indicated. They are five millimetres thick and fourteen long, and for the purpose we suggest should, we feel sure, be thoroughly effective.

Changing Big Lenses.—When a camera objective exceeds three or four inches in diameter it is, as every photographer knows, no inconsiderable task to take it from the camera and replace it by another of somewhat similar size. What, then, must the task be when the lens is a yard in diameter, and heavy enough of itself to task the power of several men to lift? We have a very interesting answer to this query from the pen of Professor Barnard, who gives us some details of his experience with the great Californian instrument just referred to. When micrometric work only is in hand, five minutes suffice to prepare this instrument; but, when photography is to be undertaken, ten minutes are needed. This difference is caused by the need of the correcting lens being placed *in situ* to allow for the difference between visual and actinic foci. When the spectroscope is to be used, half an hour is needed to get the prisms in due working order.

"Press the Button" on a Large Scale.—This quotation is so hackneyed as to be familiar in our mouths as household words, but the latest suggestion is on such a gigantic scale as almost to take one's breath away. Already details of the observatory proper that will be needed for the new Chicago telescope are being made public, and foremost in interest to photographers among these are those to which this expression will apply. To return to our camera simile, the difficulty of manipulating those of large size is, as we know, very great, and to scrutinise that portion of image situated at the top of the ground glass is very difficult. With a camera a dozen or two yards long, it is evident that these difficulties would be increased a thousandfold. When "tilting" (for that is the exact equivalent of the "declination"), a ladder is required, and, as this needs moving to follow the stars as they appear to recede, special contrivances, in the shape of "observing chairs," are used. But in the proposed new telescope this difficulty will be oviated: "Press the button," and the whole large floor of the observatory will shift its place, and, with the observer standing at the telescope upon it, move up or down, revolve, &c., till he is brought into the exact position with regard to the instrument that is most convenient to him.

Scientific Principles Applied to Negative Washing.—"Place the negatives under a tap and allow the water to run for some time;" such is the almost universally adopted recommendation. But, as a matter of fact, we have in previous articles shown some of the disadvantages of the process, which is by no means the simple matter that it at first sight appears. Before the Royal Society a paper was recently read which has a very distinct bearing on this subject. The rapidity of flow and other conditions governing the mixing of two liquids when one of them enters the other with some velocity was under consideration. We need not refer to the details of the paper further than to say that one of the liquids was made coloured, in order to show the actual commingling, its extent, and peculiarities. The actual deductions drawn are all that are needed for our instruction, and they were as follows:—"The tendency to instability increases as the velocity of the liquid, the radius of the tube" (in our case the "tap"), "and the coefficient of sliding friction increase, but diminishes as the viscosity increases. The tendency to instability increases as the wave-length of the disturbance increases." This language may perhaps be considered ultra-scientific; but the difficulty disappears when we find that "instability" means practically the tendency of the liquids to mix. It must not be forgotten also that the question of osmose plays an important part in the elimination of soluble salts out of the film.

PHOTOGRAPHING STAINED-GLASS WINDOWS.

For many years the photographing of stained-glass windows was looked upon by glass-stainers and others as an operation which seldom yielded satisfactory results.

The introduction of isochromatic plates, however, has placed in the hands of photographers a new power, and now, with proper arrangements and precautions against halation, very excellent results are obtained.

At the outset, work of this kind requires a considerable amount of forethought. On no account should it be undertaken without first studying well all the troubles and difficulties to be met with—indeed, perhaps there is no class of photography in which it is so necessary to visit beforehand the scene of operations, so as to judge of the various colours to be dealt with and to arrange for numerous other items, as when undertaking stained-glass work; for it very frequently happens that in many cases the windows are in such situations as to render the placing of a camera in a suitable position to copy them a work of the greatest difficulty, and, notwithstanding the benefit of a swing-back to the camera, it frequently happens that special arrangements in the way of rigging up a platform require to be made. In some cases the front of a back or side gallery will be found to lend themselves to the work, but there are instances in which difficulties will be met with that require special arrangements for the standpoint of the camera. Another trouble will be found in the shape of some pulpit or chandelier interrupting the view and so spoiling the design of the window, and in many cases this will be found so aggravated as to be almost insurmountable. In some instances, however, I have overcome the presence of chandeliers by working from a point just at their side, for it is seldom practicable to have them removed just for the occasion. This kind of difficulty often taxes the skill and patience of an operator to a very great extent. In cases where special platforms have to be fitted up, they should be very rigid in their character—nothing in the shape of a makeshift arrangement ought for a moment to be entertained, for when such is employed the attempt will certainly end in failure, if indeed not actual accident or damage to life, limb, or apparatus. Photographers are not chimney-sweeps or steeple-jacks, and, when working on platforms specially erected, they should have the utmost confidence in the stability of the structure; for in this work, if it is worth doing, it is worth doing well. The erection of a suitable platform to work from need not cost an exorbitant sum—such can generally be put together by practical workmen for the occasion in a few hours, and as easily removed.

I have also known cases where more than ordinary difficulties were met with in the way of a chandelier, that the operation of photographing the window had to be delayed until a period of cleansing and renovation came round. When such takes place in a church or other edifice, then comes the photographer's opportunity; at such times, chandeliers are almost sure to be dealt with, and in many instances are taken down for cleaning.

Once in possession, however, of a suitable standpoint to work from, an operator has certainly overcome a great difficulty, and, in a sense, may be said to be master of the situation.

I have said that this work should never be undertaken without a considerable amount of forethought. This is especially necessary in the matter of becoming acquainted with the various colours to be photographed, as well as carefully studying the proper time of day to make the exposure, for in the matter of lighting much will depend in the way of success. Hardly two windows will be found to require the same time of day. As to the selection of diffused or sunlight for the work, I have been forced from experience to decide that sunlight is far and away ahead of diffused light for this work. For interiors, doubtless diffused light is *par excellence* the proper mode of lighting to employ, but the work we are considering must not be classed with interior work: it stands upon a different footing entirely. In nearly all stained-glass windows there will be found portions of deep ruby and orange-coloured glass, and these portions are just about as fine specimens of non-actinic colours as it is possible to acquire. Quite recently I have come across a sample of this ruby, which, to my mind, was very instructive, and I took the opportunity, when photographing the window which contained it, to expose, alongside of an isochromatic plate, an ordinary bromide plate. In the case of the latter, notwithstanding that an exposure of one hour and a half was given with a stop equal to about *f*-32, I failed, on development of the plate, to get any results from this particular specimen of glass. Of course, with the isochromatic plate I employed, the result was quite different, but I was so impressed with the results in this case that I afterwards made a point of specially inquiring from the glass-stainers who erected the window what particular kind of glass this was. I learned it was ruby flashed on a yellow glass. Now, I mention this just with a view of showing how necessary it is to employ

the greatest possible amount of illumination, so as to impress even a colour-sensitive plate. Sunlight in such instances is absolutely necessary. Doubtless there are many other instances in which windows do not contain such non-actinic specimens of glass where a bright diffused light will yield good results, but for cases where such non-actinic colours have to be dealt with diffused light is out of the question.

In selecting sunlight for the work, such time of the day must be selected when the sun is not shining direct into the window, but when such is illuminated by the sun throwing oblique rays upon the glass; this may be from either side. Another precaution very necessary is the selection of such a time as when the sun is not too far to the side, so as to throw any surface light on the inside of the window, or, in other words, the darker the interior of the edifice is the better results will be obtained. A previous inspection of the building when the sun is shining will enable an operator to know to a minute or so just when it clears the front of the window, and when such takes place, in my opinion, that is the best time to expose.

As to the proper plates to use, an intelligent worker nowadays would never dream for a moment of undertaking such work without the aid of colour-sensitive plates. If there are still any sceptics who do not believe in the undoubted advantage of isochromatic over ordinary bromide plates for such work, all I can say is, they have yet something to learn. With the plates I have mentioned I have obtained most excellent results from windows where the predominating colours were from pale yellow down through orange and olive-green to deep ruby, each and all of which are well represented in the negative, and this without the aid of any screen to the lens. Under similar conditions an ordinary bromide plate was absolutely useless.

An operator, who for the first time undertakes this work, say, with the view of exposing a 12 × 10 plate on a fair-sized window, will very likely get a staggerer when he comes to view the image for the first time on his ground glass. If he is at any distance from the window, even with a lens of twenty-two-inch focus, he will feel somewhat disappointed at the smallness of his image; therefore long-focus lenses are frequently a necessity, and should be provided. I have done this kind of work with symmetrical and single lenses, and, notwithstanding all that is urged against the latter being used for architectural subjects, I decidedly prefer to use them at all times, even for this work.

In my opinion another important point is the using of as large a stop as possible when exposing the plate. Some workers may imagine that equally good, if not better results could be obtained by using a very small stop, and giving a proportionately longer exposure, but here we have just a case in point, where the utmost amount of light ought to be conveyed to the plate. My experience clearly shows that the larger the stop the more harmonious the results. Nor is the reason far to seek. When it is considered that we are dealing with non-actinic colours it is at once apparent that to cut off the illumination is wrong in principle. Some of my best results have been obtained with an exposure of about fifteen minutes, whilst with the lens stopped further down, and giving under exactly otherwise similar conditions an exposure of over an hour, I failed to get anything like the same range of tints represented in the negative.

I have often been questioned about the best way to prevent halation. From time to time we hear and read of ingenious devices for preventing this trouble, and quite recently I have had shown to me what some considered wonderful results when photographing interiors—results in which halation was reduced to a minimum by the employment of a new plate, said to be proof against halation; but so long as I can photograph stained-glass windows with the aid of isochromatic plates that yield me colour, correct impressions, and which do not show the faintest sign of halation or dispersion of light, I cannot see the economy of using a plate the cost of which is so far in excess of the other or isochromatic plate.

Without entering into the theory of halation, or what on strictly theoretical grounds ought to be the proper substance in so far as its refractive index, being similar to that of the glass plate is concerned, I may just state that in my practice I am never troubled with halation, and I am certain, were the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY to adopt the good old plan of coating the back of their isochromatic plates (when doing any work likely to show halation) with a cream made by dissolving asphaltum in benzole, we would hear less about this evil.

Whenever it falls to my lot to have to undertake work of the kind I light my pipe and go in search of a common tar barrel, they are not difficult to find in most large towns, and a small lump is always to be had lying about. In a suitable bottle small portions are placed and common benzole poured on till the asphaltum is dissolved, and it assumes the consistency of a thick cream. The night before the plates are required they are subjected to a coating on the back, and then I place over the asphaltum when somewhat set a sheet of brown paper and press this on to the coating of tar. The cells are filled after an hour or two and the plates are ready for exposure.

Some workers have objected to the use of asphaltum on account of it being messy and somewhat difficult to remove *before* development, but with me I never bother about removing it *before* development; I invariably remove it *after* the plate is developed and fixed, and finally washed. The removal never gives me a thought, nor does its presence on the plate during development in any way affect the success or prove injurious. There may be other methods of preventing halation, but I can confidently recommend the one I have described. When used in conjunction with isochromatic plates it is entirely absent.

T. N. ARMSTRONG.

CONTINENTAL NOTES AND NEWS.

Niepce, not Daguerre.—A proposal to erect a new monument to Daguerre in his native village of Brie-sur-Marne has moved M. Leon Vidal, the editor of *Le Moniteur*, to remark that, but for Niepce, there would have been no Daguerre—photographically speaking, of course. Niepce was really the inventor of photography. Daguerre contributed his brick to the edifice, no doubt; but it is often forgotten that, without Niepce, photography would not have been known, and that in that case Daguerre would not have been the inventor of the Daguerreotype. Niepce was the real father of photography. It is an error to suppose also that Daguerre discovered the development of the latent image, inasmuch as a latent image existed in the bitumen process, being developed by dissolution of the unaltered bitumen. Development of the image on silvered copper was a different species of reaction, upon which modern negative processes are based; and, without attempting to minimise the importance of this discovery of Daguerre, M. Vidal concludes by pointing out that he followed Niepce. M. Vidal does service in the cause of historical truth by once more insisting on the relative positions occupied by these two men in the field of photographic discovery. Undoubtedly a great deal of the credit which belongs to Niepce is often given to Daguerre.

Converting Blue Prints into Black Prints.—The *Revue de Chimie Industrielle* says that the prints should be first passed through water acidulated with nitric acid, and thence into—

Carbonate of soda	50 grammes,
Water	1 litre.

In this the picture is changed to an orange tone, when it is removed and placed in—

Gallic acid	50 grammes,
Water	1 litre,

being subsequently washed in water acidulated with HCl.

Recovering Fogged Plates.—In order to render plates which have been accidentally fogged, or have by mistake received two exposures, or are known to have been over-exposed, in a fit condition to be used again, M. Rossignol recommends their immersion in a bath consisting of—

Bromine water	50 c.c.
Tincture of iodine	20 „
Distilled water	1 litre.

After immersion for two or three minutes, the plate is washed and dried. M. Rossignol says that, if the plate has only been partially exposed, it should be exposed to lamplight in order to make the fog impression uniform.

An Intensifier for Gelatine Negatives.—In the *Deutsche Photographen Zeitung*, M. Kirchoff gives the following formula for an intensifier. To a solution consisting of—

Bichloride of mercury	10 grammes,
Water	800 c.c.,

twenty-five grammes of iodide of potassium are added until the red precipitate is dissolved, one gramme of hypo being then introduced. For use, the solution is diluted with its own volume of water, and

intensification is allowed to proceed until the shadows of the negative are of a yellowish-green. The intensification is not apparent until the negative is dry.

Printing on Silk and other Fabrics. — *Apropos* of M Villain's recently published method of photo-dyeing, Mons. A. D. Lavroff writes to the *Paris Photographe*, detailing his method of printing on silk, cotton, &c. He prepares the following mixture:—

Tartaric acid	1 gramme.
Common sugar	10 grammes.
Boiling water	100 c.c.

This is boiled for a minute, and ·5 grammes of borax added, the mixture left for six hours, the clear liquid decanted, 4 grammes of common salt added, and the solution filtered. The fabric is coated with the solution, and when dry is sensitised, dried, printed, toned, &c., as usual.

The Colour of the Sky.—According to a contemporary, M. A. Crova has made a series of researches on the diffusion of light by the sky, and has come to the following conclusions:—The blue colour of the sky reaches its maximum intensity in December, January, March, and the minimum in July, August, and November. The maximum effect appears in the morning, and the minimum at the time of the greatest heat of the day. The intensity of the blue colour is at its maximum in winter, and at its minimum in summer.

THE AMIDOL DEVELOPER.

[American Amateur Photographer.]

A FEW experiments conducted with this new developing agent demonstrates that it is to have an important place in the many developing chemicals now before the public, and to possess some peculiarities that may identify it with the wet-plate developer.

A sample ounce of the chemical was sent to me from England. I found it to resemble somewhat hydroquinone crystals in shape, but darker, similar to the colour of steel. The directions sent with the package explained that it was advisable to dissolve the sodium sulphite first, then the amidol. Accordingly the following proportions were carried out:—

Water	8 ounces.
Sodium sulphite (crystals), Merck's C.P.	800 grains.
Amidol	80 „

The water used was from an artesian well. The above forms the stock solution, and is too powerful ordinarily. It must be diluted by three times its bulk with water. Half an ounce of the above is added to one and a half ounces of water to form a normal developer. When freshly mixed it is colourless, like water, and gradually becomes yellow, and later a dark yellow. The first batch of stock solution that was mixed became milky and turbid after an hour, and in the course of five hours quite a precipitate settled at the bottom of the graduate, which was dried on blotting paper and had the colour of steel. This precipitate did not seem to weaken the developing power of the developer; but it was not what one would expect. I am convinced it must have been due to the water, which probably contained some lime. However, the developer mixed as described was poured over an 11 × 14 sheet of Eastman's slow bromide paper, which had been liberally exposed to daylight behind a cardboard drawing, and to the astonishment of all, developed up in about five seconds to full density. The blacks were of a delicate, velvety colour, while the whites were remarkably clear and free from any sort of veil or stain. Sheet after sheet was rapidly developed in the same solution (eight ounces) until the eighth or ninth, when it began to work slower, and the blacks were not as brilliant. But a dozen good bromide prints of 11 × 14 were obtained with only twenty grains of amidol. It apparently made no difference whether a long or short exposure had been given; the development began as rapidly and acted uniformly on every portion of the film that had been exposed to the light.

Desiring to secure, if possible, a solution that would show no precipitate, a second batch of the stock solution was prepared as above with the exception that distilled water was substituted for the artesian well water. An absolutely colourless solution was the result. There was no precipitate, and after standing in a graduate covered by a sheet of glass for twenty-four hours, the colour became a faint yellow, which became slightly deeper in two or three days. The experiment showed conclusively that rain or distilled water should be used. With six grains of amidol in this distilled water developer, I developed in a short time one dozen 3¼ × 4 films, one after the other (time and shutter exposures), and obtained very clear negatives, even though in some cases the film was in the developer for twenty minutes. I next tried a fresh solution, of similar strength to the foregoing, on two Cramer isochromatic rapid plates, having had quick shutter exposures. After pouring on the developer, the image rapidly appeared in three or four seconds, and in three minutes the negative had reached ample density and was done. A second plate came up nearly as rapid: both were excellent, clear negatives. The solution, after development, was saved. It was clear (with the exception of particles of film that had become detached during development), and was used the next day in developing half a dozen 4 × 5 bromide prints.

The marked difference amidol has over other developing agents, is that it is quite soluble in cold water, can only be used with neutral sodium sulphite, in place of an alkali, and refuses to develop in an alkaline solution. It is distinctly an acid developing agent, and when rightly understood will be a great help in the production of line negatives and lantern slides. To test the developing power of amidol by itself, a solution was made by dissolving twenty grains in four ounces of water. This was poured on by a properly timed plate and kept on for over five minutes. In that time no trace of an image appeared. Next, ten grains of carbonate of potash were added, and the development continued for three or four minutes more, but still no sign of an image appeared. The potash turned the solution from a colourless one to a deep handsome red. Having no sulphite of soda at hand, the experiment was not carried further.

At another time a separate solution of chemically pure neutral sodium sulphite in distilled water was made (strength 100 grains to the ounce), also a separate solution of amidol (twenty grains to two ounce of distilled water, equivalent to ten grains to the ounce). One-half of the amidol was taken (one ounce), to which was added half an ounce of distilled water. The ounce and a half pure amidol developer was then poured over a shutter-exposed isochromatic plate; after five minutes no trace of an image appeared. Testing the solution with blue litmus paper showed that it was acid. Next the experiment of adding to this apparently inert developer, a drachm at a time, and by half drachms, the sodium sulphite solution mentioned above was undertaken. First a drachm was added after three minutes; there was no sign of an image. Then two half-drachms went in; soon the image began to appear—developed out slowly, similar to plates in eikonogen weak in an alkali. The negative had good density and was finished in six or eight minutes. The solution was now tested with blue litmus paper, and showed an acid reaction, though not as strong as before the sulphite was added. Thus it was found that twenty-five grains of sodium sulphite to seven grains of amidol are necessary to set up a developing action, and that the addition of so much more (100 grains of sulphite to ten of amidol, as given in the formula) accounts for the rapidity with which a slightly diluted solution of that kind acts. The sodium sulphite may be regarded as the accelerator in the admidol developer—the same as the alkali carbonate of potash or ammonia is in the eiko or pyro developer. With the ounce and three-quarters of solution five 4 × 5 and two lantern slide-plates were developed, all being of extreme brilliancy and clearness; the high lights of the slides were clear glass. The colour of the developer was light yellow. On testing the standard solution (100 grains of sulphite to ten of amidol) with blue litmus paper there was apparently no change, showing, we think, that it requires that amount of sulphite to counterbalance the acidity of the amidol.

The other portion of the plain amidol solution changed very soon—in three-quarters of an hour—from being colourless to a deep red, but kept clear. At this writing it has not been tested as to its developing power when compared with a fresh solution, but it is likely that it will be as effective.

Amidol is very nearly as soluble in distilled water as pyro; hence it may be advisable to keep it in its crystal state until ready to use, then to mix up a small quantity and add gradually enough sodium sulphite (which may be kept in a stock solution) to produce a developing action. By varying the proportions of two, rapidity of development is to be regulated as well as the density of the image, while the tendency of the developer to veil the unacted upon portions of the film during prolonged development, is reduced to a minimum, and whether over-timed or under-timed, plates will come out always clear and brilliant. No bromide need be added if the proportion of sodium sulphite is lessened.

It will seem strange to many to consider sulphite as an accelerator in this developer, when heretofore it has been regarded as a retarder;

but when its action has been so clearly demonstrated, as outlined in the foregoing described experiments, there is no doubt about its function. Besides being an accelerator, it also serves to retard the supposed oxidation of the amidol.

The addition of sulphurous acid would probably be beneficial, as it would aid in preserving the developer, when standing, from oxidisation and keep it clear for a long time. The use of acid sulphites, it seems, is also allowable. The description in the patent curiously confirms the experiments I have mentioned as to the accelerating action of the sodium sulphite, and it may be possible by different modifications or additions to secure different colours or tones to negatives or positives.

F. C. Beach.

THE SIZE OF STOP TO USE.

[American Journal of Photography.]

So much has been written about "sharpness *versus* softness," and the like, that some apology is necessary for even referring to the subject again, and I should not do so but that, having expressed pretty decided views on the subject some three years or so ago, and having, after continual study of the subject since, had reason to modify these views considerably, I wish to have an opportunity of restating my opinion.

The views that I expressed when I wrote last on the subject were briefly that, in the case of a landscape, the principal object ought to be sharp, or nearly so, according to the taste of the artist, all reasoning tending to show that it ought to be as sharp as the best optical instruments could make it, but that objects nearer to or farther from the camera than this ought to be less sharp. My reasoning was that as, if in nature we look on what is the principal object of the landscape, objects nearer or farther look "out of focus," we ought to try to reproduce this effect in the negative.

Sharpness of the Principal Object.

In the first place as to the sharpness of the principal object. I am more inclined than ever to think that, in most cases at least, this ought to be as sharp as it can be made in the negative. I say in the negative, because I admit that a charming effect is produced by the softening or slight loss of definition that results from reproducing from a negative by certain processes. Thus, to me, the softness that there is in most pictures produced by intaglio copperplate photo-engraving is a totally different thing from the effect got by printing in silver, even on matt-surface paper or in platinotype, from an ill-defined negative. The one effect is beautiful, the other, generally at least, is not. It seems to me that those whose taste leads them to avoid absolute sharpness in any part of a picture would find it best to get the softness they want in the after-process of printing rather than in the negative. Mr. George Davison has described various ways of producing such softness from a negative in which the definition is quite sharp.

Even if it is decided to get softness or slight want of definition in all planes of a negative, it is to be borne in mind that this softness may differ in quality. Thus the softness got by admitting an appreciable quantity of spherical aberration is quite different from that got by putting the whole of the picture a little out of focus. The softness got by admitting a little spherical aberration is of a much more pleasing kind than that got by putting the image out of focus. The reason is that, in the former case the image may be said to consist of one of perfect definition; in the latter case there is nothing but lack of definition. It is for this reason that I have often stated that an optical *desideratum* is a landscape lens with an adjustment, whereby a *large quantity* of spherical aberration can be introduced at will, so that what softness is wanted may be introduced even when a small stop has to be used on account of nearness of foreground objects.

The Doctrine does not Hold Good.

Now, as to making the principal object the sharpest (strictly speaking, the most nearly sharp) in the picture, whether or not it be made absolutely sharp, I am afraid this is a doctrine that does not hold good. In the first place, many pictures have no principal object, or no object of which it can be said with any degree of confidence that it is the principal object. Much more important, however, is the following fact: If there be any object in the foreground, the least conspicuous, even if it is not an object of particular interest, and if any more distant object be made sharper than this, the effect is distinctly bad. In other words, it is necessary to focus for the nearest object that is in the least conspicuous, apart from whether it be the principal object or not, and it very seldom is the principal object.

Should the Distance be Out of Focus?

Now as to whether the rest of the view should be put distinctly out of focus or not. There can be only one object in putting the more distant parts of the landscape out of focus, and that is, to give an impression of distance, the thing in which photography most commonly fails. The question is, Does this leaving out of focus give the impression of distance, or does it not? I have no hesitation in answering that there are cases where it does, and that there are cases where it does not, but where the only effect of leaving the distance out of focus is a totally unnatural one. If this be granted, the natural question is, In what cases is it of advantage to leave the distance out of focus, in what cases should it be sharply focussed? To this, I am sorry to say, I can give no answer farther than that continual observation and experiment will educate the eye to be able to tell whether or not the idea of distance will or will not, in a particular case, be given by the use of a large stop. By experiment I mean the taking of two or more negatives of the same subject with stops of different sizes, no adjustment of focus being made between the exposures, and comparing the resulting pictures. This is a thing I strongly advise to those who wish to study this matter, which is of the utmost importance to landscape photographers. It may be asked, Why take negatives? the effect can be seen on the ground glass. There may be some gifted enough to tell exactly what the print from a negative will look like by examining the image on the ground glass, but I think they are very few. The difficulty arises from the want of light, except when a very large stop is used, and from the fact that it is all but impossible, as a rule, to see the image on the ground glass as a whole.

There is one thing I incline to state, although with some diffidence. It is that, when the impression of distance is really rendered in any other way, as by the correct representation of atmospheric haze, there is no necessity to add an out-of-focus effect, and it is generally a mistake to do so.

Different Planes in Relation to Focus.

There is another difficulty about leaving the distance out of focus. We have not the power of controlling to what extent the different planes shall be out of focus. The relative want of sharpness is purely a function of the distance. Thus, suppose we have a well-marked foreground, an object at a considerably greater distance that is distinctly the "principal object," and a "distance." The foreground, as has been stated above, must be made at least as sharp as any other part of the picture. The principal object may, perhaps, be made a little less sharp, but that is all. It may be desirable in this case to leave the distance quite appreciably out of focus, but this is generally impossible. If the "principal object" be several times farther away than the foreground, and the latter be focussed for, there will be no appreciable difference in sharpness between the principal object and the distance. There are some cases where the difficulty may be got over by focussing for a plane between the foreground and the principal object, but they are exceptional.

The Foreground.

Talking of foreground induces me to express the opinion that very few photographers seem to appreciate the importance of foreground—or perhaps they are debarred from making the best use of foreground by the extreme difficulty of treating it. I mean here, foreground quite close to the camera. We have only to look at the work of any good landscape painter to see what a power there is in foreground at quite a short distance—what an amount of relief it is capable of giving to a picture. Such foreground does not need to consist of important objects. A stem or a branch of tree, a bit of a road, a few agricultural implements, or a little foliage will do.

There are several difficulties in the case of rendering such foregrounds by photography. One is that of focus. This is especially felt in the case of large work, and where long-focus lenses are used. There is a certain class of photographer that is continually laughing at the *f*-32 man. Of course, a man who makes a habit of using *f*-32, or any particular stop, in all cases, deserves to be laughed at; but, if due attention be paid to foreground, I have no hesitation in saying that it is often necessary to use a stop much less than *f*-32 to get the foreground and the rest of the picture even fairly into focus. This brings another difficulty, namely, prolonged exposure, and, as the most appropriate foregrounds for the work under discussion very often consist of foliage, which is very seldom still, the difficulty becomes serious. There is still one difficulty more, and that arises from the tendency that photography has to render such near foregrounds as I have been writing of too dark. This can often be got over by appropriate selection, in other cases by skilful manipulation of the lens cap. Only in some stereoscopic work, done at the time that the stereoscope was so much used that the masters of landscape photography produced pictures of it, have I seen foregrounds treated as I here describe.

Breadth of Effect and Suppression of Detail.

It seems to me that many of those who have no part of a photograph sharp fall into a certain error. They state that the defect of ordinary photographs is the want of "breadth." There is no doubt they are right here, but they seem to go farther. They appear to think that if definition be suppressed by having no part of a picture in sharp focus, breadth will result. But will it? In the first place, is "breadth of effect" obtained by artists by suppressing detail? To a certain extent it is, but I think it is effected more by emphasising salient points. But, even so far as the detail goes, I cannot see that leaving the picture out of focus suppresses this detail. It only confuses it, and, in some cases at least, makes it more conspicuous than it otherwise would be.

How to get "breadth of effect" is certainly the great problem for photographers. Beyond selection of subject and occasional manipulation of the exposure, so that one part of the subject gets more than another, I can see nothing to be done but to "dodge" the negative in printing, sometimes by shading one part of it for part of the exposure, sometimes by working with pencil and stump on tissue paper stretched on the back of it. And I believe the purists, who are just those who most recognise the lack of "breadth" in photographs, consider this practice illegitimate.

However this may be, I wish to impress on landscape photographers that the very highest judgment can be exercised in deciding (1) what plane of a subject shall be focussed for, (2) what stop shall be used. Indeed, the differences of effect that can be produced by varying these two factors alone are so great, that it ought, I think, to entitle photography to rank as a high art.

W. K. Burton.

ON THE METHOD OF EXAMINATION OF PHOTOGRAPHIC LENSES AT THE KEW OBSERVATORY.*

17. *Illumination of the Field. The figures indicate the relative intensity at different parts of the plate.*

With C.I. Stop No. .		With C.I. Stop No. .
At the centre 100	: Ditto	100
At inches from the centre	: Ditto	
At inches from the centre	: Ditto	

The intensity of illumination of the field is always greatest near the axis of the lens, and falls off more or less rapidly towards the edges of the plate. The lens should therefore be examined with the view of ascertaining if this inequality of illumination is greater than that which experience shows must be tolerated under given circumstances. The apparatus employed for conducting this test is shown in Fig. 23, the method being devised by Captain Abney. There is a fixed lamp, L, the

Fig. 23.

position of which is not changed during the observations; F represents a paper screen, placed in that position in order to give a practically uniform source of light: O is the lens, which is fixed in a frame, not shown in the sketch, revolving upon the pivot N; by means of a suitable adjustment this axis, N, is made to pass through the nodal point of emergence of the lens. At S there is a sheet of cardboard with a small hole in the centre at H, and this screen, hole and all, is covered with thin white paper on the side away from the lens; the distance between H and N is always made equal to the principal focal length of the lens; the bar D is made to cast a shadow from the movable lamp M on the paper just over the hole in the cardboard; thus, in this shadow, the paper is illuminated entirely by transmitted light from the lens, whilst the paper round it is illuminated entirely by the light of the movable lamp.

An observation is made in the following manner:—The lens is first placed in such a position that its axis passes through the hole H; the lamp M is then moved backwards or forwards until the transmitted illumination of the paper at H is made to match as nearly as possible the reflected illumination of the paper round it; the distance between S and M is then noted. The lens is now placed in the position shown in fig. 23, where AB represents the length of the diagonal of the plate for which the lens is being examined, and where the angle ϕ is half the angle of the field under examination. The balance of light is readjusted by a movement of the lamp, and the distance MS is read off a second time. By finding the inverse ratio of the square of these two readings, we thus obtain the ratio between the illuminations at P and H, the lens being in the position shown in the sketch, and the object being supposed to be equally illuminated in both cases. But what is wanted is the ratio between the illumination on the plate at P and A; this is found with perfect accuracy by multiplying the ratio of the illumination at P and H, as above obtained from the observations, by $\cos^3 \phi$, and this result is that which is entered in the Certificate of Examination. The relative illumination of the centre and of any part of the field can, of course, be obtained in this manner, in the above instance the corner of the plate being the point chosen.

This test may with advantage be made with the largest stop supplied, and also with the stop which has been shown, under test No. 13, to give good definition over the whole plate.

It cannot, however, be denied that there are objections to this method of examination. The fact that the illumination of the plate is not uniform is due to several causes:—(1) The amount of light which passes through any aperture evidently diminishes with the obliquity. (2) With lenses not free from distortion, the effective aperture itself varies with the angle of incidence. (3) The amount of reflection from the surfaces of the lenses, and consequently the amount of transmitted light, varies with the angle of incidence. The method of observation above described may be said to fully take into account these three causes of variability in intensity. Then again (4) the light falling on the plate varies inversely as the square of its distance from the nodal point, and also (5) with the obliquity with which the rays strike the plate. As far as these two latter considerations alone are concerned, it is evident, therefore, that the illumination on the plate varies as the third power of the angle incidence, and also that by multiplying the result obtained on the screen at H by $\cos^3 \phi$ we obtain the required result on the plate at A. Thus the record in the certificate includes all these first five causes of irregularity of illumination. But there are other causes which are not correctly represented in this method of examination. In lenses not free from distortion the nodal point of emergence varies in position with the angle of incidence, and, as the pivot N does not shift its position with reference to the objective during the observation, the condition of illumination of the photographic plate cannot be accurately represented. This is probably a trifling cause of inaccuracy, but one somewhat serious source of error remains to be mentioned. The method of examination does allow for (6) the variation of illumination due to the different amount of glass through which the oblique pencils have to travel; but, as the observation is made by eye, no allowance can be made for the fact (7) that the actinic rays may be affected in this manner out of all proportion to the apparent variations produced in the visible rays.

The method of examination adopted at Kew assumes that the light transmitted through the paper, as well as that reflected from the paper, varies in amount with the intensity of the incident light Captain Abney informs me that his experiments prove this to be the case. But in making the observation the eye should be placed in the same position during both readings; for we have no reason to suppose the transmitted and reflected lights vary in the same way with the angle of vision.

It is impossible to suppose that the screen F will be illuminated with perfect regularity, even near its centre, and this must be a source of error, though probably a negligible one. When the axis of the lens passes through H the rays which are brought to a focus at that point will be parallel to each other as they enter the lens; but when the axis of the lens is inclined this cannot be the case, for H will no longer be on the principal focal surface; the screen F should therefore be brought as near the lens as possible, as by that means the part of the screen from which the light comes will be more nearly identical in the two cases. The lamp L should, moreover, be placed as far from the screen as practicable, so as to make the illumination as uniform as possible. With lenses in which the nodal points are some distance apart, the part of the screen from

concluded from page 795.

which the light comes will vary considerably with the inclination of the axis, and considerable errors might be introduced by uneven illumination of the screen.

In deciding on the quality of a lens as regards the illumination of the field, this test should be considered in connexion with test No. 10, under which heading are given the angles of the cones of illumination. With regard to the normal use of any lens, except perhaps such as are specially designed for portraiture, certainly the whole of the smallest stop, and, as a rule, the whole of the largest normal stop, should be visible from the whole of the plate; for if the plate extends much beyond the limits of the inner cone (outside which the aperture begins to be eclipsed), the falling off of density near the edges of the plate will be a serious defect in the photograph. When considering the part of the field lying within this inner cone, it is to be noted that, the wider the angle which the lens covers, the greater is the inconvenience caused by the diminished density near the margin; if the stop is in front of or behind all the lenses, the intensity of illumination of different parts of the plate can be shown in this case to vary approximately as the fourth power of the cosine of the angular distance from the axis of the lens, and in cases where the stop is between two lenses, the limits of variation will be the third and fourth powers of the cosine of the angle. The following table is therefore inserted to give an approximate idea of the decrease of illumination as we recede from the axis of the objective, the truth lying *theoretically* somewhere between the two limits here given:—

ϕ.	$\cos^3\phi$.	$\cos^4\phi$.
0°	1·00	1·00
5	0·99	0·98
10	0·96	0·94
15	0·90	0·87
20	0·83	0·78
25	0·74	0·67
30	0·65	0·56
35	0·55	0·45
40	0·45	0·35
45	0·35	0·25

Eminent lens-makers have spoken of the illumination produced by their lenses as being uniform from the centre to the margin, but our experience is that the decrease is even more rapid than here indicated. The above table shows how very objectionable is the use of wide-angle lenses, whenever they can possibly be avoided. It shows, moreover, that the theoretical exposure for different stops should be materially modified according to the angle which the lens covers; for intance, taking the last column to represent the truth, it would be right, even though the stops in the two cases had the same C.I. number, to give half as much exposure again with a 90° objective as with one only covering 40°, in order to get the same mean exposure over the whole plate.

In connexion with this test, it may be mentioned that the most serious omission in the Kew examination is, that there is nothing to show the actinic transparency of the glass. A slight yellow tinge in the lenses, which would not be noticed by the eye, might yet be sufficient to seriously affect the rapidity of the objective. But no test could be devised to investigate this point which did not introduce photographic methods, and, as already stated, the consideration of expense put such operations out of consideration for the present. I should like, if possible, to have introduced some test which would have at the same time indicated the actual rapidity of the lens, and also the actual falling off of density towards the margin of the photograph; with the aid of photography this would not have been difficult, and a plan of this kind would have been adopted, but for the cost. This subject is, however, still under consideration by Captain Abney.

LEONARD DARWIN, Major R.E.

MR. A. R. DRESSER ON "ENLARGING."

BEFORE the Blackheath Camera Club, on November 29, Mr. A. R. Dresser gave a lecture on *Enlarging*, in the course of which he said that enlarged prints might be obtained from small negatives either by putting the negative in the camera and projecting the image through the camera and lens on to a sheet of bromide paper, or by fixing the negative in the window and taking a positive from it on paper in a large camera, this being the method he used himself and recommended as being productive of the best results. All his own enlargements were made by daylight, as he considered this more satisfactory than any artificial illuminant, the success of an enlargement depending greatly upon the brilliancy of the light. He explained that stopping down the lens does not increase the definition for enlarging purposes, though it may sometimes appear to do so. When a stop is used, the exposure is diminished, and, therefore, the print, when developed, may have greater contrasts than one given the same exposure with full aperture, thus giving an effect which sometimes is mistaken for sharper definition.

With regard to exposure, to enlarge from a quarter-plate negative of fair density up to 12 × 10 on an ordinary fine day, with stop *f*-16, he would give from three to four minutes' exposure, or with a thin negative, about two minutes. He considered iron to be the best developer for bromide paper, although, as he generally toned his prints with uranium, he had given up using it, on account of the difficulty of completely eliminating the iron from the print. The slightest trace of iron will cause blue stains in the toning.

The developers he recommended were eikonogen and amidol, and he gave the following formulæ:—

Eikonogen Developer.

Eikonogen	1 ounce.
Soda sulphite	4 ounces.
Potass. carb.	1 ounce.
Soda carb.	1½ ounces.
Water	30 ,,

No bromide being necessary. It is advisable to dilute this developer with half water until you become accustomed to its action.

Amidol Developer.

A.

Amidol	1 ounce.
Potassium metabisulphite	1 ,,
Water	10 ounces.

B, a saturated solution of either washing soda or potassium carbonate; C, a ten per cent. solution of potassium bromide.

For use take A, 1 drachm; B, 1 drachm; C, 5 drops; and water, 1 ounce.

Prints should not be cleared until after fixing, to avoid carrying any acid into the hypo bath.

When very rough paper is used it should be well soaked in water before developing, but this paper should only be used for suitable subjects.

If the print appears to come up too rapidly, from over-exposure, pour off the developer, and turn print upside down in a dish of water and leave it to develop by itself; it will rapidly gain density without fogging.

In the case of a negative in which any portions are either weak or over dense, it is better to try to counteract these deficiencies by dodging during the exposure than by trusting to local development or reduction.

THE OPTICAL LANTERN AND HOW TO USE IT.

THE Rev. W. H. K. Soames gave a discourse on this subject on December 8 before the Blackheath Camera Club.

In speaking of the source of light, the lecturer explained the advantages of the mixed jet over the blow-through jet. The jet being nearer the lime, and giving a smaller point of light, better definition is obtained. There is no flame, and very little heat from it, and it uses considerably less hydrogen. With the blow-through jet coal gas can be used, but hydrogen gives a better light when it can be obtained.

When using these gases, the bottle valves must be turned on full, and the governors allowed to take the pressure. The supply being regulated by the valves to the jets, care must be taken to see that these valves are closed before turning on the gas at the bottles.

He pointed out that when a short-focus objective is changed for one of long focus, the condenser must also be changed to get a good result. To explain this, he showed the different effects and sizes of discs produced with different lenses.

In lighting the lantern the hydrogen must be turned on and lighted first, and then the oxygen turned on slowly, and both gases regulated until a perfect light is obtained. The lime should be turned every two or three minutes, or else with the mixed jet the flame will double back from the small pit formed in the lime and crack the condenser; it will not do this with the blow-through jet, but the flame from the hydrogen may fork out and set fire to the lantern. With short-focus lenses the light must be nearer the condenser than for long-focus lenses; but with either lens, if it is too near, a dark mark will appear on the disc; the light should be moved laterally or vertically until this mark is exactly central, and then drawn back from the condenser until the mark entirely disappears.

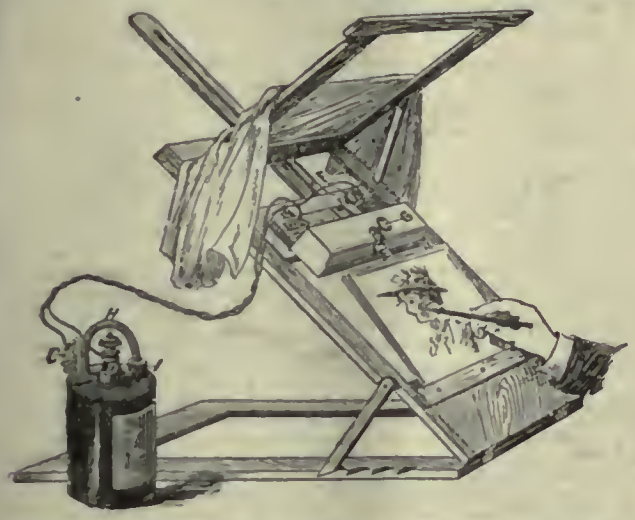
After the lecture a number of slides were shown, the disc being thrown upon a blue distempered wall with excellent effect.

RETOUCHING BY ELECTRICITY.

WE have already alluded to an electric retouching apparatus of German inception and manufacture, which is now being employed in America and on the Continent, and a considerable degree of interest has been manifested in this country as to its nature and probable value in retouching.

By the kindness of Mr. C. A. Rudowsky, 3 Guildhall-chambers, E.C., we have been permitted to examine one which he has just imported in

order to have its value tested by expert retouchers in this country. The pencil is held in the hand, and is manipulated in the usual way; but the negative, when placed on the easel with the upper end resting upon a

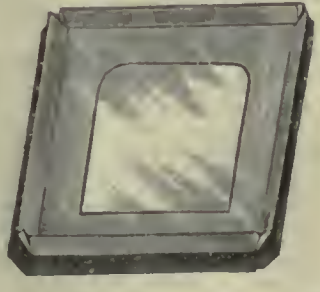


padded ledge of the apparatus, is subjected to a series of rapid vibrations by which what would otherwise be an unbroken pencil line is now interpreted by a stipple of greater or less granularity, the coarseness of the stipple being determined by the adjustment of a screw. The cut shows the apparatus adapted to an ordinary retouching desk.

It is claimed that the smoothing of the skin is most easily accomplished, and even larger spaces, which in ordinary circumstances have to be covered from the back, are easily and quickly retouched with this apparatus; and that it is a great improvement upon any electric retouching apparatus that has been introduced before, as the retoucher here is not influenced by the current, and only the negative vibrates. Using an apparatus three or four hours a day, one current is sufficient for more than a year; while two currents, which are used alternately, will last years. With large plates two currents combined are used. The price is certainly reasonable enough, being only 36s.

A COMBINED LANTERN MASK AND BINDER.

The Blackfriars Photographic Company, of Surrey-row, are introducing a combined lantern mask and binder, which should greatly facilitate the mounting of lantern slides, and be convenient in other respects.



In effect, it consists of a couple of masks joined together, the edges being left free and coated with mucilage. All then that remains to do is to place the slide and cover glass in position as usual, and secure them by moistening and pasting down the gummed edges. The idea is a happy one, and reduces the trouble of mounting slides to the minimum. The usual variety in the shapes of the mask openings are available.

FERROTYPE PORTRAITURE BY FLASHLIGHT.

Mr. L. Nievsky has recently been demonstrating, with great success, a simple method of taking portraits at night on ferrotype gelatine plates. The system is semi-automatic, being, we believe, analogous to, if not identical with, that laid under contribution during the last summer for daylight portraiture. Briefly described, the apparatus is as follows:—Forty ferrotypes, in sheaths, are held in a receptacle placed on top of the camera, and when the sitter is focussed a lever adjustment places one plate in position, the exposure is made by means of a flashlight, and by two simple movements the plate is conveyed to the developing tank, where it is subjected to the action of the developer, fixer, and wash water actuated by three separate pneumatic balls.

The exposure required at night is about two seconds with six to eight grains of magnesium blown through a spirit flame. A strong hydroquinone developer is used, the rapidity of its action depending on the temperature. At this time of the year, in an ordinary room, less than a minute suffices to develop a picture. The presence of a small quantity of hypo in the developer acts, according to Mr. Nievsky, as a restrainer, the developer required being a very powerful one for such quick work, and a much brighter image being obtained by the mixture. Some sixty or seventy plates (size about $1\frac{1}{2} \times 1\frac{1}{2}$) are developed in one solution.

We have been present on two occasions when Mr. Nievsky has taken the portraits of members of societies with the Simplex (as it is called), and can speak as to the nature of the results, which, of the kind, are excellent. The portraits are delivered washed, dried, and mounted in two or three minutes.

THE "HOLBORN" HINGED-SPRING PRINTING FRAME.

Messrs. Geo. Houghton & Son (89, High Holborn, W.C.) have sent us a sample of a printing frame they are making, the peculiarity of which

lies in the springs by which pressure is produced. These are so bent that each one bears in two places on the pressure board, and is hinged at one end so as to fold over directly upon the pressure board, the loose end then being fastened in a simple manner, as shown in the cut.

A THOUSAND CANDLE-POWER ILLUMINATOR.

As an aid to the feeble daylight prevailing in winter, magnesium may be employed with excellent effect in obtaining portraits. But flash-lamps, although exceedingly useful in numerous cases, are not well adapted for an exposure of several seconds during a dull day. We have seen good

effects in lighting obtained by reversing, in a sense, the usual conditions under which the sitter is illuminated, employing the daylight to lighten the shadow side, the predominating light being obtained by magnesium; and while there is any daylight at all worthy of the name, the sitter will not be disturbed by the artificial light.

To aid in this *desideratum*, Messrs. Perken, Son, & Rayment have introduced a continuous photo-exposure illuminator, shown in the cut, in which magnesium powder, blown through a spirit flame, causes a continuity of light that is highly actinic. The large rubber reservoir by which the pressure is maintained is kept inflated by the smaller one. The reservoir is of such dimensions as to contain a considerable quantity of magnesium. It is claimed that this illuminator possesses features of difference from other magnesium lamps of the continuous order.

Our Editorial Table.

The American Annual of Photography.

We are favoured by Mr. Jonathan Fallowfield with a copy of this well-known annual issued by the Scovill & Adams Company, New York. Got up in the style for which this annual has acquired a high reputation, with its good paper and bold typography, it is further enriched by several nicely executed process-block illustrations. The contributed articles are of the usual variegated character, and embrace the topics of current interest. Mr. C. W. Canfield continues from a former issue his interesting notes on the portraits of Daguerre. Mr. Jerome Harrison describes a camera called the "Henry Clay," made by the Scovill & Adams Company. M. Duchochois condemns simultaneous toning and fixing; the Rev. G. M. Searle contributes a suggestive article on taking stereoscopic negatives with the aid of a prism; Dr. Clarence C. Woodman an equally excellent one on "Detective Camera Focussing." These together with many others make an excellent book of photographic reading matter. We may, perhaps, be permitted to take exception to an article by G. C. Rhoderick, jun., in which he recommends the making of "stereoscopic" views by mounting side by side two identically similar prints obtained from the same negative. This writer seems to forget that to produce a stereoscopic picture two *dissimilar* views of the subject must be employed. Despite this there is so much that is sound and good in the *Annual* that it may be well passed over. The work sells at 2*s*. in paper covers, and 4*s*. bound.

An Improvement in the Manufacture of Sensitive Plates for Photographic Purposes.

No. 21,381. John Tyack Sandell, 10, Pall Mall, London, S.W.—*November* 19, 1892.

My invention relates to an improvement in the manufacture of sensitive gelatine plates for photographic negatives, and it has for its object to diminish the liability to halation and solarisation (or reversal of the image) which are incidental to photographic plates as now made when subjected to a comparatively slight excess of exposure.

By employing plates made according to my invention, it is possible to produce photographs in which all the details of subjects presenting strong contrasts of light and shade are perfectly brought out. For example, the interiors of churches and the like, where the windows and other apertures are illuminated by a strong external light, are exceedingly prone to halation and solarisation of those brilliantly illuminated portions, coupled with insufficient exposure of the less strongly illuminated parts of the subject; but by my invention these defects are avoided, as a much greater latitude in the duration of exposure is admissible without injury to the resulting negative, by reason of the fact that, owing to the compound structure and differential sensibility of the improved plate, what would be over-exposure in the case of an ordinary plate of similar rapidity is compensated, as hereafter described.

My invention consists in coating the plate, substantially as hereinafter set forth, with two or more superposed coatings or layers of gelatine emulsion, having different degrees of sensibility to actinic light, so that different portions of the picture which are in strong contrast as regards strength of illumination will be photographed virtually upon layers or strata of different degrees of sensitiveness, the effect produced upon the haloid silver salt or salts of the less sensitive stratum thus compensating for the deficiency of intensity due to over-exposure of the corresponding portion of the more sensitive stratum. The coating which is first applied to the plate, and which constitutes the underneath or rearmost stratum, should possess the least degree of sensitiveness, and the front or uppermost one should possess this quality in the highest degree, the intermediate layer or layers (in the case of more than two) progressing in regular gradation between the two extreme degrees of sensitiveness. The prevention of halation is due to the greater opacity and lesser sensibility of the lowermost stratum, which has the effect of absorbing, and so obstructing the transmission of the most powerful rays of light to, and their reflection from, the surface of the support upon which the layer is applied.

The gelatine emulsions composing the different layers or strata would contain any of the usual haloid salts of silver commonly employed. For instance, the first or underneath coating or stratum may be composed of an ordinary bromide of silver emulsion, the next may also be of bromide, or it may be of bromo-iodide, or chloro-bromo-iodide of silver emulsion, or all the coatings may be composed of an emulsion of the same haloid salt, but in any case the second and subsequent coatings will be of progressively increasing degrees of sensitiveness, such difference of sensitiveness being obtained in the preliminary preparation of the emulsion by subjecting it to heat, or treating it with alkali in the ordinary way of treating emulsions for the purpose of increasing their sensitiveness to light. Similarly, as regards the third and subsequent coatings (that is to say, if more than two are used), they would be of successively greater degrees of sensitiveness produced in the same manner by heating or treating with alkali. Generally, two coatings would afford strata of sufficiently different degrees of sensitiveness to meet the ordinary requirements of any kind of landscape work, whilst three coatings are preferable for the majority of interiors.

It is, of course, to be understood that each coating is to be allowed to thoroughly set and dry before another is applied.

In order to ensure the most satisfactory results in working this process, it is essential that the different strata, although varying in sensitiveness to light, should be perfectly uniform in respect to the quality of hardness, and the consequent liability to shrinkage in drying. To attain this essential uniformity, it is important to observe that the gelatine from which the different emulsions are prepared should be of the same make and quality; the different emulsions should be prepared as nearly as possible at the same time; should be subjected to similar and contemporaneous treatment during "ripening," and should be hardened to equal extents by the addition of alum or chrome alum in the usual way, so that (save in respect of the differences in preliminary treatment by cooking, or with alkali, upon which their respective sensitiveness to light depends), the different emulsions to be superposed will be as nearly as possible alike in their purely physical qualities.

In the manufacture of a doubly coated plate for general purposes, I prefer for the undermost layer, or that next the glass, an emulsion prepared by the boiling method, of great fineness of grain, which is more amenable to development than the more sensitive upper coating. The sensitiveness of this undermost film should be about from fifteen to eighteen on what is known as Warnerke's sensitometer, and the percentage composition of the dried film, as calculated from the formula adopted, is—

Gelatine	68·3 parts.
Bromide of silver	29·33 ,,
Iodide of silver	1·1 ,,
Bromide of potassium	·27 part.
Chrome alum	1 ,,

and these quantities in ounces would represent the solid matter contained in 770 ounces of fluid emulsion made up to that quantity with alcohol, thirty fluid ounces, and water.

The emulsion for the upper layer consists, preferably, of a mixture of one

part of a boiled emulsion made by means of the centrifugal separator which is found to have greater opacity, and is consequently less prone to halation, and two parts of emulsion made by what is known as the ammonia method. These emulsions have the same composition as that of the undermost layer except that they contain only ·33 part iodide of silver, and have the greatet degree of sensitiveness which it is possible to obtain at the present time and by the present methods.

The undermost film or layer of a trebly-coated plate is composed preferably of an emulsion prepared by heat alone and brought to a sensitiveness represented by five on the Warnerke sensitometer. In composition it resembles the previously-described emulsions, except that iodide of silver is omitted from, and citric acid one part added to, the formula already given. The upper layer of a trebly-coated plate would be the same as described for the upper layer of a doubly-coated plate, and the intermediate layer of the trebly-coated plate would be the same as the undermost layer of the doubly-coated plate.

Having now particularly described and ascertained the nature of the said invention and in what manner the same is to be performed, I declare that what I claim is—1. The preparation of sensitive photographic plates having two or more superposed coatings or layers of gelatine emulsion which possess in regular gradation from the undermost to the uppermost coating or layer, progressively increased degrees of sensitiveness to light, substantially as and for the purposes described. 2. In the manufacture of sensitive photographic plates, the combination of two or more superposed coatings or layers of gelatine emulsion possessing in regular gradation from the undermost to the uppermost coating or layer progressively increased degrees of sensitiveness to light, so as thereby to lessen the liability to solarisation and halation, as specified.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

DECEMBER 13, the President (Captain W. de W. Abney) in the chair.

It was announced that the Hackney and Cheltenham Photographic Societies had been admitted to affiliation of the Society.

The following seventeen gentlemen were elected members of the Society:—Messrs. Wilson, C. P. Canstine, J. A. Sinclair, Wm. Taylor (Leicester), G. E. Franklin, W. Kerman, Lieutenant G. A. Beasley, Charles F. Treble, A. Pumphrey, Captain W. A. Gale, B. H. Thwaite, Birt Acres, E. C. Hertslet, H. A. Chapman, George Mason (Glasgow), A. F. Mowll, and H. A. Morrison.

PHOTOGRAPHIC LENS TESTING AT KEW.

MAJOR LEONARD DARWIN, R.E., M.P., read a paper on this subject. [This will appear in a future number.] He observed that he had already written one exhaustive paper for the Royal Society [see THE BRITISH JOURNAL OF PHOTOGRAPHY, *ante*], which left him little new to say, so that he was obliged to repeat in substance much that he had said before, dwelling, however, with more force on the practical side of the question. At the conclusion of the paper,

Mr. W. E. DEBENHAM said it was very desirable to have such an institution as that at Kew, and he hoped it would put an end to some wrong notions which photographers had cherished so long, particularly one as to certain lenses and their "depth of focus." He hoped that in future they would not see advertisements of lenses having greater depth of focus than others. As to the term "covering effectively employed" to distinguish narrow, medium, and wide-angle lenses, he thought, as "effectively" meant a certain amount of definition, the term should more properly be "defining effectively" with regard to a certain standard. Definition that was satisfactory for one subject was not so for another; it was considered prejudicial by some photographers. As to photographers not using a larger stop than that for which the lens was tested, many people preferred a picture which was darker towards the margin than at the centre; and he did not think that it was desirable to define any point beyond which a negative should be considered inferior as regards equality of illumination. For the sake of enlargements, it was desirable to ascertain the focal length accurately. Adverting to the battle of the standards, he said that lest it should be supposed that the Congress International standards had been universally accepted, he would point out that he considered the decision of the Photographic Convention as valuable as that of the Paris Congress on the subject.

Mr. T. R. DALLMEYER gathered that the Kew authorities had some little trouble about having lenses sent to them with a "supposed" covering power; but he thought that if they at Kew would simply take the lens sent as though they knew nothing about it, say what it would cover with various stops down to a low intensity and mention the circles of illuminations at those apertures, an ordinary photographer would be able to judge of the capabilities of the lens, and whether it would fulfil its purpose. With regard to the C.I. system, he was much in favour of it. Major Darwin would, no doubt, agree that it would be an advantage to have the circles of illumination with the full stop and a small stop, and if both were mentioned it might be useful. Flare spot was a point of great importance. With a large number of concave surfaces towards the plate, reflections were re-reflected. "Definition" might be settled in a more definite manner by referring to the question of separating power. Actinism might be put to a practical test with the focimeter. The practical test as to how a lens performs at the margins of the field was one that fell to opticians themselves, and he should like to see it acknowledged by the Kew authorities by a method of testing. It was not wanted with absolutely symmetrical lenses, but great skill was required with unsymmetrical lenses.

Mr. J. R. GOTZ suggested that tests should be applied to fixed diaphragms between lenses in order to ascertain whether the apertures they represented were correct.

Mr. HUGO (of Kew), who has the practical work of lens-testing in hand, found that in testing lenses two or three times the results were very accurate.

Mr. H. CHAPMAN JONES asked whether simple inspection was considered sufficient test for flare spot? He found that it showed more clearly with small apertures than with large ones. He had recently been using two lenses with smaller stops than hitherto, and they both gave flare spot. The stops were so small that he could hardly see the image.

In replying on the discussion, Major DARWIN said the Kew Committee would consider the suggestions made. With regard to Mr. Debenham's criticism on the term, "effectively defining," the case might be met by the omission of the word effectively. Respecting the same gentleman's remarks as to people who might prefer a picture which fell off in density at the edges, he (Major Darwin) thought most people would prefer an evenly-illuminated field. The test for flare spot ought to be done by means of photography, but it was impossible to introduce photographic tests at Kew. They did it as well as they could, and kept a sharp look out for flare spot with small stops. As to Mr. Dallmeyer's remarks with regard to the different sizes of plates a lens would cover, they would receive attention. They, however, could not get a good test object for a separating system. They must at Kew test on near and small objects on account of the atmosphere. In conclusion he said it would have been difficult to get the testing system to perfection without the assistance of Mr. Hugo.

Mr. FRANCIS GALTON, F.R.S., the Chairman of the Kew Committee, said that the instrument worked charmingly. They had enlisted the services of competent people.

The PRESIDENT, in moving a vote of thanks to Major Darwin, suggested that the Kew Committee should do what the Science and Art Department did with papers that did not obtain a certain percentage of marks. Bad lenses should be charged a double fee, and that might prevent a great deal of useless work. It was often not worth while to go into all the descriptions, for there were certain lenses on the market actually not worth the testing fee. As to the C. I. system, as a delegate of the Society, he was instructed to opposed it, and he did; but he hated the metrical system, and would not even think in it. He always spoke in feet, inches, and grains, and he hoped it would give people a great deal of trouble in reading his papers; so that he agreed with both Major Darwin and Mr. Debenham. He thought the Kew method of testing satisfactory for oblique pencils.

The meeting then terminated.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 8,—Mr. R. Beckett in the chair.

Messrs. H. E. Farmer, W. F. Slater, and C. H. Oakden were unanimously elected members.

FERROTYPE PHOTOGRAPHY BY FLASHLIGHT.

Mr. L. Nievsky gave a demonstration of ferrotype photography by flashlight, employing for the purpose plates and apparatus of his own preparation and invention. Forty ferrotype plates which are coated with a gelatine emulsion are contained in sheaths and held in a tin box, from which they are bodily transferred to a plate box placed on top of the camera proper. When the sitter has been focussed, by means of a lever movement a plate is placed in position, and the exposure given to a magnesium flashlight (the lamp being secured in juxtaposition to the camera). The exposed plate is then released and dropped into a small tank, and by the pressure of three rubber bulbs the developer, the fixing solution, and the wash water, are successively applied to it. The time of development is largely influenced by the temperature of the solution, thirty to forty seconds being sufficient in summer. Mr. Nievsky uses a hydroquinone developer which, on this occasion, contained a small proportion of hypo. Several successful pictures of members were taken.

ACTION OF SEA WATER ON PHOTOGRAPHIC APPARATUS.

Mr. P. Everitt showed a dark slide (of Messrs. Watson's manufacture) which, with a camera and other slides, had been several months under water. The particular slide shown seemed, on the whole, little the worse for the immersion. The shutters of the slide were considerably bulged with moisture

when Mr. Everitt obtained the apparatus, but they had since dried out quite flat.

Mr. A. Haddon would like to know the composition of the varnish with which the slide had been varnished. It had apparently resisted the action of sea water for several months, and might be useful to photographers.

QUESTIONS.

The following question from the box was read: "In what form is uranium deposited when used for toning bromide prints?" The answer given was, "Ferrocyanide of uranium."

Question No. 2: "In the preparation of stereograms for the stereoscope, should the distance of separation determined be the measure between two similar points in the foreground of the picture or between two similar points in the distance? In Chadwick's Manual it states that in all measurements it is the foreground only which must be taken into account, and the distance takes care of itself. The questioner finds it impossible to reconcile this with the theory set forth on p. 13 of the same work."

The member who had put the question said that it appeared to him that the separation of the distant points would have to be greater if two objects in the foreground were to be separated, say, two and a half inches. He had always found it more satisfactory to measure points in the distance.

Mr. W. E. DEBENHAM agreed, and also thought that stereoscopes should have a lateral movement of the lenses, so that slight differences in the mounting might be overcome.

Question No. 3: "Is a lantern slide a picture?"

Answer: "As much a picture as any other photograph."

North Middlesex Photographic Society.—December 2, the President (Mr. J. W. Marchant) in the chair.—The meeting was chiefly engaged in the nomination of officers for election at the annual general meeting, and other formal business. A discussion took place upon the Exhibition, and unanimous approval was expressed at the Judges' action in enhancing the value of the certificates by reducing the number of awards to five, as the exhibits to which they were awarded were remarkably in advance of the others. It was announced that the first of a series of class meetings for the instruction of beginners in technical matters would be held in the first week in the new year. The subject had been under consideration by the Council for some time, and it had been arranged that the lessons should be confined to simple technical matters, and that the work should be done by the pupils under the instruction of one of the other members. A limited number of non-members of the Society who are beginners in photography will be welcome at these classes. Application should be made to the Secretary.

Hackney Photographic Society.—December 5, Mr. R. Beckett in the chair.—The Hon. Sec. announced that the next meeting would be set apart for demonstration by Mr. Walter E. Woodbury, on lantern slides, &c., by printing out.

South London Photographic Society.—December 5, 1892, the President (Mr. F. W. Edwards) in the chair.—A demonstration of enlarging in creaco fylma was given by Messrs. Hill, the method of using which has already appeared in these columns. At the conclusion of the demonstration, in answer to questions, Messrs. Hill stated that the process could not be successfully worked with a negative which had been previously varnished. Pyro-developed negatives were not so suitable as those developed with hydroquinone, rodinal, or amidol, the clearing solutions containing alum, used with pyro, having a retarding action on their solution. They claimed that the process did not produce distortion, and in support of this contention an enlargement of the interior of a church was produced, in which the lines were absolutely straight. Enlargements revealed detail which was not visible in the original negative, and a suggestion was made that this property might be made use of in revealing the structure of objects photographed by the means of photo-micrography.

Bolton Photographic Society.—December 6.—Mr. C. K. Dalton (the Secretary) read the annual report of the Council. This set forth that the members numbered eighty-one, and they had had one of the most successful years in the history of the Society. The Council regretted that the proposed "survey" of the town had not been actively followed up, but the question would again be brought up in 1893. The report was unanimously adopted.

Liverpool Amateur Photographic Association.—December 8.—From the report of the retiring Hon. Secretary, Mr. F. B. Illingworth, it appeared that the Association had, during the past year, taken the handsome and commodious premises which were now occupied. The new rooms were opened in June last, and, although the subscription had been raised in order to provide improved accommodation, the membership had increased, and there were on the rolls at the end of the year 309 members. Mr. A. J. Cleaver was elected President in the room of Mr. Wm. Tomkinson. Mr. J. H. Welch was appointed Hon. Secretary, and Mr. P. H. Phillips re-elected Hon. Treasurer. The Council were also appointed. Subsequently the President announced the list of the Association awards in the Annual Competitive Exhibition of prints and Slides. They were as follows:—Prints (half-plate and under), silver medal, Mr. G. A. Carruthers; bronze medal, Mr. F. K. Glazebrook; commended, Mr. T. B. Sutton. Over half-plate, silver medal, Mr. T. F. Lloyd; bronze medal, Mr. C. A. Timmins; commended, Mr. H. Holt. Two enlargements, silver medal, Mr. T. B. Suttou; bronze medal, Mr. C. A. Timmins. Stereo slides, bronze medal, Mr. W. S. Ellsworth. Hand camera work, bronze medal, Mr. J. W. Swindon. Exhibits by those who had never won a Society's medal, bronze medal, Mr. G. A. Carruthers, commended, Mr. A. C. Batty. President's prize, lady members, three prints, Miss Rose Collier; commended, Mrs. Marriott. Lantern slides, silver medal, Mr. H. Holt; bronze medal, Mr. J. H. Welch.

Rochester Naturalists' Club (Photographic Section).—December 6, Annual General Meeting, Mr. C. Bird in the chair.—The following were elected officers for the season 1892-3:—*Chairman:* Mr. C. Bird, B.A., F.G.S.—*Vice Chairman:* Mr. J. Whitfield.—*Committee:* Messrs. J. C. Boon, J. Hepworth, J. S. Hewitt, P. J. Neate, T. F. Tannahill, M.B., C.M., D.P.H., and R. Watts.—*Hon. Secretary:* J. L. Allen, Clover House, Chatham. It was arranged to have the meetings during the winter fortnightly on Tuesday evenings at 8.15 p.m. The first meeting was fixed for December 20, when Mr. J. C. Boon promised to read a paper on *Wet-plate Process*, and to illustrate same.

Rotherham Photographic Society.—Dr. Baldwin (President) in the chair.—The results of the Society's annual (members') competition were announced as under:—Class A, six untouched negatives (President's prizes), 1; H. C. Hemmingway, 2; G. T. M. Rackstraw. Class B, three untouched negatives and three prints therefrom taken during the Society's excursion, 1, H. C. Hemmingway. Class C (for those who have not taken a Society's prize), four untouched negatives, 1, John Clarke. Four prints, 1, W. H. Shepherd. This class did not fill, but the Council decided that the awards should be given. Class D, six contact prints, 1, H. C. Hemmingway. Mr. W. Mason was not far behind. Class E, six lantern slides, 1, E. Isle Hubbard.—Mr. Richard Keene of Derby was the Judge, and he sent some useful and kindly words of criticism. A vote of thanks was passed to Mr. Keene for his services. The Annual Exhibition was fixed for February 7 and 8.

Edinburgh Photographic Society.—December 7. Mr. Alexander Ayton (V.P.) occupied the chair.—The first public business was the exposition by Dr. Drinkwater of samples of various methods of toning chloride and bromide of silver prints. The platino-toned prints showed full mastery of the system, and might compare favourably with platinum prints themselves. The bromides were toned to various tints more pleasing than the common blue, grey, cold colours or that style of printing. The Chairman, in summing up the remarks made on the Doctor's exposition, called upon the members to make and keep notes of their experimental work for the Society's use, and more especially so with the latest introduced gelatino-chloride papers, which he thought were rapidly taking the place of, if not superseding, albumenised papers for silver printing. Mr. Haddow then brought before the Society one of Dallmeyer's telephoto lenses, and in explaining its parts and uses said that the principle was applicable to any ordinary compound photo lens, the addition making it more nearly an example of the Galilean method of construction. He stated that for distant objects this form was decidedly preferable to the ordinary lens, as, although it reduced the angle of projected image, it at the same time enlarged it on the plate from five to ten times, roughly speaking; but the proportion being due to the added negative lens, which could be varied at will, keeping to the principle, the size of image for distant objects was, to a large extent, at the command of the operator, combined with his knowledge of the instrument and its powers of adaptability. Mr. Haddow handed round two views which he had taken about a week ago of a portion of the central tower of Fettes College, the distance as the crow flies being nearly a mile, the lines of the mason work and the divisions of the slating being quite distinct. Discussion on this paper was postponed till next monthly meeting.

Dundee and East of Scotland Photographic Association.—December 1, Lantern Evening.—Amongst the slides exhibited by members, one created a good deal of interest. The slide was from a landscape negative (a highland loch and fine clouds) by Mr. D. Ireland, and made on one of the new rapid lantern plates of the Paget Company developed with amidol. The slide had been under-exposed, and, coming up very slowly, was left for a long time in the developer. On the plate being fixed, it was found that the high lights—namely, the clouds—had developed a fine rosy-pink, and the water of the loch was slightly tinged, the whole giving a very fine sunset effect.

Correspondence.

THE SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the EDITOR.

SIR,—I notice a letter in your issue of December 9 referring to the late Exhibition in South London, and signed by one covering his identity under the pseudonym of "Young Member." At least one statement is made in this letter contrary to fact. The jurors did *not* "have in their hands catalogues which give the number and name of exhibitor clearly set forth," nor did we ever see any catalogue until the awards were all made on the merits of the pictures. In fact, this very circumstance caused us considerable trouble, because we found that awards had gone where the conditions did not allow them to go in several cases, and we had to rearrange our list of winners in order to meet the conditions laid down in the prospectus, awards in several cases going to those who had already got others.

I do not think the system of hanging the frames was the best, as, among other things, it caused much extra trouble to the jurors; but this is merely matter of opinion, and the system adopted had certainly some good points; but I do protest against statements made without proper inquiry into their truth, especially when they are insinuations against the good faith of executive and jurors, and I do further protest against such ungentlemanly allusions as appear in this letter of "Young Member" to the "stature and physique" of Judges at an exhibition. I can tell you and your readers that Judges have a sufficiently rough time during and after some exhibitions (I allude to mental, not bodily, hardship), without offensive and inconsequent gibes about their physique. It is about time that all anonymous criticism of Judges' awards should be suppressed; such criticisms are seldom unbiassed, and are often made scaffolds for purely personal abuse.—I am, yours, &c.,

ANDREW PRINGLE.

Cromwell House, Bexley Heath, S.E., December 10, 1892.

To the EDITOR.

SIR,—In your current issue you published a letter signed "Young Member," which contains an insinuation which I cannot let pass without a protest. The Judges never had the catalogue in their hands while judging, and, furthermore, the names of the successful exhibitors became known to them only after their awards had been communicated to the Hon. Secretary.

Although I never have felt anything but scorn for persons who, as in this case, make such insinuations under an anonymous signature, I must, nevertheless, express my gratification at "Young Member's" remarks concerning the Judges' "good stature and fine physique."

Our good stature and fine physique, however, did not prevent us from groping about on the floor and examining the exhibits he alludes to.—I am, yours, &c., F. P. CEMBRANO, JUN.

10, *Cambridge-gardens, Richmond Hill, Surrey, December* 9, 1892.

To the EDITOR.

SIR,—I only propose to refer to two points in the letter signed "Young Member" in your last issue, as it deals mainly with matters which are not of general public interest, but such as should be dealt with by the Committee of the Society.

When the Judges came to the Exhibition, I furnished them only with particulars of the various classes and the numbers of the pictures entered for competition in each of them, and with this information they proceeded with their work. It was not until after the judging had been completed and the awards signed that copies of the catalogue were handed to the Judges.

With reference to the showing of lantern slides, no distinction was made between any of the competitors, and if any of the pictures remained on the screen longer than others, the delay arose simply from the time occupied in finding and handing up to the operator the next reis, the adjustment of the lime, and matters of that kind.—I am, yours, &c.,

December 12, 1892. CHAS. H. OAKDEN, *Hon Secretary.*

[The writer of the letter signed "A Young Member" assured us that by publishing it a favour would be conferred upon a large number of members of the Society, and that the Society in general would benefit thereby. He also stated that he would be willing to give his name and address later if found advisable. Possibly, in view of the fact that two of the judges state clearly that his insinuation as to their having judged with the assistance of the catalogue is unfounded, he will, when acknowledging the correction next week, redeem his promise.—ED.]

PHOTOGRAPHY IN SOUTH AFRICA.

To the EDITOR.

SIR,—Some few weeks ago there was a paragraph in one of the papers stating that there were only "four good photographers" in South Africa.

At the present time there are *four good* ones in Cape Town, and several others of a lower grade. You will also find *good* photographers in Port Elizabeth, Kimberley, East London, Johannesburg, and all other towns of any size, and in some places the competition is as keen as in England.

Grahamstown, with a population of less than ten thousand, has about half a dozen, and you can scarcely find a village that has a population of over five hundred that has not got a photographer, or else is visited by the one from the nearest town or village at regular intervals.

There are also plenty of amateurs out here. There are five in this town, and yet this town (or village) has only a population of about a thousand whites.

Any one wishing to know the number of photographers out here can find out by referring to the *Argus Annual*, which can always be seen at the offices of the steamship companies.—I am, yours, &c.,

R. STEPHEN HILL.

Beaufort West, South Africa, November 20, 1892.

VOLUMETRIC TESTING OF ALKALINE HALOIDS.

To the EDITOR.

SIR,—In answer to F. C. Green I would say that Abney's statement (*Instruction in Photography*, p. 4) that the light affects only an "infinitely small proportion" of the sensitive compound gives one reason why, in the volumetric testing of bromide by means of silver, daylight need not be avoided. Another reason is the shortness of time required for the test. In gravimetric determinations of haloids by means of silver nitrate, or of silver by means of common salt, care should be taken not to perform the test in direct sunlight.—I am, yours, &c.,

December 9, 1892. J. H. PAYNE, F.I.C.

FUGITIVE IMAGES ON CELLULOID FILMS.

To the EDITOR.

SIR,—Under your "American Notes" in your issue of December 9, Dr. Charles L. Mitchell, speaking of celluloid films, refers to some of American manufacture being untrustworthy, and among other faults says, "They seemed to lose their image unless developed immediately after exposure." I have recently had a most striking example of this failure of films.

A gentleman recently returned from the West Coast of Africa asked me to develop a number of films he had exposed during some months of travel there. Before doing so I exposed a few (which he had brought home unused) in the studio for the purpose of testing the developer, &c., and they gave bold, vigorous negatives, clear and full of detail, while those exposed in Africa, although more carefully developed, gave only the most vague and ghost-like images, quite evidently the loss of power in the latent image. The pictures, thus practically lost were of great interest.

In view of the many advantages of films for work during travel, it would be well if the cause of this failure was made known, so that precautions might be made against it.—I am, yours, &c. P. HORSBURGH, Jun.

131, *Princes-street, Edinburgh, December* 9, 1892.

DIPPING-BATH DEVELOPMENT.

To the EDITOR.

SIR,—I am pleased to see in the last issue of THE BRITISH JOURNAL OF PHOTOGRAPHY some of the advantages of dipping-bath development mentioned. The dishes generally in use for the purpose bring such a large surface of the developer into contact with the air that its energy is wasted, and very many have to use sulphite as a preservative, a thing I strongly object to, preferring to use successions of fresh developers.

I have long been wishing that a dipping bath suitable for one, or for a few negatives at a time, were introduced, but, so far, have not succeeded in hearing of one. The obvious advantages are numerous, including (with a glass bath) the viewing of the negative by transmitted light without removing it from the dish, also that the negative can be left to itself to work up for a long period without rocking. Perhaps some provider of photographic materials would give the matter consideration.—I am, yours, &c., LOUIS MELDON.

Dublin, December 10, 1892.

WEST LONDON PHOTOGRAPHIC SOCIETY.—December 20, Technical Social Meeting.

PHOTOGRAPHIC CLUB.—December 21, *Amidol and Other New Developers.* 28, Monthly Lantern Meeting.

BRIXTON AND CLAPHAM CAMERA CLUB.—December 20, *In Spain with a Camera*, by Mr. F. P. Cembrano, jun. Public evening; invitation tickets from Hon. Sec.

WE are happy to hear of the engagement of Miss Catharine Weed Barnes, of New York, to Mr. H. Snowden Ward. Miss Barnes will still continue her editorship of the *American Amateur* and her other literary work.

THE next ordinary meeting of the Photographic Society will take place on January 10, 1893, when Mr. John Spiller will read a paper on two new developers, and Mr. H. Chapman Jones a paper on *A Chemical Study of Mercurial Intensification*. There will be no Technical Meeting this month.

THE Cleveland Camera Club will hold an exhibition and conversazione at the Co-operative Hall, Corporation-road, Middlesbrough, on Wednesday, February 1, 1893, when six medals, three silver, and three bronze, will be offered for competition in the following classes. Members only: 1. Set of six photographs (mounted on one mount). Open to all: 2. Single photographs (any subject). 3. Lantern slides, sets of six. Application for entry forms should be made to the Hon. Sec., Mr. J. J. Hallam, 11 Amber-street, Saltburn-by-the Sea.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

J. P. (Wimborne).—Mr. H. N. King's offer was undoubtedly a genuine one.

ERNEST BASSETT.—Put the case in the hands of the Superintendent of Police in the town where the man lived.

F. PETERSON (Nottingham).—Fluoride of silver is not employed in photography, although its properties are known.

XYLOGRAPH (Surbiton).—The specification may be obtained at the Patent Office for eightpence when published.

C. W. FENTON.—If you continue to apply the ammonia solution to the precipitate (which is silver oxide), it will dissolve.

H. HEWSON AND OTHERS.—Thanks for the Imperial Portrait Association circular. We are tired of denouncing the scheme.

S. YEMENS.—Several formulæ for varnishes that are suitable for gelatine negatives are given in the ALMANAC, to which please refer.

B. R. T.—To prevent the glass stopper from again sticking in the bottle, clean it thoroughly and apply a little vaseline. Very little will suffice.

L. GILSON.—You will see that we have some remarks on brush development in a leading article this week. Thanks for the information on the other subject.

"An Old Hand," who writes us a letter *dpropos* our article of last week on "Recent Exhibitions," has, with the characteristic carelessness of "old hands," omitted both his name and address.

Several correspondents have sent us spotty prints, for the causes of which we must refer them to previous answers given in this column. Spots in prints have apparently once more assumed the dimensions of an epidemic.

J. Brier.—The thinner sample of tinfoil sent is too thin and very full of holes. The kind usually employed is of an intermediate thickness between the two samples. Any operative chemist will be able to supply what you require.

C. Rains.—As carbon tissue is now supplied in small quantities, sensitised and in the proper condition for use, you will do better, as a beginner, to purchase it in that state than to sensitise it yourself. Where a certain degree of proficiency has been acquired, then by all means sensitise it for yourself.

Nixon.—If the previous picture has stained the opal glass so that it cannot be cleaned, even with cyanide of potassium, the only way to remove the stain is to grind it out with emery powder or fine graining sand. Whether the value of the glass, now that it is so cheap, will repay for this trouble depends upon the value put upon time.

B. Symington.—If the photogravure is copyright, it would be legal piracy to copy any portion of it as a lantern slide, even were it only to illustrate a lecture on art. It is just possible, if you fully explain to the holders of the copyright the purpose for which the copy is wanted, they may accord you permission. Better write to the publishers.

S. W. says: "I have a pair of old stereoscopic portrait lenses and they both give equally as sharp images on the focussing screen, but in the negative one image, the left, is always much sharper than the other. Can you account for this?"—Yes. The reason probably is that in one lens the chemical and visual foci are coincident and in the other they are not.

West.—The arrangement shown in the sketch will answer very well for enlarging, but there will be a great loss of light, that is, an unnecessary quantity of magnesium will be required, owing to the length of focus of the condensing lenses. If they were half the focal length or a little less, they would answer the same end and economise magnesium.

T. Brain.—The precise position of the stop is not of vital consequence in your lens. The nearer it is to the lens, the greater will be the area of illumination, accompanied, probably, by a falling off in the definition at the margin. If this be so to any considerable extent, you can easily remove the stop to the position it occupied previous to its being sent for repairs.

D. McPherson.—It would certainly be bad policy, if nothing else, to exhibit a collection of portraits that have been rejected by sitters, however good the photographs may be, in a window or show-case. We can quite sympathise with photographers in the matter of the fastidiousness of sitters, but the step suggested would be very unwise from, at least, a business point of view.

Geo. S. Chase.—A method of making nitrate of ammonia which is much recommended consists in mixing a saturated solution of sulphate of ammonia with a saturated solution of nitrate of strontia. Sulphate of strontia falls as a precipitate, the nitrate of ammonia remaining in solution. The precipitated sulphate of strontia is reconvertible into the nitrate by means of dilute nitric acid.

H. B. says: "Your correspondent, 'Devonshire,' will find what he wants in the Almanac for 1892, page 572: 'An Imperishable Mountant,' by the Rev. J. Carter Browne, D.D. I send you a photograph I have just printed, with particulars at the back of lens, formula, &c. How do you think amidol has answered as developer?"—The print sent by our correspondent is a truly excellent one, definition, exposure, printing, &c., being faultless.

Amateur (Warwick) writes:—"In formulæ, water, sixteen ounces, and water, one pint, are often written; are not the two synonymous? Is not a pound of water and a pint of water the same quantity? That being the case, why this confusion in writing quantities?"—Our correspondent is under a misconception, a pound of water and a pint of water are not the same; the former is sixteen ounces and the latter twenty, or a pound and a quarter.

W. S. B.—If the premises were taken on a repairing lease, the landlord cannot be expected to do any repairs to the studio, any more than he is to any other part of the building. The fact that the studio was "slop-built" does not matter. The tenant ought to have satisfied himself as to the condition of the premises at the time he agreed to take them. Having signed the lease, we expect he will have to abide by its conditions, whatever they may be.

J. A. Biggs.—Place the two large lenses *much* closer together than shown in the drawing, and both with their flat sides next the light. Let the carrier for the negative be nearer the condenser, and use a ground glass or opal only if the illumination of the negative is unequal. The lamp will have to be placed a considerable distance from the condenser, this distance being ascertained by seeing that the cone of light passes through the enlarging lens in front.

B. Morris writes: "I find a difficulty in keeping bromide paper flat and even while enlarging, particularly when it has been kept in a warm room. Would there be any injury to the resulting picture in the matter of sharpness or in other ways if the paper were pressed in contact with the board with a sheet of glass?"—Practically, there would be no loss of sharpness or other deterioration by adopting the method suggested. The glass must be perfectly clean, free from scratches, air-bells, and other defects; otherwise they would be rendered in the picture.

A. J. says: "I am much troubled by a difficulty in mounting. I have tried starch and dextrine, and find that, whilst most of the pictures adhere well, some of them will always leave the mounts a little at the edges, and will come off more still when burnished. Could you suggest what is likely to be the cause?"—It is pretty obvious that the mountant is not evenly applied. The edges are not sufficiently coated with the cement. It is necessary that a good coating of the cement, whatever it may be, is applied to the extreme edge of the print, or the trouble complained of is sure to be experienced.

Noel B. Kenealy says: "May I venture to ask if any of your readers can help me out of a difficulty? I have been trying for months to make some collodion dry plates (not emulsion), but have hitherto failed. I shall be glad to hear from any one who has practically worked the process, and, as a successful result will mean a good deal to me, I shall not be ungrateful. My plates have always lacked evenness and density, and I must have a very black and white result."—Our correspondent evidently refers to collodion preservative processes, of which he will find every particular in former volumes of this Journal and its Almanacs.

B. J. Burridge.—A four-and-a-quarter-inch condenser is not large enough to illuminate a quarter-plate negative, hence the cause of the dark corners in the picture. The defect is not due to the lens or to the light as surmised, but simply because the condenser is not large enough for the work. For enlarging, to secure even illumination, the condenser must not be less in diameter than the diagonal of the negative to be enlarged. That, in the case of the quarter-plate size, is nearly five and a half inches. For perfect illumination, taking marginal imperfections and the mounting into consideration, a six-inch condenser is preferable to the size mentioned.

F. E. G. writes: "Herewith I beg to enclose cabinet photograph on P. O. P., on which you will observe a number of faint dark spots which appear when put through the hot burnisher. It is not impossible that these marks are on before burnishing, but the heat probably makes them more visible. I have had quite a dozen this last fortnight, and would be glad to find the cause of them. It does not come from the negative, as good prints are got from same negative. The prints are never allowed to rest in fixing bath."—The spots appear to be due to imperfect fixation. Probably air-bells attach themselves to the surface of the paper, and thus prevent the free action of the "hypo" at those parts. There is little question that the spots are present before the burnishing, but they are rendered more manifest by the operation. The burnishing is certainly not the cause of the defects.

Mr. Jonathan Fallowfield has been appointed London wholesale agent for Wood's Washer Company.

We have received the new catalogue of the Thornton Pickard Manufacturing Company, which contains particulars of several new items, including the snap-shot shutter, a new safety blind, a new dark-slide recorder, the improved focal plane shutter, &c. The illustrations of pictures taken with this and the "Instantaneous and Time" shutter are capital testimonials of the efficiency of those instruments. This little catalogue contains many hints of use to shutter-users.

The Woolwich Polytechnic Photographic Society will hold an exhibition of photographs and apparatus in the Large Hall, Woolwich Polytechnic, on Thursday, Friday, and Saturday, February 16, 17, and 18, 1893. The Judges are Messrs. F. P. Cembrano, A. R. Dresser, and A. Pringle; and the following are the sections:—1. (For members only), Prints, any subject by any process. 2. (For members only), Lantern slides, best set of six, any subject. 3. Open to all amateurs, any subject by any process. 4. Open to amateurs who have never received an award in open exhibition. 5. Lantern slides, open to all amateurs, best set of six. 6. Hand camera work, set of four prints taken with camera held in the hand, not on a tripod (enlargements debarred). A gold medal, presented by the Right Hon. the Earl of Carrick will be presented for the best picture in the Exhibition, and silver and bronze medals and certificates in all classes, will be placed at the discretion of the Judges.

FORTHCOMING EXHIBITIONS.

JOURNAL OF PHOTOGRAPHY.

No. 1703. Vol. XXXIX.—DECEMBER 23, 1892.

A TELESCOPIC FOCUSSING FINDER.—II.*

The problem now to be solved—and it is happily one of extreme simplicity—is the application of the telescopic focusser to a camera in which more than one lens is to be used.

We have said that the object-glass of the telescope should be identical in focus with that of the photographic lens employed. Seeing this is to be the case, it follows that the object-glass in question must have a variable focus. This was foreseen at the time the appliance was first made and publicly shown. To the original one we had independent object-glasses adapted, these being respectively of eighteen, fifteen, and twelve inches focus, to suit the photographic lenses attached to a particular camera; but a much less costly alternative presented itself. This was to have only two object-glasses for the telescope, these being worked in conjunction.

One was fixed at the end of the body in the usual manner in a screwed cell. The other was similarly attached to a short bit of tube, which was made to travel easily from end to end of the main tube. By means of a longitudinal slot in the body and a projecting button, this inner lens was capable of being run from one end to the other, either close up against the primary or fixed object-glass, or comparatively near to the eyepiece end.

Now, according to the distance that one of these object-glasses is from the other, so does the focus vary. If each of them were of twenty-four inches focus, then, when placed close together, the combined focus would be twelve inches—that is, if we could suppose them to be infinitesimally thin. What we have to note in this instance is, that the farther they are separated from each other the longer becomes the focus.

The determination of this is effected by a rule which we quote from what we have elsewhere written. It is: "Having ascertained the focus of each of the object-glasses, multiply the focus of one lens by the other, and divide this product by the focus of both added together, less the distance of separation. The quotient is the focus sought for."

From this it will be seen how easy it is, having a combination objective in the telescope, to alter its effective focus to anything within reasonable limits that may be desired. Suppose that the primary focus of the telescopic objective is twenty inches, and that a supplementary lens set in the running or adjustable short tube is twelve inches, and it was desired that the combined focus should be eight inches, so as to suit a camera lens of that focus, then by the foregoing rule it would merely suffice that they be separated two inches, for—

$$20 \times 12 = \frac{240}{32 - 2} = 8 \text{ inches.}$$

in which the foci, when added together, give, minus two inches (those of separation), 30, the divisor for 240 (the product of multiplication of the foci), giving eight inches as the equivalent focus desired.

The same result may be arrived at by "trial and error," a system which some photographers may prefer to adopt. In any case, when the focus of the telescope is, by moving the running piece of tube round, to assimilate to that of any of the variety of lenses that it is intended to use with a particular camera, let an index mark be made on the outer tube to correspond with a like mark on the button, and by this means one will be able to play with the original telescopic focus to any extent.

We would not for a moment recommend this system for adoption, when a telescope is to be employed as such, for giving the acme of definition; for in such a case, and for such a purpose, it should be left in its native entirety; but, for the purpose now being advocated, it will answer exceedingly well. Nay, we find that, at a pinch, an uncorrected or single-glass lens, if edged down, may be made to subserve the purpose of the necessarily more expensive achromatic lens in the running or adjusting tube.

In conclusion, note that the shortest focus is obtained by placing the objectives close together; by separating them, the focus is lengthened.

* Concluded from page 802.

FIXING AND FIXING AGENTS.

The operation of "fixing" negatives or prints is too often regarded as one that requires little or no care beyond that involved in ensuring the complete removal of the unaltered silver salts—in other words, the sensitive material that has not been reduced either by the direct action of light or by the developer. Beyond this, which in itself is not a difficult matter, there are certain precautions to be observed in regard to the removal of the fixing salt itself, as well as of the products formed in the process; but these are well understood, and there, so far as the majority of workers are concerned, the matter ends. But there are other points to which it may be well to call attention.

The term itself has been objected to as a misnomer, since the removal of the unreduced haloids in no way affects the image already formed, or should not do if proper treatment is adopted; but, since age has sanctified it, we may still continue to employ it, and to consider as fixing agents any salts that are capable of dissolving iodide, bromide, or chloride of silver without materially acting upon the reduced metal forming the image.

At the present day sodium hyposulphite or thiosulphate reigns almost supreme as the fixing agent both for negatives and prints, but many other substances have been employed at various periods. In very early times iodide of potassium, chloride of sodium, and ammonia were used, according as the

sensitive material was iodido or chloride of silver, until "hypo" was found to be a better and more energetic solvent. Then cyanide of potassium came into use with collodion, and became the almost universal fixing agent for both negatives and positives. Later on, the alkaline sulphocyanides were proposed in place of hypo for fixing albumen prints, and in comparatively recent years chloride and sulphite of sodium have been put forward for the same purpose.

The merits and demerits of these various agents will be better understood if we consider for a moment what takes place in the process of fixing, or at least a portion of what occurs. The silver haloid in the course of removal is converted into a soluble double salt, in which condition it is particularly liable to act upon any organic matter with which it may be in contact, as, for instance, collodion, gelatine, albumen, or paper, one or other of which must necessarily be present in negatives or prints. The longer the fixing process lasts, the greater is the danger arising from this cause, hence the desirability of using a solvent that will remove the unaltered haloids as quickly as possible.

Few of our readers, we imagine, are unaware that, though paper or linen moistened with a solution of nitrate of silver may remain colourless for a time, it will eventually blacken without exposure to light; but perhaps it is not so well known that chloride or bromide of silver, dissolved in any of the fixing solutions mentioned above, will produce a similar, if not identical, result. Allow, for instance, a few drops of fixing solution from a print or negative to fall upon a sheet of white blotting-paper or linen, and in a few days or weeks an indelible stain will be the result, varying in intensity with the state of concentration of the solution, so far as concerns the quantity of silver it contains. If the paper or linen be at once washed in plenty of water, or before discolouration occurs be treated with a fresh solution of hypo, the stain will not appear, or, if it should, will be far less apparent, its intensity depending upon the thoroughness of the washing or the length of time the fixing solution is allowed to act.

In the case of a solution possessing comparatively little solvent action upon the haloid, it is clear that the negative or print will be subjected to the action of the soluble silver salt for a considerable time, and, what is worse, in the case of such salts as iodide of potassium or chloride of sodium, the dilution caused by washing is liable to throw down some of the silver in a more or less insoluble form. To avoid eventual discolouration with such fixing agents, it becomes, therefore necessary to employ a considerable volume of concentrated solution, which, added to the inconveniences of their tardy action, places them practically out of competition with hypo. The same fact prevails, as is well known, even with hypo, though, owing to the much greater solvent action of the latter, it is not so much felt; for if from using too weak a solution, not allowing it to act long enough, or attempting to fix too many prints or negatives in a given quantity, its strength be over-taxed, the inevitable result will be ultimate discolouration from formation of the unstable double salt.

The introduction of the sulphocyanides some quarter of a century back as fixing agents for silver prints was expected to do away with the trouble arising from fading and sulphuration of hypo fixing; but, unfortunately, the innovation did not prove a success, for the reason, as alleged at the time, that, though the unaltered chloride of silver might be removed, the albumenate was not. At any rate, the sulphocyanides have never been generally adopted. Similar objections were made to the use of chloride of sodium and sulphite of sodium when, a few years ago, it was proposed to substitute those salts for the hyposulphite, and, though we have in our possession some gelatino-chloride prints fixed with chloride of sodium several years ago which still retain their pristine brightness, there can be little doubt as to the immeasurable superiority of hypo, either for albumen or gelatine prints or films.

Cyanide of potassium, the once all but universal fixing agent for negatives, owes its replacement by hypo to other causes. In the first place, it is a powerful solvent of metallic silver, and therefore exercises an injurious action upon the developed image. In the days of wet collodion, when the sensitive film consisted mainly of iodide of silver, the ready solubility of the latter rendered it possible to use a solution of so low a strength as to have practically no injurious effect upon the image; while, for glass positives or ferrotypes, a slight action upon the metallic deposit had a distinct advantage in clearing the shadows. But, upon the introduction of simply bromised collodion, and subsequently of gelatino-bromide films, the superior solvent power of hypo for silver bromide, and the absence of any injurious action upon the image, threw cyanide of potassium altogether out of use.

There cannot be the shadow of a doubt that at the present day hypo is not only the best, but the only practical, fixing agent we have either for negatives or prints, however much it may be objected to on the score of some of its properties. It has been pointed out over and over again in these and other columns that much of the blame supposed to attach to hypo is really due to its misuse, and that, though the want of want of permanence alleged against silver prints generally has been laid to its charge, the fact still remains that many prints are still in existence without any symptoms of fading that were fixed with hypo thirty or forty years ago. Albumen, it is true has had a share of the blame cast upon it as helping towards, the want of permanence, but it is questionable whether the greater danger does not exist at the present day in connexion with gelatine.

The rapid discolouration or yellowing of so many gelatine prints both developed and direct is, no doubt, much of it due to imperfect fixation or insufficient washing; but at least some of it may, we think, be charged to over-fixing, or allowing the prints to remain too long in the hypo solution, especially when a considerable number are treated in the same quantity of solution. In such cases the fixing bath becomes converted into, practically, a solution of silver capable of forming an organic compound with the gelatine, and this, in the absence of a sufficiency of hyposulphite to retain it in the soluble condition, remains to cause the gradual discolouration of the print, although it may not be immediately apparent.

We know that, if a sheet of clear gelatine be soaked for a short time in a solution of silver nitrate, no amount of simple washing will suffice to prevent the subsequent discolouration of the gelatine, even if kept in the dark, while exposure to light will bring about the rapid reduction of the organic compound. If such be the case with a perfectly soluble salt like the nitrate, how much more likely is it to happen with the double hyposulphite formed in the fixing bath under the circumstances mentioned, prone as it is to decomposition into insoluble compounds.

The matter is easily tested by immersing a gelatine print, or, better still, a leaf of plain gelatine, in a perfectly colourless fixing bath well charged with silver, and, after a very thorough washing, allowing it to dry. In the course of a short time the

gelatine will be found to have acquired a decided tint, readily apparent when compared with a similar leaf untreated. If a portion of the gelatine be immersed in fresh hypo before the final washing, the part so dipped will remain unchanged, or show a much slighter colouration, on keeping. A print or negative left for a few hours in the fixing bath will acquire a distinctly, and sometimes a very marked, yellow colour, although the bath itself may be quite colourless, especially if several prints have been already passed through it.

The importance of using a fresh bath and plenty of it cannot be too strongly urged upon all producers of gelatine prints, and also of not allowing them to remain too long a time in the solution. As an additional safeguard, the practice of finishing off in a second and clean solution is one that can be recommended.

DIFFUSED LIGHT.

This subject, which embraces issues of the highest importance in photographic technics, has recently been treated very definitely, and from an exact standpoint, in a paper by Dr. W. E. Sumpner, read before the Physical Society. We purpose drawing upon the facts and data he then brought forward, but will first briefly survey the field covered by the subject. The paper has a more particular reference to indoor or otherwise restricted illuminations, hence a mere reference will suffice for that diffusion of light which plays so important a part in the various effects seen in nature, according to the extent and the direction of those media—clouds, atmosphere, and spacious reflecting areas generally—whose action makes or mars the possibility of pictorial treatment.

The first effects that would naturally present themselves to the investigator would be those met with in studio work. And very largely will they be seen to act. The light enters the studio through a given area of glass, but a little consideration will show that of the light entering such area a very small fraction only falls direct upon the sitter and the portion of his surroundings that ultimately appear in the picture. What, then, becomes of the rest? It is partly absorbed, partly reflected and diffused, a portion of the latter amount being again received by the sitter. Here, *en passant*, it may be remarked, is seen the advantage of electric lighting for portrait studies. When suitably used, almost the whole of the acting light is directed upon the sitter. The rest of the studio is in darkness, and so small a portion of the air has rays of light passing through it, that even on a foggy day, with fog in the studio, presentable portraits may be taken, when all-round daylight illumination would give worthless results.

Returning now to what may be termed the secondary light—the portion not radiating directly upon the sitter—we find a portion utilised and a portion wasted. It is almost a truism to say that, for the sitters' comfort and the quality of the negatives taken, all light not thrown upon the subject is worse than useless. Then we have to consider surfaces specially contrived—screens erected for the purpose of diffusing light. The light from a particular direction is considered too strong; it can be diffused by interposing a temporary screen of some translucent woven material, of tracing paper or cloth, by coating the glass with a diffusant, or, finally, by glazing with "ground glass." The respective values of these substances have never been given to the world, but Dr. Sumpner's paper gives many such data. We have to consider non-utilised light—light that enters the windows of a studio, but is of little or no value for the sitter's requirements. If the value of a diffuser is known, a suitably selected one may be placed in the path of the useless rays, and cause them to be diffused, a portion of them being thrown upon the sitter.

White or pale-coloured screens are employed as subsidiary illuminants, by reason of their diffusing properties, and, if the actual value of the various possible surfaces were known, it would not be difficult so to devise a screen that the maximum diffusion with the minimum incident illumination could be obtained.

Turning next to the dark room, it is quite evident that, when the popular coloured papers or cloths are made use of to give the proper colour to the light, there is not five per cent. of it used for lighting up the plate; by far the major portion is diffused, and lightens up the room itself; but, as far as regards the plate, one-fifth or one-tenth of the light (and concomitant heat) would illuminate the developing dish equally well, if the laws governing the diffusion of light were understood and their teachings utilised. The effects of diffusion, again, may be noticed from the walls of the room. Thus, of the light from the lamp or gas, there will be plenty of diffused illumination from the walls of the room. The particular illumination of a negative, for example, will depend upon its distance from the source of light, and whether or no a light-diffuser intervenes. If a pigment which only reflected red light could be found, and the walls and ceiling of a dark room were painted with it, there would be monochromatic diffusion, and a naked gas flame might be safely employed if an opaque object were interposed in the path of the rays from it to any uncovered sensitive plates.

If we next take into consideration the printing-room and its accessory aids, we shall find diffusion playing an all-important, but completely ignored, part, leaving out of question diffused skylight, for few printers use direct sunlight. There will be seen tissue paper to diffuse, cotton-wool to diffuse, vignetting glasses, cardboard, or other perforated screens, and many similar contrivances, all to take advantage of light so treated. But in all cases the treatment is empirical. It must often be so; but occasionally exactness would be a boon. The direction in which to look for this is indicated in Dr. Sumpner's paper, fuller details of which will be abstracted for a succeeding article.

A New Style of Portrait Wanted.—A correspondent, writing anent the depression of trade amongst professional portraitists, suggests that a new style of portrait should be introduced which amateurs could not produce. He says that "if such a thing were done, and it took, the trade would revive, and would then be entirely in the hands of the profession." The idea of a new style in portraiture is excellent, but the writer omits to say, or even to hint at, what kind of picture there is, or ever will be, that is beyond the scope of an amateur to produce. We await information on the point.

The Magnesium Light.—The application of powdered magnesium as a source of light for photographic purposes is by no means such a modern invention as some seem to suppose. So far back as 1865 it was used; and in that year Mr. H. Larkin obtained a patent for a lamp for its combustion. The lamp answered well, and we were present when some very good portraits were taken by its aid. In this lamp the powder, mixed with a certain proportion of fine sand, was made to pass through the flame of a spirit lamp, or one of gas, which ensured its combustion. The chief reason why the lamp was not much used was the then prohibitive price of magnesium.

A New Application of Photography.—According to one of our contemporaries, whose special sphere is dress and fashion, some West-end milliners are sending out to their customers photo-

graphs of bonnets and hats of the latest design, from which they can select. The suggestion is made that, in preference to this system, the ladies should send their portraits to the milliners, and allow them to use their judgment as to the *chapeau* and trimmings that would best suit the face. The idea certainly bears the stamp of novelty. We should certainly advise the milliners, in using their judgment, to err on the side of supplying the article quite in unison with the youthfulness of the "highly" retouched photographs of some middle-aged ladies, than otherwise, or it may not give satisfaction. But there, the fashionable *modiste* requires no "tips" from photographers on this subject.

Stained Prints.—*Apropos* of the subject of spots of a mysterious nature that seem to make their appearance periodically, there are certain stains that may be said to do the same. These, too, may be attributed to the season, and they are not confined alone to albumen prints, but extend also to gelatino-chloride printing-out paper. In a sense they may be classed as "spots," though stains would be a more appropriate term. When an albumen print is transferred from a solution of one temperature to that of another, it is often noticed that air bells will adhere very tenaciously to it; consequently the surface is for a time protected. If this occurs in the toning bath, stains or unequal toning will occur; if in the fixing bath, uneven action of the hypo, resulting in yellow spots. To some kinds of gelatino-chloride paper air bells seem to adhere more tenaciously than to albumen paper; hence they must be guarded against. There is another cause of stains which has often been pointed out, and is well known to experienced workers, namely, the slow action of the fixing agent at a reduced temperature, and that a longer time for fixation is necessary. But this has been so frequently dwelt upon that it need not be further alluded to.

Spots.—The spot epidemic appears to have set in with unusual severity this winter, if we may form an opinion from the number of letters received on the subject during the last two months or so. It has been noticed for many years past that "mysterious spots" on silver prints are more prolific during cold weather than at other times. On previous occasions we have directed attention to the fact that an often unsuspected cause of spots is floating particles of pernicious matter in the atmosphere in the form of dust. In winter, when the work-rooms are artificially heated, the atmosphere becomes very dry; consequently, when the floors are swept, considerable dust—which is generally composed in great measure of the chemicals in daily use—is raised, the finer particles of which take a long time to settle, and, if they alight on wet or damp prints, which are usually in course of drying or mounting in the ear part of the day, when the cleaning is done, they will have their effect. A particle of hypo, bichloride of mercury, &c., settling on a moist print, would eventually cause a spot. The sulphurous dust, too, from a coke stove also has a very pernicious effect, and is sometimes a prolific source of spots. By way of experiment, we have allowed some to settle on a moist print, with the result that in a few days it was covered with spots very similar in appearance to some of those on prints that have recently been sent us.

Sale of Poisons.—Dealers in photographic materials need be cautious just now as to the selling of some of the chemicals used in the art. According to the Pharmacy Act, some of them can only be vended by duly certified pharmaceutical chemists. The Pharmaceutical Society is very jealous of any one trespassing on its domains—the chemist's and druggist's business—and at present, as it is occasionally, it is active in prosecutions. Last week it proceeded against some grocers for penalties for selling a bottle of proprietary medicine—Dr. Collis Browne's chlorodyne—because it was said to contain opium, one of the poisons scheduled in the Act. The decision was in favour of the Society, but it is to be appealed against on technical grounds. The Judge, in his summing up, is reported to have said: "It seemed to him almost too clear for argument that a poison, however mixed up with other things, did not cease to be a poison." No one who has the slightest acquaintance with it will fail to be amused at Judge Bateman's idea of chemistry. Fortunately, there are only a few of the chemicals used in photography that are named in the schedule, amongst which may be mentioned bichloride of mercury and cyanide of potassium. These it is illegal for any one but a fully qualified pharmaceutical chemist to sell, and then only when certain formalities are gone through both by purchaser and seller. Of this there is no question. Wholesale dealers may, however, sell these, and other materials, in wholesale quantities without hindrance. Hence there is less difficulty in obtaining a few pounds than an ounce or two of some things.

ELECTRICAL ACTION IN DEVELOPMENT.

In a recently published number of *L'Amateur Photographe*, Mons. L. Mathet describes some experiences of electrical action in the development of celluloid films. He noticed in developing some films of his own preparation a phosphorescence-like appearance on the surface of the negative; a phenomenon which also appeared when he repeated the experiment with rollable films of commercial manufacture. The circumstances under which the phenomenon appeared in the latter case were as follows:—The films were developed in an ordinary vulcanite dish, with pyro-soda. While flowing the developer to and fro over the film he clearly noticed, he says, a phosphorescent gleam upon its surface. When development was complete the developer was removed, the film allowed to adhere to the bottom of the tray, and flooded with the wash water, when the mysterious light became even more apparent. The negative, when fixed, was slightly veiled. Substituting a hydroquinone developer for the pyro-soda with other exposed films, the same "phosphorescence" appeared, and subsequent slight fogging also supervened.

M. Mathet regards these experiences as confirming the conclusions of Colonel Waterhouse (see the last volume of this JOURNAL) that an electro-chemical action is producible during development; but in M. Mathet's case this action is made apparent by the nature of the support. That gentleman, however, points out, what, of course, is tolerably well known, that celluloid is a bad conductor of electricity. When talced glass is coated with a solution of celluloid in amyl acetate and the dried film is stripped, a shower of small electric sparks is evolved between the detached film and the glass at the moment of separation. The pellicle, however, retains its electrical properties.

In coating large surfaces of rollable celluloid films M. Mathet points out a fact which we remarked upon some years ago, although the statement encountered the dubiety of an experienced dry-plate maker, that this non-conducting property of the celluloid may lead to the fogging of the superposed emulsion, the entire surface being fogged, and the discharge becoming visible on development. M. Mathet is inclined to think that the same phenomenon is the cause of the several small stars with which some of his film negatives were disfigured. He quotes the case of a commercial film which, upon development, showed a dark spot around which were formed certain regularly defined luminous radiations that he also sets down to the same cause.

M. Mathet states that if the celluloid film be coated while on a metallic surface, instead of a glass plate, as is generally used, sparks are produced if the film is forcibly moved in contact with the metal, and especially if the air be dry, while they may be avoided if the atmosphere be humid and care be taken to remove the pellicle carefully, and placed in contact with some inert material. Such facts are no doubt thoroughly known and understood by commercial manufacturers of celluloid films. The interesting point in M. Mathet's communication lies in what he regards as a confirmation from his own experiences, that, as Colonel Waterhouse and others have already discovered, an electrical action is produced in development. It should, however, be pointed out that in Colonel Waterhouse's experiments, if we remember aright, no sparks of electricity were visible.

JOTTINGS.

I AM glad to observe, from the reports lately published in your columns, that the Photographers' Benevolent Association, under its new Hon. Secretary, Mr. Snowden Ward, gives promise of entering upon a career of greater usefulness than it has hitherto enjoyed. The times are hard, and so soon as it becomes known amongst indigent

photographers and assistants that the Benevolent is anxious to extend a helping hand to those in need of it, I have no doubt that it will receive numerous applications for aid. But, alas! how many of those who seek its assistance in the hour of trouble can allege the inexpensive qualification of membership as a claim upon its consideration? Very few, I fear. The improvidence of actors is notorious, but, to judge by the paltry manner in which the Benevolent Association is supported by photographers, the latter are formidable rivals of the histrions. Surely it is time that each individual photographer in the country made an effort to remove this stigma from his profession. Come, gentlemen! A modest half-crown is sufficient to make you members of an Association to which one day you may be glad to turn for a "lift," and the name and address of the Hon. Secretary is, Mr. H. Snowden Ward, Memorial Buildings, E.C.

Having started these Jottings in a benevolent mood, and recognising that we have arrived at the so-called festive season of the year, I suppose I must bottle up for future use several choice growls which I had intended venting in this column just now. Never mind; I will keep them for next month—the Month of Growls, when the rent and the rates and the taxes and other impositions to which the inoffensive citizen is liable fall due. Still, I can't resist the temptation of mildly remonstrating with all concerned in the production of the new volume of The British Journal Photographic Almanac, for having made the book so big. If it were not that the pictures were so nice, the articles so practical, and the advertisements so interesting, I don't think I could forgive Messrs. Greenwood the piece of inexplicable philanthropy of selling for a shilling what is honestly worth five. When Macaulay's New Zealander comes over to sketch the ruins of St. Paul's from London Bridge, he will not improbably find a huge object in his line of sight which will prevent him seeing the dome. That object will, at its present rate of progression, be The British Journal Photographic Almanac of, say, A.D. 2000.

Nay, good "Immature," I am neither the champion of "scientific experts" as Judges of photographic exhibitions, nor of the other variety which seeks to ape in the camera the wildest eccentricities of Jemmy Whistler. I simply wanted to know why it is that "scientific experts" are now so vehemently objected to by certain persons as Judges, while for more years than you or I may care to count, their awards were cheerfully accepted, and (mark this!) intrigued and begged for. As you cannot, I will answer my own question. It is all on account of —not Eliza—but of the revolt of a reputable Society against privilege, impertinence, and favouritism (*vide* this Journal of December 11, 1891, pp. 798, 9). In those two pages you may find the *fons et origo* of the lofty contempt for "scientific experts" and of the Photographic Society of Great Britain which has since been the parrot cry of a handful of egotistical and disappointed photographers.

I am an old member of the Photographic Society of Great Britain, and I trust the time will never come when I shall see it go under, or merged into any new-fangled mushroom-growth brought into ephemeral existence by cliquism and self-seekers. The roll call of the Society is one that bears comparison in weight of artistic and scientific knowledge with any other photographic society in the world, and though up to a recent period that Society has been inclined to regard somnolence and dignity as convertible terms, I think every impartial man will feel assured from its recent renaissance, that whatever ground it may have lost will be recovered, and that before long it will have reasserted its right to be considered in esteem, as well as in title, *the* Photographic Society of Great Britain. I hope, as I believe, that I shall not see the day when it will be otherwise.

Such being the case, good "Immature," your thrust at the Editor of this Journal for suggesting that the Society should appoint a committee to deal with the Exhibition and Medal Question smacks both of prejudice and of the precocious effrontery of youth. To call the Society "dead" and an "abstraction" is a juvenile exaggeration at which those who know anything about the Society just now will smile. Again, the same writer, in falling foul of some remarks in the article on "Recent Exhibitions," seems to be rather disappointed that it did not settle the whole vexed question to everybody's entire satisfaction within the space of about a column. His own remarks, by the way, are singularly deficient of suggestions, practicable or otherwise. Destructive criticism, you see, is so much easier than the constructive variety. As to the whole question of exhibitions and the awards: I am not much interested in it; but for the sake of impartiality I should think it would be wiser if Judges and exhibitors had less to say in the matter than is the case.

What is this projected new photographic society about which these mysterious paragraphs are appearing in the photographic press just now? Surely the originators, whoever they may be, might communicate a few details to a wondering and mystified public. As I see some prominence is to be given to the usual club comforts, I suppose the promoters are jealous of that admirable body the Camera Club, and are seeking to run a cheaper show on beer-and-billiard lines, with a little photography thrown in as a sort of clarifying *raison-d'être*. I myself don't think there is any room for a new club, or institute, or society, or whatever this affair is likely to be called. London is well supplied enough with photographic societies as it is, without increasing the number. Far better let the promoters join existing institutions, and seek to strengthen them, rather than court contumely by bringing a new body to life which must be foredoomed to an early and ignominious demise. But, at any rate, why all this secrecy?

A recent correspondent was told that iridescent markings round the edges of gelatine plates are due to the plates being old or stale. Not always. I once had a few dozen plates direct from a maker which had only been made ten days, and they gave about as fine a sample of iridescent marking as I had ever seen.

Let me, in concluding my "Jottings" for the year, wish all my readers—whether they be among the "flayed" or the "unflayed"—a merry Christmas and a happy New Year, in the most humane and agreeable meaning of the term. Cosmos.

NOTES ON THE NEW AMIDOL AND METOL DEVELOPERS.

[Journal of the Photographic Society of India.]

I lately received small supplies of these new developers, and, though I have not been able to examine them fully, the following short notes may be of interest.

Amidol appears in small crystals, with a peculiar grey, silvery appearance. It is readily soluble in water, but the solution quickly discolours in the air. It is only slightly soluble in alcohol, the solution turning a pale yellow colour. It is a form of di-amido-phenol with the formula $C_6H_3\overset{OH}{(NH_2)^2}$. Ferric chloride turns the solution a deep crimson. Bichromate of potash turns it a brownish red, and a precipitate is formed in standing. Bromine water turns it red, the colour fading very much on standing. Potash permanganate turns it a deep crimson, becoming brown and muddy after a time. Alkalies turn the solution green. With carbonate of lithia and ammonia the green colour darkened, and then gradually became a bright yellow, which afterwards darkened. I have not noticed any fluorescence in the solutions after development, as is the case with many of the new dry-plate developers.

The peculiarity of amidol as a developer is that it can be used without alkali; by itself it is only a very weak developer; with alkalies it gives weak images, very liable to stain; but in solution of 5 parts in 1000 of water, with 50 to 100 parts of sodium sulphite, it becomes a very energetic developer, giving good density and detail with very short exposures. According to Dr. Eder, the addition of sodium sulphite increases its activity, and the ordinary proportion may be doubled.

The formula recommended by the maker is—

Amidol	20
Sodium sulphite	200
Water	1000

Diluted with from 2 to 3 parts of water.

This, when freshly made up, is an excellent and powerful developer

The solutions, however, whether concentrated or dilute, darken and lose their efficiency and developing power. I think I have found what may be a remedy for this.

During the year I have been making observations of the behaviour of various developers when electrolysed in a voltameter with platinum or silver electrodes, and one of the earliest experiments with amidol was to test it in the voltameter with platinum electrodes, passing the current from two pint bichromate bottle cells through a solution made up as for developing. The E.M.F. of the two cells was about 4 volts, but was reduced to about 1·5 volts when passing through the solution in the voltameter. In twenty minutes 1·4 c.c. of hydrogen were given off from the cathode, which is rather below the average of other developers with the same battery. The anode became surrounded by a dense, deep yellow solution, but otherwise the liquid in the oxygen tube did not change colour. The cathode had a tendency to keep coated with bubbles of hydrogen, but the colour of the solution in the hydrogen tube was unchanged. At the conclusion of the experiment, the solution, which was slightly yellow, was put away in a bottle; and it was observed that, whereas some of the same developer which had been used and put away and also the stock solution became very much discoloured, this electrolysed solution remained quite clear and colourless. Moreover, whereas the dilute ordinary developer which had been kept six days was found to have entirely lost all power of developing, the electrolysed solution (A) which had been kept for four days was found to work with even somewhat more vigour than a fresh solution. Not only so, it retained its freedom from colour and its developing powers for some time longer, even after use, as noted further on.

In a second trial some discoloured stock developer was taken and diluted with three parts of water, and then electrolysed in the same voltameter with the current from 4 gravity Daniell cells. The strong solution had a deep orange-red colour, but on adding water it took a claret colour. The E.M.F. of the battery was about 4·4 volts, which was reduced in the voltameter to about 3·7 volts, the current being 12 milliampères, with a galvanometer resistance of 100 ohms. In this case the evolution of hydrogen was much brisker. In 10 minutes 1·2 c.c. of hydrogen were given off, in 20 minutes 2·6 c.c., and in 30 minutes 4·1 c.c. The solution in the hydrogen tube became quite decolourised, while that in the oxygen tube gradually took an orange colour. The colour of the solution generally remained of a claret colour; and when the tubes had been removed, the current was allowed to pass directly through the solution, and gas was given off fairly freely at both electrodes. At the conclusion of the experiment this solution was also bottled off, and gradually took a pale orange colour. It was used for developing nine days after electrolysis, and showed very strong developing powers. With a Steinheil antiplanet lens 7½ inches focus at about *f*-10, and two turns of a Thornton-Pickard shutter, a Wratten instantaneous plate was found to be greatly over-exposed; but a good negative was obtained when the aperture was reduced to about *f*-15, and the tension of the shutter increased to three turns. It was found, however, that the still older solution (A), electrolysed with the bichromate battery about three weeks previously, which had much less colour, had still stronger developing powers, *i.e.*, it gave a denser image. On the other hand, a fresh normal solution at 1 to 3, made from a discoloured stock solution that had been kept for about ten days (B), gave only very weak images under the same conditions of exposure, &c., even with a preliminary treatment of the plate with a saturated solution of carbonate of lithia.

There seems, therefore, no doubt of the beneficial effect of the electrolysing treatment, not only in increasing developing power, but in conferring keeping properties, and thereby greatly adding to the value of amidol as a developer, though it remains to be seen how the treatment can best be applied. I am not sufficiently acquainted with the chemistry of these new amido-phenol compounds to be able to say what the effect of the electrolysing action is, or what new and more permanent compound is produced. It would seem that there is some reducing action brought about with the evolution of hydrogen.

As it seemed desirable to ascertain whether there was any distinct relation between the developing power of these two developers (A) and (B), and the amount of hydrogen given off under electrolysis, they were electrolysed under as nearly as possible similar conditions, with a current from 4 gravity Daniell cells passing through the voltameter, platinum electrodes being used as before. The old electrolysed solution (A), with a current through the voltameter, of 3·25 to 2·8 volts and about 35 milliampères, gave off in 20 minutes 5 c.c. of hydrogen. The old stock solution, diluted with three parts of water, freshly mixed, as (B) was highly coloured and with the same battery, gave off in 20 minutes 4·4 c.c. of hydrogen; the E. M. F. through the voltameter being 3·25 to 3 volts, and the current 36 to 30 m.a., the resistance of the galvanometer being 10 ohms.

In the present stage of these voltametric experiments it would be premature to say that the strength of a developer varies in proportion to the amount of hydrogen given off by electrolysis; but in one case it was very markedly so with Edward's pyro-potash developer and a commercial pyro and ammonia developer. The current from 2-pint bichromate cells being passed through them for 20 minutes; with the former 2·3 c.c. of hydrogen were given off; while with the latter only ·55 c.c. were given off in the same time. The pyro-potash acted as a good developer, while the pyro and ammonia only yielded very faint images under the same conditions. The difficulty in carrying out experiments of this kind is to ensure similar conditions throughout, so that the results may be truly comparable. I hope, however, to bring forward this subject more fully at some future time after further experiment.

As far as I have been able to try amidol it certainly seems to have advantages, when used under the best conditions, of securing density and detail with a minimum of exposure, and will be useful for instantaneous work, interiors, and other poorly illuminated subjects. In using it, it will probably be best to add it dry to a solution of sodium sulphite at 10 per cent., just as required for immediate use, using more sulphite, if necessary, to increase the power of the developer.

Metol appears to be a salt (said to be hydrochlorate) of monomethyl-para-amido-meta-kresol. It is a white powder, quite soluble in water, the solution remaining colourless for an hour or so, but slowly turning yellow and brown. It is not very soluble in alcohol. Alkalies (ammonia and lithia carbonate) darken the watery solution to a deep maroon brown. Acids (sulphuric, nitric, and citric) show no visible change. Bromine water produces a pink tinge. With ferric perchloride the solution was only slightly yellow. Potassium bichromate darkens the solution immediately, and gives a muddy brown precipitate. Potassium permanganate gives a purple colour turning brown. The metol solution reduces nitrate of silver in solution very quickly in the form of a bright metallic powder, some silver being also deposited on the sides of the containing vessel. At first the deposit remains in suspension in the solution. Acetic acid does not prevent this reduction. The solution in both cases had a brownish pink tinge after precipitation of the silver. In some of these reactions peculiar odours were noticed, in some cases like phosphorus, in others, a faint floral smell, and in others, again, a druggy smell, something like jalap. Metol has the advantage over amidol that its solution with sulphite of soda remains perfectly colourless, and shows little tendency to change even in a half filled bottle, though it slowly takes a yellowish tinge. The mixed developer after use takes a pale yellow colour with a strong blue fluorescence.

With lithium carbonate I find it a very good developer, though not quite so powerful as amidol. With soda carbonate rather more density was obtainable, but I have not yet been able to give it a fair trial. Metol seems likely to produce good reversals with the thiocarbamides in dilute solution with a large proportion of alkali, and on the whole promises to be more generally useful than amidol. I hope to be able to report further about it next month.

COLONEL J. WATERHOUSE,
Assistant Surveyor-General of India.

ON SILVER HEMISULPHATE.

(American Journal of Science.)

THE existence of those substances which I described some years ago under the name of photosalts of silver,* necessarily implied the existence of the hemihaloids of silver also, as these latter entered into the composition of the photosalts. Similar inferences, though less definite, had long been drawn from the action of light on silver haloids. Two of these, the chloride and bromide, lost by the action of light their complete solubility in ammonia without becoming completely soluble in nitric acid. Evidently there was indicated an intermediate compound between the normal haloids and metallic silver. During the last ten or twelve years I have devoted much time to the attempt to isolate these lower compounds of silver, and to gain some certain knowledge as to the hemioxide, whose existence seemed almost a necessary inference from that of the hemihaloids. Some eight years ago I obtained a substance having all the properties which one would be disposed to ascribe to Ag_2Cl, and a large number of analyses made seemed to confirm the view. I hesitated, however, to publish a description of it, not feeling entirely certain that it might not be a mixture, as to which a concordance of the proportions found of Ag and Cl with theory gives no sufficient information. Since then M.

* See BRITISH JOURNAL OF PHOTOGRAPHY, pp. 330, 345, 472, 486, Vol. xxxiv.

Guntz has described a subchloride obtained by acting on silver hemifluoride with phosphorus pentachloride and a hemioxide derived from it. Up to the present time no combination of silver hemioxide with an oxyacid has been known.

Such a combination I have been able to obtain as a double salt of hemisulphate and normal sulphate containing one molecule of each. The new salt has a light bright brown colour, and exhibits a stability which, in view of its composition, is something remarkable. It has no tendency either to oxidation or to reduction. Nitric acid, unless very strong, has but little action upon it. Acid of 1·42 poured over it in large excess, and let stand for several days, gradually dissolves it completely, but the same acid diluted with two or three times its volume of water, has so little action that it forms a convenient means of purification. On the other hand, ferrous sulphate, which instantly reduces argentic sulphate, has no action whatever on the new substance, even with several days' contact. Hot, strong sulphuric acid has no action. It might almost be expected that under its influence the argentous salt would gradually take up oxygen and be converted into argentic sulphate. But a specimen which was covered with a large excess of undiluted sulphuric acid in a flask, and was kept under boiling water for ten hours, was not altered thereby. Another strong proof of its stability is found in its resistance to heat.

The application of heat produces a somewhat curious succession of colours. The terra cotta or warm brown shade of the moist substance changes by drying above 100° to pale lilac, at 165°–170° it becomes greyish, at a somewhat higher temperature, yellowish green. Considerably below red heat it acquires a fine ruby red colour. In cooling, this red darkens almost to black, then becomes lighter again, and when cold the colour is light olive-green. The changes are repeated as often as the substance is heated and cooled. No sulphuric acid vapours are disengaged even at a low red heat.

It was mentioned in a previous paper that when silver nitrate is reduced by solutions of phosphorus or hypophosphorous acid, or by acidified solutions of their alkaline salts, transient colourations were produced that seemed to suggest the presence of some form of allotropic silver. Since that paper was published this reaction has been taken up for further study. It soon appeared that when the silver salt was treated with a solution of alkaline hypophosphite, acidified with sulphuric acid, the result obtained was entirely different from that which presented itself under any other circumstances. It became clear that sulphuric acid did not act solely by setting free the hypophosphorous acid, but also acted on the silver with formation of a double sulphate.

A remarkable though limited analogy here presents itself between the substance just described and the photosalts of silver. The silver hemihaloids are very unstable substances, but acquire stability by uniting with the normal haloids. In the same way the hemisulphate, which is not known to be capable of separate existence, becomes perfectly stable by union with the normal sulphate. The limitation to this analogy lies in the fact that the last-mentioned combination occurs in definite proportions, which does not seem to be the case with the halogen compounds.

The new substance, then, is formed by the joint action of sulphuric and hypophosphorous acid on a silver salt. Hypophosphorous acid has but little action on silver sulphate already precipitated, but it is different when the silver sulphate is formed in presence of hypophosphorous acid.

Several silver salts may be used. I have at different times employed the nitrate, phosphate, and carbonate. The latter is perhaps the best, because the action with the nitrate is too rapid, and with the phosphate too slow, and for other reasons.

A weighed quantity of silver nitrate is precipitated with an excess of alkaline carbonate and washed. The carbonate, as well as all other reagents employed, must be absolutely free from chlorides, otherwise the product becomes contaminated with silver chloride which cannot be removed. The silver carbonate is then treated with a solution of alkaline hypophosphite acidified with sulphuric acid. All the alkaline hypophosphite of commerce contains much more than a trace of chloride: this is best got rid of by adding to its solution a little solution of silver nitrate, stirring well at intervals, letting stand for twenty-four hours, and filtering. This filtrate, with addition of sulphuric acid, is to be poured over the moist silver carbonate, and constantly stirred. The reaction is complete in twenty or twenty-five minutes, when a bluish-black film of reduced silver begins to form on the surface. Further action is then cut short by neutralising the liquid with alkaline carbonate. The precipitate is next to be washed several times by decantation. Very pure distilled water is, of course, needed throughout.

Convenient proportions are: forty grammes silver nitrate precipitated with excess of alkaline carbonate. Of sodium hypophosphite, 100 grammes, dissolved in 650 c.c. of water, are treated with a little silver nitrate, and after standing and filtering, four c.c. of sulphuric acid are to be added and the liquid poured over the silver carbonate. After a few minutes, six c.c. more of sulphuric acid, diluted with a little water, are added by degrees. With this second quantity of sulphuric acid the characteristic reddish-brown colour of the substance first appears.

This process may be varied by precipitating with disodic phosphate (which must be perfectly free from chloride) instead of alkaline carbonate. The action is much slower, about twenty-four hours being needed. Silver nitrate itself may be used, but the action is too rapid and the product is less in quantity.

The crude product obtained in either way is to be purified with nitric acid. Acid of 1·42 is diluted with three times its volume of water, and of this dilute acid a quantity is taken about double in volume to that of the precipitate and of the water left after decanting closely. After a time some effervescence takes place, but the mixture does not become warm. After standing for three or four hours over the precipitate, it is to be poured off and the precipitate washed. This treatment with acid is applied three times: the first removes a good deal of silver, the second a little, the third a trace. Each time the acid is left three or four hours in contact. The product is then washed by pouring on it a large quantity of boiling water. This is repeated four or five times, each time (except the first) placing the vessel in a water bath kept at 100° C. for several hours.

The product is either dried in the air or (for analysis) at 100° C. It forms a bright brown substance, permanent in the air, changing to violet when kept for some time at 160° C. It has the peculiarity that when water is poured on it, it makes a sharp hissing noise. This takes place with the air-dried substance as well as that dried at higher temperatures, and as much with the former as with the latter.

The substance after purification has about one-half the weight of the silver nitrate taken.

These proportions and this mode of operating are those that I have found to give the best result. But the substance is formed under a great variety of conditions. It seems impossible to bring a silver salt in contact with alkaline hypophosphite acidified with sulphuric acid without producing more or less of it. Its presence is often completely obscured by reduced silver. But a mass that looks perfectly black and might be supposed to contain nothing but metallic silver will leave, when treated with nitric acid, a bright brown residue of the double sulphate. We have here, as before, an analogy with the photosalts. For it will often happen that a blackish mass, containing metallic silver, and mixed or combined silver chlorides, will, when treated with nitric acid, resolve itself into bright purple or rose-coloured photo-chloride.

M. Carey Lea.

(To be continued.)

HOW TO MAKE DRAWINGS FOR PROCESS BLOCKS.

While the subject of preparing photo-litho and photo-zinco plates for printing from, and of making process blocks of every kind, has for some years received great attention, comparatively little has been written upon the sister art of making drawings suitable for being interpreted by these processes.

And yet this art is one of high importance, and it is becoming more and more practised every day. All the cheap, and some of the more expensive, periodicals have their illustrations made by process work; and even the high-class monthly magazines, which not long since spent enormous sums upon the preparation of their wood engravings, have at length found it expedient to avail themselves of the great resources of photography. Speaking for myself, I have not during the past year made a single drawing that has been engraved by the old and still admirable process on wood, but all of them have been done by reproduction on zinc, both in lines and in washes, the one to imitate ordinary woodcuts, and the other that of fine wash drawings in half-tones.

For a long time the Americans held, in public estimation, the supremacy in delicacy of tone in work of the latter class, as witness, for instance, the magazines of the Harper's class; but since the introduction of process work and the grated screen, with a like quality of paper and good printing, the English magazines can now not only quite hold their own against such powerful competitors, but in some instances, perhaps rare as yet, can even surpass them.

But what I aim at present is to give in this article a few hints and directions how to convert a photograph into a line drawing which, when made into a printing block by process work, will yield prints which cannot be distinguished from an expensive wood engraving.

One must, of course, possess the ability to draw at least to some

extent, and above all things he must have a faculty for tracing with accuracy, else will he be in danger of losing the likeness and expression when drawing a portrait. The hair, drapery, and general surroundings are of comparative unimportance, and a clever artist will convey much of these by a few touches. If one examines the portraits of public men that are prepared for newspaper illustration, he will not fail to notice how much is left to the imagination to supply, while at the same time the characteristic features of the original are readily recognisable. In landscape work this is of less consequence; what is here necessary is to preserve the salient features of a scene without crowding too much into the sketch, and omitting or altering whatever is detrimental to artistic effect, such as badly placed trees or cattle.

There are two ways by which photographs may be converted into line drawings. The first is by special printing, taking care that it is not toned with gold in the usual way, but only fixed. Instead of albumenised paper, it is far better to use plain salted paper, a quantity of which may be prepared at one time, as it will keep good for a long period. This may be done by immersing it in water containing common salt dissolved in it in the proportion of about half an ounce to the pint. Some use chloride of ammonium instead of salt, but there does not appear to be much difference in the result. It should then be hung up to dry, and when quite dry placed in a portfolio for further use. To sensitise this paper, a sheet should be laid upon a piece of flat board or glass, and brushed or sponged over with a forty-five grains to the ounce solution of nitrate of silver in distilled water. There must be no metal about the brush, if such be employed in applying the silver. A few drops poured at the upper end of the sheet, which must in this case be held in a sloping direction, can be spread evenly by means of a glass rod; but, if a dozen sheets are to be sensitised at a time, it is better to pour the silver into a flat, square dish, and float the paper, smoother side down, on it for about two minutes, and then hang it up to dry. This must be done either in a room having deep yellow blinds, or in the evening by candle light. The paper is printed in the ordinary photographic printing frame until it is very dark, and the print is then washed in two changes of water, and fixed in hyposulphite of soda, one ounce to six of water. This will greatly reduce the vigour of the print. It should remain in this eight or ten minutes, and then be well washed in water. When dry it should be flattened by a smoothing iron, and then pasted by the corners to a Bristol board for convenience in handling. It is now ready for being drawn upon.

The ink for drawing is of the highest importance; and, as this applies to every system of process work, it is well to say a few words about it. It must be waterproof, and have such a degree of blackness that the faintest touch of a crow quill or a camel's-hair pencil will tell in the after-operations. That which is preferred by many process artists is the finest quality of Indian ink rubbed up in water to perfect smoothness. The water should be pure and made warm. The dish in which this is done ought to be heated until it feels unpleasant when the back of the hand is pressed against it. I have said that the water should be pure, but it should also be saturated before warming with bichromate of potash, which, as every photographer knows, will render the ink insoluble after drying. If liquid Indian ink, which is sold by artist's colourmen ready in a fluid form, is used, the bichromate should be added to it. When drawing with ink made in the manner directed it is the delicate, fine lines that require attention. They must be firm and black, or of a brownish-black colour—which does not matter. The stronger lines take care of themselves. For myself, I prefer Stephens' ebony stain, which can be got in sixpenny or shilling bottles.

The next thing is the selection of a suitable pen (for I will suppose that the draughtsman in making his first attempts uses a pen instead of a hair pencil). Joseph Gillott makes a variety of artists' pens, suitable for every class of work. If this is to be very fine, his No. 290 will serve the purpose. His crow quill No. 659 is also recommended by a high authority. A bolder pen may be used if the photograph is of large size and has to be eventually reduced to a fourth or sixth of its dimensions, for, as I shall afterwards show, many process blocks are from drawings which, for freedom of handling, are made more than four times the size actually required. But at present I am supposing that the finished block is of the same size as the drawing. I prefer for all-round work Mitchell's F pen, which I find is very easy to work with.

In drawing over the photograph cabinet size, which I will assume to be the head and bust of a gentleman, attention must be paid that nothing is omitted, and the direction of the lines must be studied from a good engraving.

The drawing being finished, the next thing is to discharge the photograph which has served as a base for the tracing. Having unfastened it from the Bristol board to which it was attached by the corners, and ascertained that it is quite dry, place the photograph in the daylight for a few minutes if the light has not had access to it during the drawing. This renders the ink quite insoluble. Next immerse it in a saturated solution of corrosive sublimate (bichloride of mercury), which in a very few minutes will be found to have acted on the photograph with such power as to have caused it to disappear entirely, leaving only your drawing visible. Chemists tells us that the photograph is not really dissolved away, but is only bleached the same colour as the paper. But it has disappeared from view. The drawing is now washed in pure water which is free from any alkali.

Comparison must now be made between the pen-and-ink drawing and another photograph of the subject, which should be taken as a reference. A beginner in this art will possibly discover that he has omitted some important feature, not observed while the photograph still remained upon the paper, but this can only arise from carelessness, and will probably not occur a second time. He may, perhaps, also discover that, from a like cause, he has altered the likeness or expression; but much of this latter is capable of being remedied by the application of Chinese white to stop out offending lines, and re-touching them with black ink.

A second way by which photographs may be converted into line drawings is by superposing on the photograph a sheet of thin woven paper, which has been rendered temporarily transparent by brushing it over with benzole in which Canada balsam is dissolved, and making a tracing precisely in the way previously described. This tracing paper should be attached to the photograph by the upper end. It has this advantage over the other, that it enables you to judge of your progress by inserting a sheet of white paper between the photograph and the tracing, so that an examination can be made at as frequent intervals as you desire. When the tracing has been accomplished, the paper is restored to its original white state by a fresh application of pure benzole, which dissolves out the Canada balsam. Castor oil, wax, and a number of other substances may be applied to paper to render it temporarily transparent, methylated alcohol, or any other solvent of the substance employed, serving to restore the purity of the paper.

A. J. Gough.

WORK WITH A HAND CAMERA.

Before the last meeting of the Putney Photographic Society Mr. Henry Crouch deputised for Mr. Dresser on this subject from notes supplied by the latter gentleman, and supplemented by his own experiences.

Mr. Crouch said that there could be little doubt but that the "ordinary" cameras were being gradually superseded by the hand camera, and that sooner or later the former would be a thing of the past. There were several reasons why this should be so, but the two chief were the improvements in the hand cameras and that plates were now made of such greatly increased sensitiveness that sufficient exposure could be obtained for snap-shots even in what would quite recently have been considered too dull a light. With regard to the cameras, every year showed a marked alteration for the better. Attention had been successfully given to the lens, shutter, and changing mechanism, and extra movements had been added, such as focussing, rising front, and swing-back. Hand cameras might be divided, broadly, into two classes, viz., magazine and those where the ordinary dark slides were used. Each system possessed advantages peculiar to itself, and it was a matter of individual opinion or special requirements which determined the question which camera was the most suitable. No camera should be expected to meet all wants. Some people desired to do very quick work; to them a magazine camera would offer advantages. Others wished to get the best results under varying conditions; for such the double backs or roll-holder would be preferable. For all-round work he had personally no preference, but thought that good and artistic work could be done with any good magazine or double-back camera, if workers would only take the trouble to make themselves acquainted with the mechanism and the extent and limitations of the power of their camera. Mr. Dresser had successfully worked the rollable film, and this method had the great advantage of compactness, lightness, and ease of changing; but it would appear, from general practice of average workers, that these advantages were not unfrequently considered to be more than counterbalanced by the subsequent trouble and uncertainty in development, &c.

Mr. Crouch then proceeded to deal in detail with the main parts of the hand camera, commencing with the lens. He said that, in hand cameras, the mistake was often made of using an inferior lens; in fact, one that no serious photographer would dream of placing on his ordinary camera. This was all the more inexplicable, when it must be obvious that the conditions of successful work with a hand camera were far more difficult, and required higher optical qualities in the lens than were generally found necessary in ordinary work. In order to obtain a suitable extent of view, and to be able to take in objects fairly near as well as at a distance, it was necessary that the lens should be of a comparatively short focus. For a quarter-plate, Mr. Dresser used, by preference, one of four and a quarter inches focus. Mr. Crouch personally preferred one of about five inches, but it might be laid down as a rule that the focus should be

between four and a quarter inches and five and three quarter inches, and certainly not more than six inches; if more than six inches, the chief objects within twenty-five feet or thirty feet would be out of proportion to the plate, and successful photography of street scenes and subjects in any but very open views would be extremely difficult. As regarded aperture, he had made lenses working at *f*-5, but they were not to be recommended, except to the most expert workers, who would only use them at this aperture with the greatest discrimination; *f*-8 was, generally speaking, the largest aperture at which any lens would work satisfactorily, as regards covering power and depth of focus, and, as a rule, a smaller stop should be used if possible, so that, when the principal object is in focus, the foreground, as well as the distance, may be fairly sharp. As a large aperture required very much more judgment and experience in working than did a moderate one, of, say, *f*-11 or *f*-16, he recommended beginners to commence with the smaller, and only by slow degrees, and after careful study of results, to increase it. A rapid rectilinear lens was by no means necessary, and Mr. Crouch said that, for landscape, and, indeed, for nearly all subjects except architecture, a good single lens was preferable, as it undoubtedly gave pictures of greater brilliancy. This result was, he thought, to a great extent due to the fact that the diaphragm was placed in front of the lens, and therefore a larger quantity of light could enter than was possible when the diaphragm was placed between the combinations, as in lenses of the rapid rectilinear type. The single lens had also the advantage of being considerably cheaper, a really good one being about the same price as a rapid rectilinear of comparatively inferior quality. As a first-class lens was the first consideration in hand-camera work, he strongly urged every one who desired to do good work to see that his camera was fitted with as good a lens as he could afford to provide. As regarded shutters, there was an almost endless variety in the market. He thought a good one should work with certainty at from one-two-hundredth to two seconds, and the best place for it was near the diaphragm, or immediately in front of the plate, the latter being, theoretically, more correct; but, after careful comparison of results, he had come to the conclusion that there was practically little or no difference, but as the shutter working near the diaphragm could be more compactly arranged, and had several other advantages, he preferred it, on the whole, to other forms. It was necessary that all parts of the shutter should be very strongly made, so as to be able to resist the very considerable strains due to a high speed, and it should be as simple as possible, so as to be unaffected by small particles of dust and other vicissitudes, which he had known to seriously interfere with delicate mechanisms at the critical moment. For occasional work, Mr. Crouch advised a fixed-focus camera, but for those with leisure, and in constant practice, better work would be possible with the power of altering the focus; this would, however, probably mean many failures, until they were able to judge distances quickly and correctly. He had found finders a great nuisance, and quite unnecessary, and he strongly advised members to do without them; by practising pointing the camera, he ventured to assert that, in a very short time, they would acquire the necessary proficiency to get the subject properly on the plate, and the finder would not be missed. As to the proper way of holding the camera, he did not think that any one position would meet all requirements; for near objects, he held it in front of him, about four feet from the ground—sometimes considerably lower; for far objects, he held it higher. In this connexion he had found a rising front of great assistance, as a very slight rise or fall of the front was equivalent to altering the height of the camera several inches. Using the camera in this manner, without finders, he claimed to be able to get in exactly what he wanted with greater speed and ease, and with less trouble in keeping lines parallel and true. There were now so many good plates and films that it would be invidious to advise the use of any one, but it should be remembered that, for hand-camera work, a brand having an emulsion rich in silver was much more necessary than when slow exposures were given. His advice was, Having found a good brand of plates or films, and suitable developer, stick to them.

He regarded development as one of the chief means towards a good result. When a plate had had an exposure of only one-two-hundredth of a second, much experience and careful thought were necessary. The following formula had, in his hands given excellent results, viz.:—

Eikonogen	1 ounce,
Sulphite of soda	4 ounces,
Carbonate of potassium	1 ounce,
Carbonate of soda, or washing soda	1½ ounces,
Water	30 ,,

and any hydroquinone developer, one without *caustic* soda by preference. With very fast exposures, two parts eikonogen solution should be added to one part of the quinone, to begin with; if this does not act sufficiently quickly, pour it off and use the eikonogen alone, adding saturated solution of carbonate of potassium per ounce till the plate began to fog. Some plates would stand up to one drachm per ounce, and others would not stand any addition.

It would thus be seen that a strong developer should not be used to start with. Begin with a normal developer until the image is fairly out, and then strengthen until the plate will bear no more.

Perhaps a still better developer for general work, and lantern slides, bromide papers, and exposures from one-tenth to one-hundredth of a second is,

Rodinal	1 part.
Water	20 parts.

Should there be any difficulty in getting density, the developer should be poured off and hydroquinone used.

He, however, thought that the best developer for snap-shots would be found in amidol, but was unable to say so definitely, having had only two chances to try it. However, on those occasions he had obtained marvellous detail and density, using the following formula:—

No. 1.

Amidol	1 ounce.
Metabisulphite of potassium	1 ,,
Water	10 ounces.

No. 2, saturated solution of potassium; No. 3, ten per cent. solution of potassium bromide.

For use take, No. 1, 1 drachm; No. 2, 1 drachm; No. 3, 5 drops; water 1 ounce.

Should exposure have been very rapid, leave out No. 3; if necessary to increase density, add twenty to forty drops more of No. 2. The image would flash up at once, but the plate would not fog unless very much over-exposed. In cases of over-exposure, more bromide should be used, but developer should not be weakened by the addition of more water.

PHOTOGRAPHY IN SCOTLAND.

[Abstract of the President's Address to the Glasgow Photographic Association.]

I often think that, were Daguerre or Talbot to come back amongst us and to appear before the Glasgow Photographic Association, it would take us all our time to give them a respectable audience—respectable, that is, so far as numbers are concerned. Now, this is not as it should be. Surely a little enthusiasm should be forthcoming from the votaries of an art which has already accomplished so much in the past, and which bids fair to accomplish still more, and that in the near future. I know of no art which is better calculated to awaken enthusiasm than that of photography, and surely the members of the Glasgow Photographic Association will not be that exception which goes to prove the rule by a total apathy and indifference. The indifference of Glasgow—and here I refer to the amateur photographic element no less than to the professional—was very well shown in the poor representation which Glasgow made at the Edinburgh Convention held in July. Including myself, there were only five members of the two Glasgow Associations present. These five "good men and true" are all members of this Association, and only one has the distinguished honour of being a member of our contemporary; so that, practically, it amounts to this, that the Glasgow amateur photographer was conspicuous by his absence. Photography surely is a thing vastly superior to clique work and to an annual division of medals. The true enthusiasts of the art will be found interesting themselves more with the conquests gained and the immense strides year by year our art is making, than with the acquisition of metal trophies or parchment awards.

Speaking of the Convention reminds me that the next meeting is to be held in Plymouth, and the Glasgow Photographic Association has the honour of providing the Convention with its future President. Mr. George Mason, the President-elect, one of our members of Council, will worthily fill the post. Applying the rule of three, if five Glasgow men go to Edinburgh, forty miles off, how many will be found next summer going south, say, 800 miles. This conundrum may be made to replace the "missing word" competition now declared illegal. Our best congratulations are tendered, I am sure, by one and all to Mr. Mason in his capacity of President of the Photographic Convention of the United Kingdom. There have been now six Presidents in all, three of whom are Scotchmen—Taylor, Pringle, and last, though not by any means least, Mason.

No startling photographic discoveries have been brought forward during our summer recess. The introduction of the developer amidol is, perhaps, the feature of greatest interest. I do not know its true chemical composition; it is presumed to be what is known as amido-phenol. Here is the substance in question: It is closely allied to the developer rodinal, both being derivatives of phenol, better known as carbolic acid, the true chemical name of rodinal being para-amido-phenol. It is almost too soon to speak of its adaptability for negative work, but, for transparency pictures, it throws a very pleasing black deposit very similar to rodinal. I have made use of it myself in this direction, and will show, by means of the lantern, one or two slides produced by its means. It is invariably employed along with sodium sulphite. Since writing foregoing I find, at page 742 of The British Journal Photographic Almanac, the details of patent specification are given by J. Hauff, Feuerbach.

In connexion with what will come before us this season, I should have mentioned that I have a promise from Mr. F. E. Ives, of Philadelphia, that I shall have at an early date an opportunity of showing to members what has been accomplished in the way of colour reproduction by Ives' method.

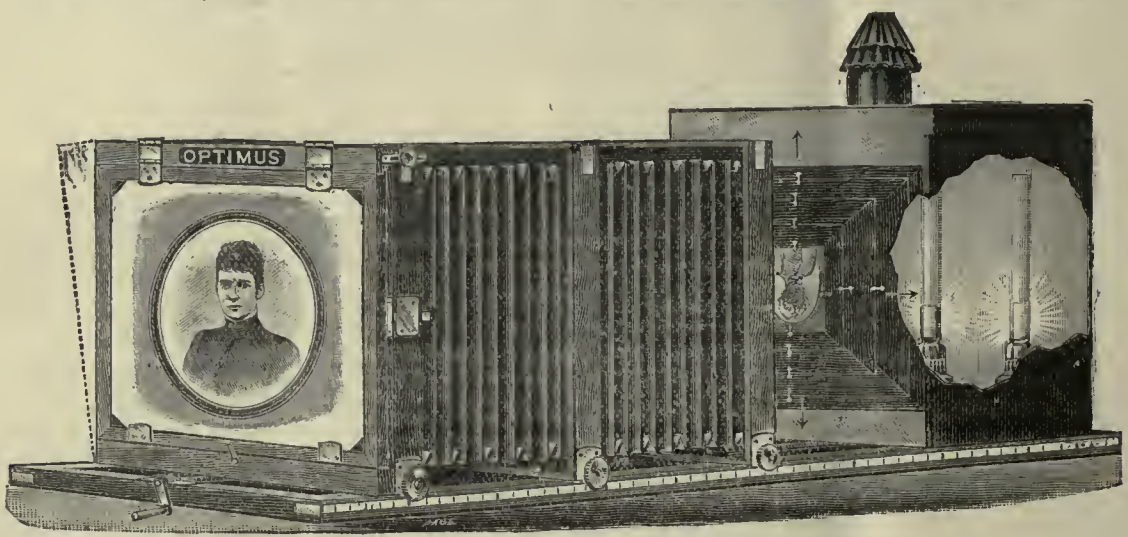
Another interesting night might be had with an arrangement of showing photographic transparencies in relief on the screen, a method having been discovered by Mr. J. Anderton, of Birmingham.

An advance in printing paper is the employment of what are known as printing-out papers, where gelatine replaces the now more or less discarded albumen. Gelatino-chloride paper, as it was formerly known, will certainly run albumen chloride very hard. The ease with which a highly enamelled surface can be obtained is one of its distinct advantages. Perhaps some of our professional friends will give a demonstration during the session and state their experiences. WM. LANG, JUN., F.C.S.

A CONVENIENT ENLARGING APPARATUS.

With a view to the photographer becoming his own enlarger, Messrs. Perken, Son, & Rayment have introduced an enlarging apparatus which fulfils the requirement in a singularly perfect manner. Its configuration is shown in the engraving.

It is adapted for enlarging either by daylight or artificial light. For the latter, there is an illuminating chamber at the rear, containing two



oil lamps, by which the opal, or ground glass plate behind the negative is uniformly and well lighted. For the former, this chamber is removed, and the end of the apparatus directed against the sky; hence this instrument may be used either by day or by night. The adjustments provide for any portion of the negative, from the corner to the centre, being brought opposite to the lens. The several moving parts have each a rack and pinion, so that they can be relatively adjusted one to the other. The baseboard is likewise furnished with a screw, which goes from end to end. When all the adjustments have been made, each movable part can be securely clamped. We think very highly of this apparatus, as it so well fulfils the requirement of enabling a professional photographer to make an enlargement himself when time does not admit of his sending it to the professional enlarger. The reader will already have deduced from the above that reductions from large negatives can be as easily effected as enlargements from small ones.

THAUMATROPIC EVOLUTION.

UNDER the title of An Electrical Wonder, there is now open in 425, Strand an exhibition of several of the renowned photographs of Herr Anschutz of animals in motion. They are seen in apparent actual motion, each subject being composed of a series photographed in rapid succession, and then shown while in rapid rotation by the well-known instrument known as the thaumatrope, the phenakistiscope, the wheel of life, or the zoopraxiscope. The present one, however, has been specially constructed to be illuminated by electricity. As these instruments have all been, at some period, described in these pages, nothing need here be said concerning the principle involved in their construction and the application of the persistence of vision. The attitudes assumed by men in jumping or horses in movement are most admirably displayed, and, judging from the great interest that was displayed over a year ago in the witnessing of similar animals in motion, shown by Mr. E. Muybridge before some of the learned societies, we can recommend a visit to those of Anschutz, in the certainty of the spectator being both amused and interested. Mr. A. Schwarz is the agent in this country for Anschutz's clever productions.

RETOUCHING WITH THE INCANDESCENT LIGHT.

[Photographic Times.]

THE dark weather and Christmas busy times are on us, and poor-light nights and mornings, together with occasional days of leaden sky, force the retoucher to concentrate effort, and make hay while the sun shines.

The terrible havoc which overworked or abused eyes play with the general health of men and women, is well known to physicians and oculists; and this abuse and overwork at this time of the year is not only frequent, but the rule. To a humanitarian, the wicked waste of human life spent at the retouching desk is appalling and utterly inexcusable.

Fortunately the progress of invention has made ready to our hands an apparatus which mitigates this extra waste, and, perhaps, would prevent it altogether if universally used. I refer to the incandescent electric light. No retouching stand, at this time of the year, should be without it; the cost is insignificant for both apparatus and current, while the steady light which it gives is a great relief to the wearied eyes struggling in vain to see with the aid of a mirror as reflector.

In my own practice I use a twenty-five candle-power lamp, and have a lot of slack wire so that I can place the light where I please: ordinarily it rests at one side of my retouching desk, ready to be moved at a moment's notice to its place, directly in front of the hole where I work, and about six inches away from it. A ground glass stands close in front, and another half-way between it and the negative, and the regular ground glass of the stand makes three thicknesses of that commodity. Although there is a little glare, I don't find it annoying. The whole is adjusted in a minute, and there is no loss of time. This glare can be avoided by using a thirty-two candle-power lamp, and placing it a little to one side, so that it is not directly in front; diffusing with a piece of ground glass close to the globe, and surrounding on all sides by white reflectors, gives an easy and agreeable light.

By interposing a plate flowed with collodion containing a little aniline violet, a good deal of the yellowness is avoided, and a soft easy, slightly greenish-coloured light results, which is pleasanter to many than the yellow of all small artificial lights.

The superiority of the incandescent light lies in its comparative freedom from heat and consequent danger of fire; its ease of application, for the lamp takes up so little room that it need not be moved from the stand; but most of all it is steady and constant, there being absolutely no flicker to weary the eyes, such as makes gaslight unbearable and kerosene lamps wearying. I have several times during the past two years worked all day with the light as described, and found myself little if any more tired than with daylight, and the work is of a more uniform character than is the case where negatives are retouched in a poor afternoon light, every negative retouched by the incandescent being fully up to the standard. R. W. HARRISON.

WE had the pleasure of a call the other day from Mr. Peter Mawdsley who is on a brief visit to this country from his adopted home at Rochester N.Y. Mr. Mawdsley had a great deal of interesting information to impart in regard to photography "on the other side."

Our Editorial Table.

Messrs. Cadett & Neall have sent us a sample of their "Lightning Plates," 130° (Hurter & Driffield). They are exceedingly rapid, and, allied with high sensitiveness, possess the good qualities of a first-class plate.

The Anschutz Tachyscope.

At the present moment, when the Anschutz Electric Tachyscope, the wonders of which are developable by dropping the omnipotent penny into the inevitable slot, seems likely to find public favour, it may not be unsafe to assume that the Tachyscope itself (which is in the hands of the Blackfriars Company, of Surrey-row) will achieve renewed success. It consists, as most of our readers know, of a series of reductions of instantaneous photographs of men and animals in various consecutive attitudes, so to speak, which are printed on strips of paper. These, when placed in a revolving circular receptacle, and viewed through small slits, convey a perfect impression of motion. Much amusement, and no little instruction, can be obtained from the Tachyscope, which should be highly appreciated at this time of the year.

"Photographs at the Pall Mall Exhibition."

The Photographic Publishing Company, 215, Shaftesbury-avenue, W.C.

Although somewhat late in appearance, we are glad to welcome this publication. It consists of several plate and other reproductions of pictures shown at the Photographic Society's Exhibition which the Editor, Mr. Charles W. Hastings—who also writes an appreciative notice of the photographs—has selected for illustration. The tones of some of the "Woodburygravures" are perhaps not the most suitable that could have been selected for the subjects, but with this exception the collection is very good. Mr. W. Bedford's *Norwich Anglers*, Mr. Benham's *Lions*, Mr. Burchett's *Love Letter*, Mr. Byrne's *A Grecian Girl*, Mr. Dresser's *Aylesford*, Colonel Gale's *East Country Quay*, Mr. Lord's *How's That*, Mr. Stevens' *Coleus and Begonias*, and Mr. Tagliaferro's *Uninvited Guest* are among the pictures reproduced in plate form, while there are several half-tone illustrations in the text of equal merit. The work is a most artistic *souvenir* of a memorable Exhibition.

PATENTS COMPLETED.

Improvements in or relating to Roll-holders for Photographic Films.

(A Communication by Frank A. Rownell, Rochester, County of Monroe, State of New York, United States of America.)

No. 625. Alfred Julius Boult, M.I.M.E., 323, High Holborn, Middlesex. *November 12, 1892.*

The present invention relates to the film-carrying and feeding devices of roll-holders for photographic film, and has for its object to improve particularly the construction and operation of the measuring and arresting devices for arresting the operation of the feeding devices after a certain quantity constituting preferably a single exposure has been wound forward or into a position to be exposed in the camera.

The casing may be adapted to be applied to the back of a photographic camera of any desired construction, and may be divided into two longitudinal compartments by means of a partition, to which is secured a film support or table having at one edge an antifriction roller, while the other edge is rounded so that the film may be moved from one compartment over the table or support and back to the other without undue friction, and may be held, while the exposure is being made, perfectly flat upon the support.

The flexible photographic film may be wound upon spools supported in bearings in boxes or receptacles adapted to be inserted into the compartments in the holder casing, and the outer end of the casing is closed by a cover plate secured in position by means of a screw adapted to be operated from the exterior of the casing, and engaging a nut secured to the partition piece, or other suitable fastening devices could be employed. The boxes containing the film spools are provided at one corner with a slit or opening for the passage of the film into and out of the boxes. The ends of the spools are provided with slots or the entrance of ribs or projections on the winding and measuring devices, as will be hereafter explained.

The film-winding or feeding devices consist, in the present instance, of an arbour journalled in the casing end, and having on its inner end a rib or projection arranged to enter the corresponding groove in the end of the spool, and provided on its outer end with an operating handle, and secured in place by a plate, and also provided with the usual ratchet mechanism for preventing the reverse movement of arbour. Arranged at the corresponding end of the other longitudinal compartment in the casing is an arbour journalled in a plate and provided on its inner end with a rib or flange arranged to enter the slot in the end of the spool located in the compartment. It will be understood that the receptacle containing the spool of unexposed film is inserted in one compartment, and the end of the spool engaged with its appropriate arbour, and the film extended over the support and attached by any suitable means to the roller in the receptacle in the other compartment, which roller is engaged with the key or handle, so that the revolution of the arbour can be seen from the exterior of the holder.

In practice I make the breadth of the support approximately equal to the circumference of the spool when containing half its normal quantity of film, so that each revolution of the supply spool will indicate that approximately the quantity of film necessary for a single exposure has been moved forward over the support; therefore, if the supply spool is arrested and the film is marked at the edge of the support at each revolution of the supply spool, the operator will not be in any danger of winding forward more than the amount of film necessary for a single exposure, and he will be enabled, by means of the designating mark, to readily sever the film into the separate exposures. Upon the outer side of the plate is arranged a locking detent or lever secured to an arbour journalled in the plate, and extending around a collar secured to the arbour, the latter having on its outer end a milled head. The collar is provided with a recess, and the locking detent with a projection adapted to enter the said recess and arrest the rotation of the arbour and spool. At the forward or free end of the detent is a screw or pin extending through a slot in the plate, and operated upon by a spring, which, in turn, is coiled around a screw, its outer end passing through a lug secured to the under side of the plate. The tendency of this spring is to move the detent in a direction to cause the engagement of the projection with the recess, and if this projection rested normally on the periphery of the collar the engagement would be effected and the supply spool arrested at each revolution; but, when the operator desired to release the locking mechanism in order to wind forward another exposure of film, the projection would immediately drop back into the recess and prevent the winding operation unless some means were provided for holding it out of engagement after being disengaged from the collar. In order to provide for this, and to hold the detent out of engagement until just before another revolution of the spool is made, I provide a retaining dog pivoted to the under side of the plate and provided with a slight notch, adapted to engage the pin on the end of the detent. A spring is passed around a screw, one end engaging a flange on a pawl and pressing the latter toward the arbour in a direction to cause the engagement of the notch with the pin. Arranged upon the arbour is another pin, adapted, when the arbour is rotated, to engage the retaining dog and move it in a direction to disengage the former pin and permit the projection on the lever to rest upon the collar. Journalled loosely upon the arbour is a ratchet counter disc having upon its face next the plate a series of figures indicating the number of exposures and visible one at a time through an aperture in the plate. This disc is prevented from backward rotation by the end of the spring which engages with it, constituting a pawl, and upon the pin attached to the detent is pivoted a pawl which is held in engagement with the wheel by a spring which engages with its heel beyond its pivot, and also moves the detent into engagement with the collar, so that, when the lever is moved by its operating handle in a direction to disengage the projection from the collar, the counter disc or ratchet wheel will be moved, one tooth showing another number through the aperture, and when the projection on the lever drops into the notch the pawl will move over the ratchet and engage the next succeeding tooth.

In order that the film may be properly marked after each exposure, so that it may be severed into separate negatives, I locate at one end of the film-support a small pivoted lever, having on its inner end a pin or projection adapted to perforate the film from the back when the lever is moved on its pivot, and extend the outer end of said lever through a perforation in the end of a link pivoted to the end of a lever rigidly secured to an arbour, the connexion being such that, when the locking detent is thrown into engagement by its spring, to arrest the spool and the arbour rotated, the lever is turned on its pivot and the pin passed through the film, marking the latter at the edge.

It will be understood that the lever may be pivoted at its middle, causing the marking to take place when the spool is arrested, or the location of the pivot could be so changed that by the release of the detent the marker could be caused to operate.

The operation of the device will now be readily understood. A receptacle containing a full spool of film, preferably having pieces of black paper secured to the ends of the film, one of which is attached to the spool, and the other extending out through a slot in the receptacle, is placed in its chamber, and the slot in the end of the spool is engaged with the rib on the arbour, and another receptacle having an empty spool therein is placed in the other chamber in the holder, the slot in its spool engaging with the rib of the wind-

ing arbour. A piece of paper being secured to this spool or roller is extended through a slot in the receptacle, led over the film support, and connected with the piece on the supply spool, then the cover plate is secured in position, and the winding arbour is turned until an exposure of film is drawn over the film support, the movement necessary for this being determined by the length of the paper on the outer end of the film on the supply spool. The film is now exposed in the camera in the usual manner, and it is assumed that the film spool was arrested when the first exposure was wound forward by the movement of the locking detent. At the same time the notch of the retaining dog engages the pin and holds the detent so that it will not immediately drop back into engagement with the notch in the collar. Then the winding arbour is turned, and a new exposure of film wound forward, and just before the rotation of the supply spool is completed the pin on the arbour engages the retaining dog and moves it into position, allowing the projection to rest on the periphery of the collar, so that on the continued movement of the film and the rotation of the supply spool the projection will drop into its notch and arrest the movement of the spool, after which the film can be stretched or strained slightly so as to cause it to lie flat on the support, the backward movement being prevented by the pawl.

When the detent is moved to release the spool, the pawl engaging the counter disc turns the latter one tooth, and displays the next succeeding number through the aperture in the plate, indicating the number of exposures, and enabling the operator to readily determine how many are left, the numbers on the counter disc corresponding to the number of exposures contained in a full spool.

When the arbour is engaged by the detent, the film-marking device will be operated from the latter in the manner previously described.

While it is not necessary, I prefer to employ the milled head on the supply spool, so that, if necessary, the operator may move the spool slightly to put the film under tension by rotating the spool backward in the event of its becoming loose from any cause. While it is desirable to provide a disc having a notch engaged by the detent, this is not essential, as a single tooth or projection would perform the function of the side of the notch from which the arbour moves, that could be engaged at the proper time by the projection or its equivalent.

This locking and counting device is cheap, readily applied, and has been found in practice admirably adapted for the purpose, and the measuring of the film into exposures by the rotation of the supply spool is found to answer all practical purposes, though, of course, where large rolls of film are employed, it is preferable to use a measuring roller, operated by the film. It will be understood that this invention could be as well applied to the measuring roll of roll-holders of the ordinary or any preferred construction.

The details may be varied without departing from the spirit of the invention.

Improvements in Magic Lantern Slides and in Substitutes for Stained Glass.

No. 3486. Henry Erskine and Charles Taylor, 63, North Frederick-street Glasgow, Lanarkshire.—*November* 12, 1892.

Our invention relates to improvements in magic lantern slides, and consists in making the slide of mica. The mica is first treated with a solution of collodion and ether, or purified isinglass, or fish glue, or silicate of soda, or transparent varnish, or size, or any of these solutions, or any combination of the same, or any transparent solution giving a transparent surface on the mica, and the drawings, designs, pictures, or words, are printed thereon in black ink, or black ink and transparent colours, or any colours, by hand or machine, letter-press printing, lithography, photography, photo-lithography, collotype, zincotype, photogravure, or any other cognate manner of producing printing or transferring any drawing, picture, or design, to be used as a magic lantern slide.

We might also substitute mica for stained-glass purposes, in which case it is treated, and the designs are painted or printed in a manner similar to the slides.

It is to be understood that the mica may be used without being first treated with any of the solutions already described.

Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, we declare that what we claim is :—1. Making magic lantern slides of mica in the manner substantially as described. 2. Treating mica so that it can be used as a substitute for stained glass, substantially as described.

Improvements in and connected with Photographic Cameras.

No. 941. Alexander Jeffrey and George Wishart, 140, West Nile-street, Glasgow, Lanarkshire.—*November* 19, 1892.

This invention comprises various improvements in photographic cameras and their accessories, which by means of them are rendered more convenient and satisfactory in use, whilst other advantages are also secured.

An improved camera, as made with some of the improvements, comprises a main frame fitted to receive the photographic plate or dark slide containing it, and having attached to it a pyramidal bellows, the smaller end of which has fixed to it a small board or lens frame, having the lens holder secured to it. The lens frame is jointed at the middles of its ends to small metal bars, each of which has one end jointed to what is termed the baseboard, and this baseboard is hinged to the main frame. The other ends of the small bars have fixed in them pins fitted to slide in slots in side bars, jointed to the main frame at the corners of the side opposite to that at which the baseboard is hinged. With this construction the lens frame can be moved inwards with the bellows close up to the main frame, or it can be drawn out to a suitable focussing distance, and in the latter position is held firm by the pins in the small bars engaging in notches in the side bars. The baseboard may be made of wood, in which case it is made of a U-shape instead of with a central hole ; or instead of such a board there may be substituted a pair of slotted side bars like those on the other side. Adjustable stops are provided to determine the precise angle to which the baseboard is to be opened, these consisting of round-headed screws in the frame and adjustable flat-headed screws in the baseboard. The small bars immediately carrying the lens frame are jointed to plates which are adjustable on the baseboard or side bars for the purpose of regulating the focal distance ; and instead of permanently fixed pins on the ends of the small bars there may be button-headed screws by means of which the small bars can be clamped in desired positions on the side bars. The attachment of the side bars to the main frame may also be made adjustable.

The main frame is made with the usual groove to receive the dark slide ; and when the dark slide is made for two plates, light is prevented from entering between the two parts by a rib of rubber or other suitable flexible material fixed in a groove in one part, and entering a groove in the other part, when the two parts are closed together.

Instead of the ordinary dark slide, we in some cases use a dark slide made of paper or other suitable thin material, and made just large enough to hold a single plate. This slide is made with a back and a front part, the bottom and side edges of the back part being doubled over and cemented at the corners to form grooves to receive the plate and the front part, which last is made with an extension or flap at its outer end, by means of which it is taken hold of to be drawn out for exposure when in the camera. A stop is provided to prevent the movable part being drawn out too far. A camera may be made with slide-grooves suitable for the new dark slide, in which case the camera can be made smaller for a given size of plate ; or an adapter frame may be provided to fit in the grooves of a camera of ordinary size, this adapter frame being made with grooves for receiving the new dark slide.

The new dark slide is made black, or otherwise impervious to actinic light. The cost of such slides will be very small, and sensitive plates may be put up in them at once by those who prepare such plates, and who can have their advertisements printed on the outsides of the slides.

Improvements in and relating to Photographic Apparatus.

No. 21,716. Emile Franck-Valery and Paul Frank-Valery, 42, Boulevard Bonne Nouvelle, Paris, France.—*November* 19, 1892.

This invention relates to a photographic apparatus having exteriorly the form of a leather case such as is carried by tourists on the shoulder-belt for containing their binocular or opera glass.

The improved apparatus comprises a box which serves as a base for the same and contains the object-glass, shutter, and focussing device. Upon this box are hinged the two sides of a leather case interiorly provided with a sheet of copper which is adapted to their shape, and serves to strengthen them. When the sides are put together they are held in the first place by a clasp similar to the ordinary clasps for albums, and in the second place by a leather cover, which does not differ from those used for binocular or opera-glass cases.

To further strengthen the aforesaid two sides and prevent the bending of the same, they are each provided interiorly with a mounting ; these two mountings having articulated to them two pairs of compasses which serve to keep the sides apart when they are opened.

The mountings have a hinge at their upper part, and carry two flexible bands of hardened steel, united by a third band of the same thickness, and placed at the same height as they.

These two bands have their other extremities united by a cross piece provided with velvet, but the latter is separated from the bands by small wedges, which keep it at the necessary distance from them for the passages of the frame.

The said two bands serve also for carrying pieces of fabric which form the camera obscura and are fixed at their other edges upon the said box and the two movable sides. The apparatus is carried by a shoulder belt traversing guides and attached to buckles.

One of the said buckles is attached to the cover for the focussing device, so that for using the latter it is sufficient to move away the belt with the hand in order to open the cover and look through the said device.

The shutter is simply of a sheet of metal pierced with a hole and fixed to a spring rod connected by a cord to a small exterior knob. For putting the shutter ready for action this knob, and by it the shutter plate, is pulled until a spring bolt enters a notch formed in the above-mentioned spring rod. For disengaging the shutter a pressure is exerted upon a knob provided for the purpose.

As this apparatus is also provided at its cover with a handle, it may also be carried in the hand.

When the case of this photographic apparatus is closed, the aforesaid bands are bent in the interior of the said case, and the compasses are closed. In this position nothing shows on the outside that the device is anything but a binocular or opera-glass case, the shoulder belt covering even the joint formed by the sides when they are placed together.

For using the apparatus, it is sufficient to remove first its cover, and then the clasp. Under the action of the bands forming springs the two sides are caused to move asunder, and when the compasses have been adjusted by passing with the hand into the interior of the chamber, the apparatus is quite open, the bands being under tension and ready to receive the frame.

This frame which may be of any suitable construction with a screen or otherwise, must have on three of its edges a groove so as to fit exactly upon the three bands. The said frame, with the screen below, is slid upon the two bands, and bears with its rear extremity against the third band, upon which it will fit.

As the cross piece is covered with velvet or the like, the screen can be operated without fear of light passing into the interior of the chamber.

Although the improved case employed is adapted for a photographic apparatus, it may serve for the reception of a binocular or opera glass. For this purpose two cushions are arranged at the top of the box hereinbefore mentioned. The binocular or opera glass is preferably covered with a leather bag so that it shall not be injured by the metallic parts of the case, and that the tourist shall be able to carry it easily with him without the photographic apparatus.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 15.—Mr. Thomas Bedding in the chair.

Mr. R. Child Bayley was elected a member.

A discussion took place as to the qualities of negatives yielded by commercial [illegible], Mr. J. A. Sinclair showing film negatives which were generally considered excellent.

Mr. COLE showed a negative having well-defined markings of a pictorial nature, and asked for the cause. It was suggested by Mr. DENENHAM that the markings might have been caused by tissue paper employed in packing; Mr. Cole, however, said that the plates were packed face to face.

The remainder of the evening was devoted to an exhibition of lantern slides.

Hackney Photographic Society.—December 13, Mr. F. Houghton presiding.—Mr. Hudson passed around a plate which had been very badly stained and which Mr. Beckett had cleared of iridescence by Farmer's reducer. Mr. Wire showed some flash-light work he had done with the use of a Todd-Forret lamp. Mr. R. Beckett passed around a photograph of himself which had been taken by flashlight by Mr. Nievsky with his combined apparatus. Mr. A. Barker showed a photograph he had taken of a spark from the Wimshurst electric machine. The Chairman handed round a broken lantern slide which was valuable to him, and asked for opinions as to how to repair it. Mr. Dear advised using Canada balsam to cement plain glass on to it, then, removing the cover, print a negative from it by contact in diffused light. Mr. R. Beckett advised using a roasting jack. Major Bruno's design of a hand camera was then explained by Mr. Beckett. It was made by Mr. Park, of Kingsland. The chief points were: a dark slide or roll-holder could be used, extending front, sliding focusing screen, swing-back, rising front, &c. Mr. Hudson showed his Thornton-Pickard shutter. He had a hole in the blind, but by using a small piece of court plaster it was successfully repaired. Mr. Walter Woodbury then gave a demonstration of the Paget print out lantern-slides and opal plates. A special frame was necessary to print opals, and he showed one the arms were bringing out, capable of taking any size upwards, from lantern size to half-plate. Lantern plates could be successfully printed in ordinary quarter-plate frame, as the density could easily be judged by looking through one side. Perfect contact was absolutely necessary with lantern slides, as otherwise fuzziness would be caused, a defect fatal to lantern slides. The lecturer then made some exposures with the platinotype lamp successfully. Ordinary toning bath can be used, but if combined bath is used the density must be a little greater. Several members took samples, and promised to bring up results next lantern night.

Elizabethan Photographic Society.—Mr. T. E. Freshwater, F.R.M.S., of London, gave a lantern-slide exhibition entitled *Rambles*, in the hall of Queen Elizabeth's School, Barnet, on December 15.—The views represented incidents of Her Majesty's jubilee celebration; scenes at Antwerp; and the habits of bees and the art of bee-keeping. Mr. T. Samuels, a vice-president of the Society, introduced the exhibitor to the audience, who highly appreciated his interesting entertainment. The series of bee slides were specially admired.

Croydon Camera Club.—Lantern Night, the President in the chair. It was announced that Mr. G. R. Whitehead resumed his secretarial duties.—The following showed slides: Messrs. Maclean, Oakley, Merton, Garden, Sladden, and Holland. Mr. Neeves also exhibited a large collection of prints, mainly taken at club excursions. The next meeting will be held on January 2, when a debate on *What is now the best printing process?* will be opened by the President. Several members have intimated their intention to advocate various processes and will show prints in illustration of their contentions.

Croydon Microscopical and Natural History Club (Photographic Section).—December 16, Lantern Evening, Society of Arts' loan series of Chicago slides.—The PRESIDENT (Mr. Lovett) read a short paper, which after briefly reviewing the history of the city, was devoted to an account of the World's Fair to be held in 1893. The slides included views of the city and the principal public buildings, sketches of the Exhibition buildings and grounds with photographs of them, from which, as they were almost finished, a good idea was obtained of the general appearance which the Exhibition would present when opened.

Greenwich Photographic Society.—December 7, Rev. Brooke Lambert in the chair.—Mr. T. E. FRESHWATER read a paper on *Photography among the Bees* (see next number). At its conclusion, in reply to a query from the Chairman, Mr. Freshwater said he did not think that modern methods of apiculture had at present affected the evolution of the bee. Replying to a further question, the lecturer pointed out that if not interfered with the bee is enabled to withdraw its sting by a corkscrew-like motion; but, if not allowed time for that after-insertion, the sting was usually left embedded in the wound. At the conclusion of Mr. Freshwater's lecture, a vote of thanks was passed to him. The Chairman announced that the Society's next meeting would take place in that building (Physical Lecture Hall, Royal Naval College) on Wednesday, January 4, 1893, at 8 p.m., when Mr. E. J. Wall would give a demonstration in *Isochromatic Photography*.

Derby Photographic Society.—December 13, A lecture and demonstration on the *Platinotype Process*, was given by Mr. S. G. B. WOLLASTON. Mr. R. Keene occupied the chair, and there was a large attendance.—In speaking of the treatment of platinotype paper, the lecturer emphasised the great importance of keeping it well stored and absolutely free from damp. With regard to development he might safely say that the hot-bath process was doomed, and was fast becoming superseded by the cold-bath method of development, which had been greatly improved of recent years, and possessed many points in superiority over its predecessor, which photographers had not been slow to recognise. Among other advantages mentioned were, that at any stage of the process development may be entirely stopped. It may also be retarded or localised, and over-exposure completely rectified by the aid of glycerine. These advantages, coupled with the results, which are highly artistic, placed this process in a foremost position amongst photographic sensitised papers. The lecturer illustrated his remarks with practical demonstrations of the results which can be obtained by the many different methods of treatment.

Brechin Photographic Association.—For the past year this Association has been engaged preparing slides to illustrate linen-manufacture. These are now completed, and on Wednesday evening, December 14, Mr. D. H. SAUNDERS, Dundee, gave a lecture entitled, *Linen and its Production*, in the City Hall. The lecture was illustrated by seventy slides prepared by the members of the Association, and was listened to by an audience of nearly one thousand persons. The lecturer was thoroughly at home in his subject, and slides of the processes of bygone days, such as the spinning and Pirn wheels, hand looms, &c., gave him an opportunity of referring to the past history of linen-manufacture in Scotland, with all its romantic incidents. The slides were considered to be most admirable illustrations of the processes, and the positions of the people at work very natural.

Glasgow Photographic Society.—December 15, Mr. William Lang, jun., F.C.S., President, in the chair.—Mr. Lang delivered his presidential address (see page 825). Dr. Paul Jeserich's paper, *Photography and its aid in the Detection of Crime*, with lantern illustrations followed. Mr. John Stuart showed a series of Zeiss lenses made of the new Jena glass. The Tachyscope, an instrument showing phases of motion by means of photography, was shown to members.

Photographic Society of Philadelphia.—November 9, the President (Mr. Joseph H. Burrows) in the chair.—It was also announced that the President had appointed the following Committee to conduct the Sixth Annual Photographic Exhibition under agreement with the Society of Amateur Photographers of New York and the Boston Camera Club: Robert S. Redfield, John G. Bullock, Charles R. Pancoast, Charles L. Mitchell, M.D., and Edmund Stirling. The exhibition will be held April 17-29, 1893, in the galleries of the Pennsylvania Academy of Fine Arts, and every effort will be made to make it the most interesting and successful of the series yet held. A number of photographic novelties were shown by Mr. Morris Earle, among which were celluloid trays of special construction and made in various colours, a transparent tray with a well at one end to hold the developer when tray was raised to examine the negative through the bottom. Dr. Mitchell showed negatives made under similar conditions with the Ross concentric lens and Ross portable lens, which afforded an opportunity for studying the comparative advantages of the two lenses for different classes of work.

Photographic Society of Japan.—November 4, Mr. G. Gilbert in the chair.—Mr. Tanaka showed some results of experiments in collotype. They were not quite perfect, but were remarkable as the results of first attempts in this difficult branch of photo-mechanical work, the more especially as Mr. Tanaka had worked entirely from written instructions. After trying various more or less complicated formulæ, he had settled on the following:—Bichromate of ammonium, 1 gramme; pure gelatine, 6 grammes; water, 70 c.c. He had found an admixture of isinglass, even in small quantities, the reverse of an advantage. Messrs. W. K. Burton and K. Ando showed the results of experiments in orthochromatic work. They had set themselves the task of getting photographs showing a brilliant pure scarlet, a bright but darkish blue, and a pure chrome yellow, in their true value. If these could be shown truly, all other colours could. They had succeeded best with a mixture of eosine and cyanine. Eosine was a strong sensitiser for the yellow and the green, cyanine for the red and the orange. The following formula was used:—Cyanine solution, 1 part in 1000, 1 part; eosine solution, 1 part in 1000, 1 part; ammonia 10 per cent. solution, 4 parts; water (distilled), 14 parts. The plates were bathed for two minutes and dried. Of course such plates need the extremest care in working. A yellow screen was used with plate-glass sides, enclosing a quarter of an inch thickness of the following solution:—Picric acid, 1 part; water, 500 parts. The intense but very light yellow colour of a picric acid solution seemed particularly well suited to orthochromatisation. With a denser solution than that mentioned it was possible

to overdo the orthochromatisation. The exposure needed was ten times that with the same plate untreated, but without any yellow screen. Mr. J. Favre-Brandt sent a paper on *Pinhole Photography* (see next number), along with samples of the work done and of the pinholes used. It was agreed that these samples were remarkably good. In fact, in some respects they were better than photographs taken with a lens, showing a pleasing softness. The exposures had been from one to about five minutes. The unusual excellence of these results was probably due to the great care with which the pinholes were prepared. They were in thin plates of nickel, were perfectly circular, in each case of the exact diameter that would give the finest definition with the focal length used, and the edges were delicately bevelled. Mr. Kajima Sebi showed a hand camera in the form of an opera glass. The arrangement, on the whole, was ingenious, but samples of work done by the camera were much under-exposed. The lens working at about one-sixteenth was far too slow for this kind of work, especially as the shutter was one that gave a bad coefficient of light. Further, there was no means of adjusting the focus. Mr. T. Kiyokawa presented the Society with a bottle of "retouching solution." This was to be applied to the plates whilst still wet, after fixing and washing. It was evidently an aqueous solution. Mr. Tanaka was asked to take the bottle with him, to try the solutions, and to report to the next meeting.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

LOCAL REDUCTION OF NEGATIVES.

To the EDITOR.

SIR,—Your article in last issue on "Local Reduction of Negatives" interested me, as I have had some experience in that way, and I am pleased to be able to give you a little "tip" as to the best material to use as an "accelerator" for the "rubbing-down" process.

Where only slight and delicate reduction is required, plain alcohol applied on a soft and *flat* pad is quite sufficient and *better* than the application of any assisting material, but it is too tedious to employ where a considerable amount of density or space has to be reduced, as in the case of a sky in a large landscape negative. I have tried finest ground and sifted cuttlefish and pumice-stone powders, but they are too coarse in grain, and more frequently result in scratches, which are almost hopeless to repair afterwards, and the remedy is worse than the disease; but, if you will experiment with *precipitated chalk*, I think you will find it admirable. There is great cutting power in it without any tendency to scratch, if the powder is kept carefully free from extraneous dust or grit whilst in use.

The rubbing pad (for small work wash-leather is best, and for larger surfaces an *old* silk pocket-handkerchief or the softest *undressed* muslin) should be fairly thick and flat, and as large in surface as the space to operate on will permit. It should be kept well soaked with the alcohol, and lightly touched on the powder occasionally so as to take up a small portion of it, and applied lightly to the plate in ever-varying *circular* sweeps, crossing each other to avoid unevenness in reduction. It is surprising what a quantity of "mud" is raised from the deposit of silver, but this can be readily removed when the work is completed by a good wash with clean muslin and alcohol, and the gelatine surface is left in quite a highly polished condition, too smooth, in fact, to have any tooth for the retouching pencil without some application of "medium" for that purpose. The process is somewhat like planing a surface of wood, the denser portions of the dry film stand up higher than the half-tones and shadows, and if the rubbing pad is kept as *flat as possible* these protuberances get the cutting action of the rubber, whilst the lower surfaces are slid over and missed, and therefore the reduction takes place more on the extreme high lights than any other part of the film.

It appears to be better for use than liquid reduction by chemical means, because, in such case, the solvent action is more marked upon the delicate deposits of shade detail and half-tones, and the picture suffers in "tonality" when applied all over the surface, and it is most difficult to confine liquid reducers to any particular parts of the surface. Personally, I should be glad to know of any process by which skies in landscape work could be *held back* from gaining too much density whilst developing. "Prevention is better than cure" in such matters, and some solution which would prevent agnition of undue density without stopping general development would be very convenient to apply to skies with a soft brush whilst the remainder of the plate is progressing to the desired density before fixing.

If you, or any readers of this, can give the hint, it would be acceptable to—Yours, &c., GEORGE BANKART.

December 19, 1892.

ORDINARY METHYLATED SPIRITS.

To the EDITOR.

SIR,—It may be interesting to some of your readers to know how to procure ordinary methylated spirit—*i.e.*, the old kind, without the addition of mineral naphtha. I therefore briefly sum up the correspondence, &c., with the authorities.

November 23.—Wrote to the Inland Revenue Office for a permit.

November 26.—Reply received, stating that the subject of my letter would be brought under the consideration of the Commissioners without delay.

November 30.—Received a visit from the district supervisor, who asked three questions, viz.—1. Where did I intend using the spirit? *Answer*—On the premises. 2. For what purpose? *Answer*—Making emulsion. 3. How much should I require annually? *Answer*—As small a quantity as one gallon. The supervisor stated that five gallons was the minimum, but possibly the Commissioners might allow me to have one gallon at a time.

December 6.—Received a permit for five gallons annually "for use in the preparation of emulsion for lantern slides."

December 7.—Wrote asking if I could have the five gallons, say one gallon at a time.

December 10.—Supervisor called with a book containing eight requisitions, stating that he should call on me four times a year to look at the book and see the amount of spirit in stock. Wrote once more to the Commissioners, asking if they would allow me to have one gallon at a time.

December 17. Received the Board's ultimatum, stating that ordinary methylated spirits cannot legally be obtained in quantities less than five gallons, and they were not prepared to recommend a change in the law relative to this minimum.

They further stated that their authority to receive such spirit remains in force so long as the authorised person occupies the same set of premises, and continues to use the spirit for the authorised purpose only.—I am, yours, &c. LEWIS MEDLAND.

Kimberley, North Finchley, December 19, 1892.

AMIDOL FOR LANTERN TRANSPARENCIES.

To the EDITOR.

SIR,—I have read with much interest an article by Mr. H. E. Davis in your ALMANAC on "Amidol for Lantern Transparencies," but would like to ask the author if the formula for No. 116 is correct. It stands thus:—

Amidol	1 part.
Metabisulphite of potash	3 parts.
Water to	60 ,,

Take of this half an ounce and add—

Bromide ammonium (ten per cent. solution)	1 ounce.
Carbonate Potassium ,, ,,	½ ,,
Water to	3 ounces.

Is not the amount of bromide ammonium too great, as it means about 5 : 1?—I am, yours, &c., E. HEALY.

10, *Endymion-terrace, Finsbury Park, N., December* 19.

PHOTOGRAPHY IN SOUTH AFRICA.

To the EDITOR.

SIR,—In your issue of the 21st of October, just received, appears a letter headed "Photography in South Africa."

I presume from the contents that Mr. Ellerbeck lives in Johannesburg and perhaps imagines that Johannesburg is South Africa. At any rate some of his statements are misleading when made under such a heading.

There are a great number of amateurs throughout the colony, indeed considering the white population, I think their number is quite as large in proportion as in most of the provincial towns of England.

Two or three statements I must take special exception to, viz., "There is very little beautiful scenery here," "Every one is confoundedly lazy," and "Detective cameras are never seen." To take the last first. I am sure I am within the mark when I say there are at least fifty hand cameras in frequent use in Cape Town. There are also a number in Kimberley, Port Elizabeth, Grahamstown, King William's Town, Queenstown, and East London to my own personal knowledge; and in all these towns (except, perhaps, the last two named, of which I am not quite sure) there are photographic clubs, whose membership consists almost entirely of amateurs.

I fancy a reference to our Ilford friends as to the number of quarter plates used in the Colony would confirm my statements.

Our Club album here and my own collection of views from different parts of the Colony completely refutes the statement as to there being very little beautiful scenery.

I am not personally acquainted with Johannesburg, so it may possibly be true of that portion of the Transvaal.

It may also be true that people are "confoundedly lazy" there. I am not in a position to confirm or deny it; certainly it is not true of the larger business towns in the Colony.

Neither does the statement as to scarcity of water affect the towns mentioned above, as they all have a very efficient water supply.

Then, as to the "cold winter days," my own experience of winter in the Colony (east and west) for some eighteen years has been that it corresponds with a *very mild* English spring, and, with the exception of

Kimberley and some of the more northern villages, we rarely get snow, except on the tops of the higher mountain ranges, and such a thing as ice (excepting manufactured) is a rare curiosity.—I am, yours, &c.,

HON. SECRETARY, *Cape Town Photographic Club.*

THE BENEVOLENT.

To the EDITOR.

SIR,—I enclose a brief report of the last meeting of the Benevolent Committee, and shall esteem it a favour if you will give me space to make a special appeal for subscriptions *before the end of the year*. I regret that, in sending the usual applications to old subscribers, I made the mistake (easily possible to a new hand) of stating that our financial year ended on February 28, 1893; out, though the annual meeting is held about that time, I find that the balance-sheet is made up to December 31.

The Association has been very well supported lately by the larger subscribers and donors, but we hope to have a great many more of the smaller annual subscriptions (minimum, half-a-crown). The money spent in relief will probably prove to be less than last winter; but there is every prospect of considerable calls during the next few months, which will, of course, not come into the next balance-sheet. The diminution in the relief paid in 1892 arises from two causes: (1) From the fact that in the first three months of the year there were no applications (though the latter half of the season is generally the busiest), and (2) from the fact that the Committee has been able to find work instead of money for some of the most pressing cases in the present season.

I hope to receive a general and generous response while the Christmas good-will warms the breasts of your readers.—I am, yours, &c.,

H. SNOWDEN WARD, *Hon. Sec.*

Memorial Hall, E.C., December 19, 1892.

FILLEBROOK ATHENÆUM PHOTOGRAPHIC EXHIBITION.

To the EDITOR.

SIR,—Will you kindly allow me through your columns to say, in reply to applications already received, that entry forms and rules of above Exhibition will be ready very shortly? In the meantime it may be of interest to mention that Messrs. F. P. Cembrano, jun., Walter L. Colls, and John A. Hodges have kindly promised to act as Judges; also that there will be no distinction made between amateurs and professionals, nor any division into classes, excepting a champion class for previously medalled exhibits.—I am, yours, &c., JOSEPH W. SPURGEON, *Hon. Sec.*

Drayton-road, Leytonstone, Essex, December, 17, 1892.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange half-plate camera with two slides for 5×4 camera and lens.—Address, J. BENNETT, 38, James-street, Swansea.

Wanted whole-plate Euryscope lens, in exchange for 15×12 view Ross and thirteen guinea Facile bicycle.—Address, E. J. LESTER, 7, Forest Hill-road, S.E.

Will exchange five dozen 12×10 hand-ground (new) opal plates (not sensitised) for lantern slides.—Address, J. REID, 1, Ford-street, Hyde-road, Manchester.

Wanted, a half-plate or whole-plate tourist's camera for gent.'s nine-carat gold ring, large easel, and dental vulcaniser.—Address, W. REYNOLDS, 9, Princes-street, Ulverston.

Will exchange a good modern whole-plate view lens, rotating stops, or other apparatus, for a good burnisher.—Address, W. E. SEATER, Albany Villa, Kentish-road, Belvedere, Kent.

Exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, 1883 to 1892, also five volumes, unbound, of the *Photographic News*, for backgrounds or accessories.—Address, J. ATKINS, 46, Stamford Hill, N.

Exchange new cottage piece and balustrade, in five pieces, in good condition, for cabinet, quick-acting, portrait, short-focus lens of good make.—Address, G. W. SHERMAN, Photographer, Great Yarmouth.

Wanted Eastman roll holder, 8½×6½; exchange postage-stamp camera with nine lenses, or Victoria camera with four lenses, or rapid rectilinear lens, sixteen-inch focus.—Address, F. EARL, 27, Foregate-street, Worcester.

Wanted a whole-plate portable camera with all movements, long extension and three double slides, in exchange for a first-class Wheeler & Wilson's lock-stitch family sewing machine, on nice stand and in perfect order.—Address, W. L. NASH, 27, Blackfriars-street, Edinburgh.

Exchange half-plate camera, double slide and stand, six-inch burnisher, Indian curtain for studio, and THE BRITISH JOURNAL OF PHOTOGRAPHY, three years, 1890-1892 to present time (all in perfect, good condition), for 12×10 outdoor camera and one or two double slides.—Address, E. KRAUSS, 162, King's-road, Reading.

Wanted, offers in exchange for the following:—THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACS for 1879, 1885, and 1892; *Photographic News Year-book* for 1868, 1885, 1890, and 1887; *Photography Annual*, 1891; *Studios of Europe*; *Retouching*, by Burrows & Coulton; *Zincography and Chemists and Druggists' Directory*.—Address, R. SHALLEY, 12, Park-road, Blackburn.

WEST LONDON PHOTOGRAPHIC SOCIETY.—December 27, Lantern.

PHOTOGRAPHIC CLUB.—December 28, Monthly Lantern Meeting. January 4, *Collodio-chloride Printing.*

MR. JAMES DOWNEY, Photographer, South Shields, has been placed on the magistracy of that borough.

PUTNEY PHOTOGRAPHIC SOCIETY.—January 9, Mr. Gotz on *Toning Gelatino-chloride Paper*, lecture and demonstration at eight p.m. at the Gymnasium, Charlwood-road.

IN reference to recent correspondence on the subject in our pages, we are informed that Mr. Shapoor N. Bhedwar, of Bombay, has withdrawn his resignation of membership of the Photographic Society of Great Britain.

CHICAGO EXHIBITION.—The Royal Commission for the Chicago Exhibition are arranging for a series of introductions to the different sections of the Catalogue of the British Section. Captain Abney will deal with the subject of "Photography." The general introduction to the Catalogue will be written by Sir Henry Trueman Wood, the Secretary to the Royal Commission.—*Athenæum.*

FOR the purpose of presenting the medals and diplomas awarded by the Judges in the photographic competition held in connexion with the recent Stanley Show at the Agricultural Hall, the Stanley Cycling Club are giving an invitation "Bohemian Musical Evening," at which ladies will be present, and will take place at the Wortley Hall, Seven Sisters-road, N., on Monday, January 9. In addition to the musical part of the programme the slides received in the competition will be shown in the lantern, and other interesting and amusing items are being arranged. Admission will be by tickets, which can be obtained by application to Mr. Herbert Smith, 29, Finsbury-pavement, or Mr. William Goddard, the Hon. Secretary of the Stanley C. C., 261, Seven Sisters-road, N.

PHOTOGRAPHERS' DINNER IN SHEFFIELD.—The first social gathering of professional photographers in Sheffield took place December 16. The chair was occupied by Mr. J. J. Sadler (Holmes, Sadler, & Holmes, Manchester), and Mr. MacIver, of Leeds, was in the vice-chair. One of the objects of the assembly was to signalise the establishment of a studio in the town (at the new *Independent* Offices) by Mr. Crosby, of Rotherham. He was highly spoken of by the Chairman, Mr. MacIver, and Edison, and the latter, in the course of his remarks, said he had gone up to Mr. Crosby's studio in the elevator, and found himself almost "shot into" the sitter's chair a few seconds after being in Fargate. Mr. Edison also spoke of the labours of the Chairman in the formation of the National Association of Professional Photographers. Mr. Crosby, in tendering thanks, said it had always been his endeavour to raise the status of his profession.

THE BENEVOLENT.—Meeting of committee held December 14, Mr. W. Bedford in the chair. An application for a loan of 8*l.* to pay arrears of rent and redeem lenses from pawn was considered. The Secretary had corresponded with the applicant, who said he could not give references, and, as the case seemed very urgent, had made a preliminary advance of 2*l.* on security of pawn tickets. The correspondence was carefully considered, the Secretary's action was confirmed, and he was instructed to redeem and forward the lenses, holding two pawn tickets for other goods as security, and to report to the applicant that the Benevolent could not grant further assistance without references. An application was read from a crippled photographer who had been previously assisted by the Association, and who now applied for a grant to redeem from pawn a lantern bought for him by the Association two years ago, which was his sole means of subsistence. An accident during the summer was the cause of his again getting into pecuniary straits. The sum asked for, 3*l.*, was granted as a loan. The Secretary reported that an application for immediate relief had been made to him at the office of the Association by a man evidently a photographer, who stated that he was penniless and ill, and was walking from London to his home in the provinces, over a hundred miles away. The Secretary had offered him a good meal and to pay his railway fare, an offer which he accepted with great profession of gratitude when he thought the money was going to be given him, but rejected with scorn and anger when he found that the Secretary intended to personally purchase the ticket and see him into the train. The resignation of Mr. H. D. Atkinson, whose removal from London prevented his continuing on the committee, was accepted with regret, and Mr. R. Child Bayley was elected in his place. Six new members were elected.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES. Meeting of Delegates, December 16, Mr. W. Bedford (Photographic Society of Great Britain) in the chair.—Two more Societies, the Hackney Photographic Society, and the Cheltenham Amateur Photographic Society, were announced as having become affiliated. Mr. Marchant (North Middlesex Photographic Society) brought forward the report of the sub-committee appointed to make recommendations with regard to the lectures on photogravure. The report contained a suggestion that a charge of one shilling for the course be made to members of affiliated Societies, and five shillings to outsiders, and that the secretaries of the various Societies should ascertain as nearly as possible how many of their members were likely to attend, so that arrangements could be made accordingly. Owing to circumstances that had transpired since the report was drawn up, the matter was referred back to the committee, who were instructed to arrange if possible to hold the lectures in the month of February, Friday being suggested as the most convenient day and one which would not clash with many photographic meetings. It was proposed by Mr. Steele (Leeds Photographic Society), seconded by Mr. Mackie (North London Photographic Society), and carried, that the whole question of the lectures should now be left in the hands of the sub-committee to carry the matter through. Mr. Steele (Leeds Photographic Society) and Mr. Walker (Leeds Photographic Society) gave particulars of a lecture on photogravure delivered in Leeds; the former also suggested that it should be strongly urged upon the various Societies that they should provide a set of lantern slides for circulation. His Society had taken the lead in this matter, although hostile critics had styled them fossilised, and he was rather surprised that some of the younger Societies had not taken the matter up. He trusted that no opportunities would be lost of appealing to the secretaries to bring this matter up.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

A. R. D.—See leading article, p. 49 of present volume.

C. H. OAKDEN.—Received. Thanks. We have had no further communication.

P. A. T.—Your trouble is like that of many others just now. See sub-leaders on the subject in the present issue. So far as we can see, these will meet your case.

J. H. AINLY, of 426, London-road, Lowfields, Sheffield, desires to communicate with Mr. Noel B. Kenealy, who last week wrote us concerning collodion preservative processes.

E. A. SHIRAFS.—Procure the *Autotype Manual* (the Autotype Company, 74, New Oxford-street) and study the numerous articles that have appeared in this JOURNAL on carbon printing.

J. NICHOLSON.—After applying French chalk to the glass in the usual way, coat it with collodion, immerse in a dish of water to remove the ether and alcohol, and then squeegee down the wet print.

J. SHUTER.—The glass can be coloured by varnishing it with negative varnish in which a suitable colour has been dissolved. A large proportion of the coal-tar colours are soluble in alcohol. Any of these will serve the purpose.

PYRO.—Whether you would have a legal remedy would, in our opinion, depend upon the nature of the correspondence that passed before the despatch of the telegram. On such meagre *data* as that which you supply it is impossible for us to advise you.

A. Y. E.—If space will allow, do not have the studio less than thirty feet long. This will permit of full-length portraits to be taken in tolerably good perspective. A provision may also, with advantage, be made for taking the camera outside, at the end, when groups have to be taken.

W. ALBERT.—In making up a solution of nitrate of silver, distilled water should always be used. The milkiness you speak of is caused by the sodium chloride in the water reacting with the silver nitrate to form a precipitate of silver chloride. Procure a manual of elementary chemistry.

J. KIRK.—1. Unless the paper is Hollingworth's make, we do not know whose it is. Any dealer in artists' materials will, however, supply it to order. Or, if a few reams at a time can be taken, it may be obtained through some of the wholesale stationers. 2. There is a shop near the bottom of Fleet-street where we have seen the things exhibited for sale.

JUNO writes: "Some say that prints ought to be washed for twelve hours at least, others say they can be equally as well washed in three or four hours. Which is right?"—All will depend upon the "washing." With proper treatment a print can be as perfectly freed from hypo, provided it is perfectly fixed, in an hour or less, as it can be with twenty-four hours' merely soaking, with an occasional change of water.

R. T. SCOTT asks what prospect a good photographer and retoucher would have in Australia?—Australia is a large place; but, so far as our knowledge goes and that obtained from correspondents, all the large towns are well supplied with photographers, and competition is as keen there, both as regards quality and price, as it is here. Perhaps some reader may be able to supply more definite information than this.

JAS. MARSHALL.—1. The design of the studio would do very well, but the ridge should certainly not be lower; indeed, it would be better if a foot higher, and it might with advantage be six inches higher at the eaves. 2. The lenses of the firm named have an excellent reputation. 3. You will find instructions for making a camera bellows in an article on the subject by Mr. J. T. Hackett in a recent volume of the ALMANAC.

S. W. J. writes: "I wish to take the meet of one of the hounds here the week after next. Of course I shall use a hand camera. Can you tell me what plates to use, and what speed to set the shutter at? Its quickest rate is one-hundredth of a second."—This is a question impossible to answer. The only advice we can offer at this season is, Use the quickest plates obtainable that suit your working, and adjust the speed of the shutter to the light, whatever it may happen to be at the time.

BEAUCHAMP writes:—"Will you inform me if you think that by advertising in your paper I could get a situation in a photographic establishment, where, in return for services rendered, I could be taught retouching. I may mention that I am an amateur photographer (age forty-one), and want to get an insight into the trade so as to commence business myself as soon as possible?"—We should think that there is a possibility of a photographer being willing to impart the necessary tuition in exchange for equivalent value in services.

R. MCKENNON.—It is quite a matter of agreement between party and party; but, if the agreement is made too one-sided, it will not hold good in a Court of Equity. We should say that an agreement to the effect that an operator on leaving the service of his employer was not to enter the service of another photographer, or commence business on his own account in Scotland or the border counties, would certainly not be valid in a Court of Law. Such an agreement might hold good if confined to a single town, and, if the consideration were in accordance, to perhaps to one or two counties. Better consult a solicitor.

A. R. SPENCER.—There is nothing in your communication but what is well known. Celluloid is a highly electrical substance when dry. The manufacturers of the material are fully aware of this.

ZENO.—Evidently you are a novice, and are not fully cognisant of what qualifications are requisite in an operator for a photographic studio. The simple fact that you are "fully up to developing all the leading makes of plates, and have taken excellent portraits in the garden," will not avail much in a portrait studio, except as an apprentice, or, perhaps, as an improver. The principal qualifications are lighting, posing, and, above all, tact with sitters, things only gained by experience. Technical school certificates, as a matter of fact, are looked upon very lightly indeed by practical photographers when engaging assistants.

LUX.—1. A very considerable majority of the lantern lenses in use are defective in regard to flatness of field, but this we are happy to say is not the case with all of them. Several opticians have devoted special attention to this defect, with the result that excellent definition at the sides as well as in the centre can now be obtained. A good doublet or rectilinear constructed for camera use would certainly answer for projecting, but it would not transmit so much light as a properly constructed lantern objective. 2. Nine inches focus would be suitable for your purpose. 3. A camera lens would not be likely to suffer from the light or heat.

T. A. SHAW.—This correspondent says: "In burnishing my prints, one side always has a much higher polish than the other. This would seem to indicate that the pressure on one end of the bar is greater than on the other. But, as there is only one central screw to adjust the bar, what can be done?"—The only way we can see is to do away with the central adjustment, and have two others fitted near the ends of the burnishing bar. If the burnisher is a small one, perhaps the difficulty may be met by passing the print through the machine several times, reversing it each time so that both sides in turn get the greater pressure.

SICCATIF writes: "I am troubled very much with the damp attacking everything I have in the studio, in spite of the heating stove. I am aware that a wooden building is not equal to a stone-built one for resisting the action of the atmosphere. I don't want to use the waterproof felting, on account of the objectionable smell of tar it gives off; but is there not some other suitable non-conducting material or solution that could be applied in the inside of the building? I shall feel much obliged if you can help me in this matter."—The waterproof felting should be applied outside the building, it would answer its purpose better there, and then there would be no objectionable smell within. Or the outside can be covered with sheet zinc. Another way would be to line the studio with wood, allowing a few inches between the inner and outer walls, and filling the intervening space with sawdust. Of course, in this case, the outer walls must be rendered perfectly waterproof or the end sought will not be secured.

HACKNEY PHOTOGRAPHIC SOCIETY.—Arrangements for January, 1893:—All meetings at 206, Mare-street. 3, Smoking Concert. Members willing to add to harmony of evening, please communicate with J. Vining, 60, Kenninghall-road, N.E.; or, Hon. Secretary. Mr. Penny has kindly promised use of piano. 10, *Some Contributories to Artistic Effect*, by Mr. A. Horsley-Hinton. 17, *Lantern Slide Colouring*, by Mr. S. J. Beckett. 24, *A Day in the Zoo* (Lantern Night) by Mr. Lewis Medland. 31, *Transparencies by the Carbon Process*, by Mr. W. E. Debenham.

FORTHCOMING EXHIBITIONS.

1893.		
February 1	.....	*Cleveland Camera Club. Hon. Secretary, J. J. Hallam, 11, Amber-street, Saltburn-by-the-Sea.
,, 7, 8	.....	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.
,, 16–18	.....	*Woolwich Polytechnic Photographic Society. Hon. Secretary, W. Dawes, 145, Chesnut-road, Plumstead, S.E.
,, 18	.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb, 100 High Holborn, E.C.
March 1, 2	.....	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
April 17–29	.....	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

JOURNAL OF PHOTOGRAPHY.

No. 1704. Vol. XXXIX.—DECEMBER 30, 1892.

INDIA TINTING OF PHOTOGRAPHS.

It is astonishing to what extent the mind and judgment are influenced by simple physical agencies. We look at an outdoor scene through glasses of various colours; through red, and we instinctively feel the heat of Calcutta, with its copper sky; blues of certain phases of tint transport us to the Arctic regions or at the least to winter in our own land; green to moonlight, and so forth through the innumerable shades of colours now produced. Spring, summer, autumn, heat and cold are alike suggested by such agencies.

As in nature, so with the examination of photographs and paintings. The late Sam Bough could paint winter scenes so warmly, that while snow lay everywhere around one almost felt impelled, even in chilly December, to throw off one's coat and go outside to partake in such pastimes as were suggested by the composition.

Take up a photograph of almost any kind and observe the effect on the judgment of interposing glasses of various colours between it and the eye. Just such a similar effect is produced on the observer by staining the photograph itself, a fact of which albumenisers and other preparers of sensitive paper seem to be well aware, as witness the rose-tinted or pearl-tinted papers now in commerce.

We some years since indicated the means by which photographs may be immensely improved by having a suitable tone imparted to the paper after they are finished, so far as the mere photographic operations are concerned. If, previous to being dried after washing, the prints are immersed for a few minutes in water in which a few drops of any of the aniline dyes have been dissolved, Judson's dyes for instance, they will be found to have acquired an even and beautiful tint that will be more or less permanent, that is, if they be not such colours as will bleach under protracted exposure to sunshine. It was in this way that some sensational and greatly admired moonlight views of Venice, still to be seen in the shop windows of printsellers, were produced, the white moonbeams tipping the waves and forming the high lights on some of the buildings being bleached out by judicious touches of a pen dipped in a diluted acid, by which the colour of the aniline is discharged. Hydrochloric or other acids serve either to discharge the dyed colour altogether, as in the formation of a moon, or to lower the tone when by an error of judgment this has been too pronounced. The degree of dilution is the factor by which the reduction of the tint is determined.

We have not found any of the aniline dyes produce quite such a good India tint on a photograph as can be imparted by a simple aqueous infusion of coffee. This, as our lady readers are aware, forms the means by which *old* lace is created out of the newer productions of that material, and we are aware of one gentleman, Mr. Weir Brown, who has been employing it of late with much success.

In such trials as we have made in India tinting, we have tried both coffee and tea infusions with nearly equal success, the strength of these being about such as that adopted in certain dry-collodion processes of a past period. But the balance of advantage seems to lie in favour of the former both in tone and in principle. The tannin in tea is not perhaps great, still we know that it reacts upon certain silver salts. This will be realised when we state that we have repeatedly developed negatives by its agency, and hence an application of such a potent agent to a silver photograph would certainly be a risky proceeding. Coffee infusion, on the other hand, would possess no harmful action; we at any rate have not found it to do so.

CHANGING BOXES *VERSUS* DARK SLIDES.

Although the necessity for stopping outdoor work altogether during the winter months does not exist now as formerly in the old dry-collodion times, still the shortness of the days leaves at the disposal of most amateurs a good deal of leisure that during summer would be devoted to printing or other purposes. This period of enforced idleness can scarcely be used to better purpose than for reviewing the past and preparing for the coming season.

The prominent feature of the past two or three seasons has been the almost universal adoption of the hand camera, and, though the number of these instruments is still on the increase, there are not wanting signs of an inclination to return to the use of the stand, and to larger sizes; but, in reverting to the use of the older form of instrument, the recollection of some of the conveniences of the hand camera will remain, and it is probable that the style of the ordinary camera will ere long undergo considerable modification from the introduction of many of the ingenuities of the smaller instrument. In no direction is this more likely to occur than in the method of carrying, storing, and changing the plates or films.

The double dark slide has for very many years maintained the premier position as the means for the purpose, but there is little use in attempting to deny the inconvenience that arises from the bulky character of separate slides, or the care that is necessary to keep them in working order and to prevent their admitting light to the sensitive films. So delicate is their construction that each hinge and shutter is a source of constant anxiety, and, considering the knocking about that the average slides have to undergo, it speaks volumes for the skill of the manufacturer that their lives are not much shorter and the accidents much more numerous than they are. A set of double slides too, for a dozen plates, more-

over, costs, if of the best construction, a considerable sum, as much as, indeed, or more than, the camera.

The dark slide, either single or double, is, of course, an absolute necessity in some form or other, and, where only one or two plates have to be exposed, or where a dark room is available for changing, it is undoubtedly the best means. But for out-door purposes generally, and especially when travelling, the inconvenience of a large number of separate slides is felt, and we may go back to the very earliest days of photography upon glass before we find the first attempt, in the form of a "changing box," to dispense with them. Previous to the changing box, however, in the old wax-paper days, the sheets of sensitive paper were frequently carried in a single slide, pressed against a piece of plate glass, a changing arrangement, usually in the form of a bag, into which the slide and the operator's hands could be passed, enabling the front sheet to be removed to the back after each exposure.

This forms, perhaps, the *acme* of primitiveness in changing, and with more or less modification may form, as in fact it does, the principle upon which really useful methods may be based. In its earliest application to glass plates, a single dark slide and an ordinary light plate box were employed in conjunction with the changing bag; and, as we look back many years to the use of such an arrangement, we are not cognisant of any feeling of inconvenience in its application.

The first changing box proper, that is to say, one which enabled the changing to be done without the aid of the bag, consisted of a grooved plate box with a hinged flap lid sliding in guides. In the hinged portion, which folded flat against the side of the box when not in use, was a slot provided with projecting jaws, into which the dark slide could be fixed, the end of the slide so attached being also provided with a corresponding slot, which was closed by a sliding strip of hard wood or brass. In use the slide was connected with the jaws of the changing box, and the folding lid was then slid into position over any particular groove, a simple metal catch falling into notches retaining it in place, so that the two slots accurately coincided, and allowed the plates to be passed into or out of the box as desired.

This, when well made, proved a useful and efficient contrivance, but its simplicity placed it within the capacity of inferior workmen, with the result that it was too frequently found unsatisfactory, besides which the loose flap was a nuisance, and unless great care was observed the lid was liable to slide off altogether at unexpected times. The first improvement was made by Ottewill, who replaced the flap lid by a double one, sliding in two parallel grooves one beneath the other. The upper half of the lid carried the jaws, which were closed when not in use by the under lid, which was kept in position by a spring catch. When the latter was loosened, and the under lid drawn out to its fullest extent, the slot of the jaws was found to be open and in position for the first plate, the two portions of the lid being then firmly clamped in their new position, and capable of sliding together so as to bring the jaws over each groove in succession. An index and pointer at the side of the lid indicated the number of the plate with which the slide was in connexion, and a lever catch, worked by the thumb of the operator, ensured its stopping in exactly the right place. In many of Ottewill's changing slides the inconvenient sliding strip by which the slot was opened and closed was replaced by one which folded back into a recess in the woodwork of the slide upon turning a button or lever fixed outside.

The next great improvement was the automatic changing box of American origin, first introduced into this country about 1874 by Hare. In all previous changing boxes it had been necessary to close the lid of the box before detaching the dark slide, and this of course involved the necessity of going through the sliding operation twice for each plate, with the consequent chance of forgetting the number of the plate last exposed. In the automatic changing box, by an ingenious arrangement, the act of sliding the plateholder or "back" into the jaws causes the slot in the lid to open, the slide itself then preventing the access of light; similarly, when the slide is detached, the first movement causes the sliding plate to close the slot before the slide itself has commenced to uncover the outer opening, and so the working of the instrument, so far at least as the opening and closing are concerned, becomes automatic. The slide itself is opened and closed by means of a spring catch operating upon the back which is hinged, and on being released springs back a little from the plate, relieving the latter of pressure and opening the slot to allow it free passage.

The value of these improvements is found in the fact that, when a plate is withdrawn from the box, the sliding lid may be allowed to remain in position until the plate is returned, and thus no uncertainty need arise as to its going into the right groove. In fact, there is no necessity to close the box until the whole of its contents have been exposed, for from its construction it may be carried as easily, and with as little danger of accident, when fully open or when closed, this result being attained by utilising a flexible sliding lid working into the inside of the box instead of the hinged flap or double lids of previous changing boxes.

Such were up to comparatively recently the only principal methods of carrying plates for exposure in the field. The introduction of hand cameras has added a large number of more or less ingenious methods of storing and changing glass plates, while the advent of flexible films has still further augmented the list. Some at least of the newer systems could no doubt, with little modification, be adapted to other than hand-camera purposes if manufacturers and the more mechanically inclined among amateurs would lead the way. It is very certain that so far, at least, none of the existing methods of carrying and changing either plates or films has proved to possess such advantages as to place it clearly in front of the rest, and hence it is that we still have the choice of various specially designed storage reservoirs forming part of the camera, detached changing boxes and roll-holders, as well as the old favourite double slide.

The faults of the latter have been, as already stated, their bulk and costliness, in addition to the great care always requisite in order to avoid light leakage. As far as concerns the expense there is absolutely no remedy, since, owing to the extremely delicate workmanship, the cost of a slide of best quality to carry two plates is nearly as great as that of a changing box for six times the number; whereas, in the case of the latter, at a comparatively trifling addition to the original price, the box may be made to hold double or treble the number of plates or films. Of course, when glass is in question, the capacity of the changing box is in a measure limited by the weight of the contents, but with films this is not so, at least to the same extent; and a storage box for cut or rollable films may be easily made to carry fifty or sixty exposures without exceeding in bulk and weight the old changing box for a dozen plates and considerably under in those respects double slides.

The double slide too can, unfortunately, not be made much more compact or lighter than it has hitherto been, owing to the fact that the greater portion of its thickness, and consequently its bulk and weight, are devoted to the shutters, rather than to space occupied by the plates. If that space be reduced to the utmost limit or entirely ignored, it is scarcely possible to bring the thickness of the slide below half an inch, and then the cost, owing to the necessity for finer work, would in all probability be enhanced rather than lowered. The future outlook would therefore seem to be in the direction of changing boxes.

The objections formerly brought to bear against these were their liability to break down or "stick" at awkward times, and the great risk of accidents from forgetting the number of the plate in use, and the consequent running it into the wrong groove. We can only say, after an experience of thirty years with changing boxes of various kinds, that we have not had half a dozen accidents from the causes named, and, when they did occur they were directly due to carelessness. If the plates are of the proper size and thickness, as well as properly cut —and, what is of greater importance, if they are put through the changing operation before leaving home—all danger ceases from that direction, and if a memorandum be systematically made of each plate directly it is either removed from, or returned to, the box, not much of a loophole remains for forgetfulness.

But even the latter danger disappears entirely if the system of grooved boxes be dispensed with, as has been done successfully, and, in place of it, the plan adopted of a box with two openings, one for taking out the plate, the other for returning it after exposure. These two openings can be intelligibly marked, and, in addition, can be so arranged that it is only possible for the plate to pass *one way*; and, if in addition an arrangement be adopted for stopping the exit when the last plate has been exposed, it is difficult to see how any mistake can occur.

This is no fancy picture of an impossibility, but the actual principle of more than one changing box we have seen in use, some of which we may describe in detail on another occasion.

A SIMPLE METHOD OF PRODUCING ENAMELLED PRINTS.

Although there is, unquestionably, a growing taste amongst the public, the same as there is with the more artistic photographers, for matt and rough-surface-paper pictures, still there is a great demand for those with a highly glazed surface, and that too notwithstanding that they have so frequently, of late years, been decried as garish and only fit to adorn sweetmeat boxes and the like. This fact is evidenced by the large number of prints mounted in optical contact with glass "opalines" that are produced and which command such a ready sale, as well as the constant demand for enamelled portraits; also by the additional fact, that with the gelatino-chloride printing-out paper it is very general to squeegee the face of the print in contact with a glass or other polished surface, in order to still further enhance the gloss on the pictures.

Seeing that enamelled pictures are still being largely called for, and, judging by the present taste of no inconsiderable section of the public, are likely to be for some time to come, it is well to consider whether the present method of producing them is the best, namely, that by enamelling a silver print with gelatine and collodion? We think it may be conceded that it is not. The operations are troublesome, and occupy considerable time from the beginning to the finish, while, after all, but a more or less fugitive result is obtained. It has often been a surprise to us that a much less troublesome, and more expeditious, method of producing enamelled pictures has so long been neglected, particularly when it is considered that the results obtained are unquestionably permanent—a condition that cannot be claimed for any other process by which enamelled prints are made. We allude, of course, to the carbon process.

This process, now that ready-sensitised tissue is a regular article of commerce, is the simplest and at the same time the most expeditious system of making highly enamelled pictures. All that has to be done is to develop the exposed tissue on a collodionised glass plate, squeegee on the transfer paper, and allow to dry. When it is stripped off, there is the finished print, with all the highly glazed surface of a silver print enamelled with a film of collodion and gelatine in the usual way. Toning and long washing are dispensed with, and the pictures can be obtained in a great variety of colours, according to the tissue employed. Furthermore, by the system of developing on the yielding, yet, as it were, cementing film of collodion, the softer and more delicate half-tints are secured in greater perfection than in, perhaps, any other form of carbon work. Indeed, this particular system of working may be considered as a refinement of carbon printing.

As the carbon process is now so generally understood, it would be superfluous to say much on the subject; still, it may be well to give one or two practical hints on that phase of it now under consideration, because the plan of developing on a collodion film, to secure the highly enamelled surface, has not received a very large share of attention during the past few years. A glass plate is thoroughly cleaned, and then treated with French chalk in the customary manner. It is then coated with enamel collodion, such as that employed for silver prints. After the collodion is well set, the plate is immersed in cold water until the solvents are washed away. When the greasiness has disappeared, the film is ready to receive the exposed print, or prints—for each plate may be large enough to hold several. This is desirable when working on a commercial scale, as it takes no longer to develop half a dozen impressions than it does one. The exposed prints are soaked in water in the usual way, and then laid in position, face downward, on the wet collodion film. A piece of indiarubber cloth is then placed over the whole, and the squeegee applied, as in other methods of working. The plate is then placed between blotting-paper for a short time. The pictures are next developed with warm water and alumed. Indeed, these operations differ in no wise from the ordinary routine now so well known to every novice in carbon printing.

When using ordinary glass as a temporary support, a little difficulty may be experienced at first in judging of the development, as the picture, at this stage, is viewed by transmitted whereas, when finished, it will be seen by reflected, light. But with very little experience this difficulty will disappear. However, the effect in the finished result can always be judged with certainty by putting a piece of white paper behind the glass and looking at the image by reflected light. In place of plain glass, polished opal may be employed. This does away with the difficulty just alluded to; but the glass is more expensive, and possesses no advantage, after a little experience has been gained with the other. When the pictures have been alumed and rinsed, the plate may be allowed to dry, or the

transfer paper may be attached at once. When the latter is done, too much pressure should not be applied with the squeegee, as it might "squash" the image, which is still tender. If the prints require any spotting, they must be allowed to dry. The spotting is then done on the carbon film, with tube oil colours, thinned with rectified turpentine, which will dry in a very short time.

As soon as the transfer paper is attached the pictures become analogous to ordinary silver prints, after they are squeegeed on to the gelatined collodion, as regards the mounting and finishing, and this may be conducted in precisely the same manner to secure the highest gloss. With regard to the mounting, some prefer, after the back of the transfer paper has become surface-dry, to apply a second or even a third sheet of it. Then, when the pictures are stripped off, they may be trimmed and attached direct to the mounts, with glue applied at the edges, without fear of disturbing the brilliancy of the surface. If the prints show any tendency to leave the glass before they are perfectly dry, it is a good plan to put a few letter-clips round the edges of the plates to secure them. The best kind to use are those known as "bull-dog" clips, which may now be had with jaws six inches long. One of these on each edge will be sufficient even with large plates.

Non-photographic Latent Images.—It is now a long time since the question as to the "mechanical or chemical" nature of the latent image was considered worthy of discussion, though the older of our readers will remember many severe discussions on the subject; but at the Physical Society a little time ago another old, much-argued topic was revived in the shape of an account of a series of original investigations on "Breath Figures"—*i.e.*, visible images produced on glass when it was breathed upon after certain previous treatment. The paper was by Mr. W. B. Croft, and described his success in repeating results described by Professor Karsten, of Berlin, fifty years ago. The effects Mr. Croft obtained were as singular as interesting. Briefly stated, they consisted in placing a coin or coins on sheets of scrupulously cleaned glass, passing a powerful electric current through glass and coin, the whole previously covered with tin-foil, and observing how the glass acted when breathed upon. No change was visible under the microscope, but when either side is breathed upon a clear frosted picture of that side of the coin that faced it is seen upon the surface of the glass. Without any electricity, similar "breath figures" were produced when "stars and crosses of paper are placed for a few hours beneath a plate of glass." Writing on paper, done some hours before the experiment, will similarly reproduce itself, as also if an ivory style is passed with slight pressure. Later on in his paper he alludes to the well-known case, a glass, which has for some years lain over a framed picture, carefully protected from the entry of dust, showing a distinct representation of the picture below it. "Possibly," Mr. Croft says, "light and heat have loosened dust particles, and these have been drawn up to the glass by the electricity made in rubbing the outer side to clean it." These are a few of the leading points of the paper, the whole of which may be seen in *Nature*, December 22. But we would desire to point out what, as evidenced by the scant bibliography appended to the article, that after Moser (referred to therein) had published his investigations (they appeared in the *Journal of the Academy of Sciences of Paris* for July 18, 1842), wherein similar effects were described *in extenso*, and the claim advanced that they were due to the action of latent light stored in the impressing object, Mr. Robert Hunt took the subject up, and experimented largely. The effect of this experiment was to convince himself that Moser's theory was an erroneous one, for he obtained analogous effects when he used electricity in a manner very similar to Mr. Croft. But he did not content himself with breath figures; he deposited mercury on metallic plates, and so secured an absolutely permanent image. The multitude of experiments that this indefatigable experimenter made on this one subject alone are fraught with interest, and it is merely enough now to refer to them. They will be found described in the chapter on "Thermography," in the treatise on *Light*, by Robert Hunt, reprinted from the *Encyclopædia Metropolitana* (1853).

Arborescent Photographs.—Some of the most beautiful effects to be found in nature's handiwork are those so plentiful this present season, the arborescent forms of frozen moisture on window panes. Some exquisite photographs have been taken of them and utilised in various ways. On one occasion a Christmas card was made up by one of our readers with such a picture as a basis; on another a pattern designer was able to ornament a damask tablecloth by adopting its forms and so on. Lately, however, interest has been formed in yet another manifestation of the freezing of water. The pages of our contemporary, *Nature*, contain a number of letters showing how interesting and beautiful are the forms produced by frozen wind, whether the thick slush of the roadside puddle or the pinguid ooze that distinguishes the footpaths in a wet, dirty season. The photographer in search of novel effects may evidently with advantage find here fresh field for enterprise.

A New Mode of Silver Plating.—A new method of electro-depositing a silver alloy has been patented, and experimental plant to prove its value has been in action for some considerable time, and so favourable are the results considered that a Company is now being floated to work it. To photographers it possesses a double interest. It utilises the well-known metal cadmium, and it promises to supply a coating cheaper, harder, more durable, and less liable to tarnish than the usual electro-silver coating. We need only allude to the rollers and plates of photographic rolling presses to point out the value of such a method if all that is promised for it be fulfilled. Many photographers start using such presses, but we should like to know how many of them find it convenient to have the rollers and plates recoated when they are found in course of time to be worn away? The ordinary electrically deposited silver is so soft that a very little friction suffices to abrade and wear away a considerable thickness. A coating thick, strong, and little tarnishable will be a boon, and we should predict a great success for the "Arcas Plating Company."

Gum Arabic.—Mr. W. F. Howlett writes to *Nature* from Pahiatua, New Zealand: "Can you inform me what is now sold in England as gum arabic? I used to be able to buy a soluble gum: what I get now is the same in appearance, but it will not dissolve. It swells up, truly, but will not form a homogeneous filterable solution. It would be a great boon to small buyers if such things were sold under their proper names. Am I right in supposing that since the Soudan trouble gum arabic has disappeared from commerce?"

Captain Abney in America.—We understand that Captain W. de W. Abney, F.R.S., has been invited to represent the Royal Society on the occasion of the 150th anniversary of the American Philosophical Society in May 1893.

The Darkening of Silver Chloride.—In the December number of the *American Journal of Science* Mr. Carey Lea, in the course of some notes on silver chlorides states that fused silver chloride, poured into petroleum and placed in the sunlight without removing it from the liquid, is instantly darkened. From this it appears that the presence of oxygen or moisture is not essential to the darkening of silver chloride in light. The chlorine may be taken up by some other substance.

THE PHOTOGRAPHIC MIRAGE.

Mons. Gaston Tissandier treats, in a recent number of the *Paris Photographe*, of this singular photographic phenomenon, which he has studied for several years. The instances he gives of its occurrence are extremely curious, the first being supplied by M. Paul Roy, professor at the Lycée in Algiers. M. Roy stated that at an elevation of 250

metres, where there was a slight mist due to the heat of the sun (the time being 8 A.M.), he took a portrait of his son with the full aperture of the lens, giving a second's exposure. With a clear atmosphere, M. Roy said that this would have been far too much exposure, one-twentieth of a second sufficing. The lad was seated quite clear of any shadows, with uninterrupted light full upon him, the background being formed of dense trees and bushes. A slight current of air showed, by looking at the background of trees, that the mist was in motion. When M. Roy developed the plate he was extremely surprised to see his own portrait, in the attitude in which he was when making the exposure, behind the picture of his son, and having a somewhat silhouette-like appearance. Our esteemed contemporary reproduces the photograph. M. Roy further observes that the image of himself was not well defined, as of course he was not motionless at the time of the exposure, and he also states that he made other attempts to repeat the experiment, but without success.

In the foregoing case, the image of the operator, as M. Tissandier observes, is clearly visible. That gentleman compares the picture to a "spirit photograph," of the kind obtained by double exposure. Here, however, there is no suspicion of cheating, and hence he concludes that the image of the operator was reflected on to the thin curtain of mist behind the sitter. He also takes occasion to remark that it is well known that shadows are occasionally cast on fog, and surmises that, in this case, the shadow of M. Roy, though truly cast on the mist, was not visible to the naked eye, although sufficiently sensible as to impress a plate by the aid of a lens.

In a second case, M. Tissandier alludes to a photograph, taken by Mons. C. Le Corbeiller, of the statue of David, on the Place Michael-Angelo, at Florence, with the image of the statue and its pedestal showing in the clouds. The photograph was taken one afternoon at the end of April, after a violent rain-storm; the sky was cloudy, the picture had three seconds' exposure, and M. Le Corbeiller states that, at the moment of exposing, the cloud image was invisible to him. M. Tissandier considers that there is a strong analogy between the explanation attaching both to the latter and the former cases of mirage photographs; but he withholds any definite opinion as to the actual cause of the phenomenon, wisely hinting that it is well to be guarded against mere illusions—and defects in one's apparatus.

After referring to the case of the transparent figure shown in a view of the Himalayas, to which our contemporary, the *Journal of the Photographic Society of India*, recently devoted a large illustration—a phenomenon which gave some of our Indian friends considerable trouble to account for—M. Tissandier concludes by regarding a photograph by Dr. Bernard as offering a phenomenon analogous to the foregoing. This picture (which is reproduced) is that of an hotel, the windows of which are reflected on the ground in front of it. The windows, however, are not "turned round" as regards top and bottom, as should be the case in a direct reflection.

A photograph of a clock, with its own reflection "in space," was also sent to M. Tissandier, who hesitates to say whether this and the foregoing phenomena are caused by double impressions, or by mirage. He, however, seems inclined to regard the photographic mirage as playing a part in the production of such double images as the first one here cited. The above facts are as interesting as they are curious, and might be worth studying.

PHOTOGRAPHING STAINED-GLASS WINDOWS.

II.

In a previous article on this subject I referred to the coating of the back of the plates with asphaltum as a preventive of halation, and mentioned that in my practice I found it more convenient to remove same *after* development rather than previous to the plate being developed, thus avoiding the chance of fingering and soiling the plate in the dark room.

This backing being on the glass side of the plate, and not being removed previous to development, of course prevents an operator from being able to judge of the density of his plate during development by looking through the film against the light, as in ordinary practice with unbacked plates; but this need not in any way deter a worker from adopting this mode of developing, for the image can be seen sufficiently well by looking down on the plate as the development proceeds, and any one after a little experience will have no difficulty in being able to judge of the progress the plate is making in the way of density by the manner in which the image comes along, and can soon tell whether the exposure has been about right.

A very important point, doubtless, is the getting of satisfactory gradations and suitable densities in the negatives. Over-density is as fatal to success as too little, for with the former much delicate detail is apt to be buried. An intelligent worker, however, will be able to guard against errors in this respect once he has had a little experience in the use of isochromatic plates. In my practice I find a developer weak in pyro gives most harmonious results. The following is a good formula:—

First and foremost, use plenty of developing solution. This should never be stinted, and for, say, a twelve by ten plate at least twelve ounces ought to be used in a dish but very little larger than will hold the plate. I mix—

Cold water	12 ounces.
Sulphite of soda	2 „
Dry pyro	20 grains.

This is flooded over the plate, and while on the negative I place in the developing cup half an ounce each of saturated solutions of carbonate of soda and potash. The pyro solution is then replaced in the cup, and the whole reapplied. The image generally comes along in beautiful gradations, and when the shadows begin to veil over development should be stopped, the rest of the operations being conducted just as in ordinary cases, a solution of bromide being at hand if development rushes up too soon.

After the plates are fixed and well washed, the asphaltum is easily removed by scraping off with a blunt-edged knife.

A very important item when developing or using isochromatic plates in any form is the guarding of the plate from ruby or other light during development. I firmly believe one-half of the failures in the working of these admirable plates is due to want of proper precautions in this respect. After a good many trials I am inclined to think that the safest light to use is two thicknesses of deep orange with an intermediate sheet of deep green glass, but even with this the film should be shielded by a cardboard over the developing dish during development, and the progress watched at intervals. To a worker accustomed to taking liberties with ordinary plates, doubtless this at first will prove irksome, but the extra precautions are more than repaid by the marvellous results obtained.

I have said that for exposure sunlight, in most cases, is the best to employ. Nevertheless, circumstances will transpire in which it will be found, owing to the situation of the window being placed with a northern aspect, that it is impossible to take advantage of sunlight for making the exposure. The work in such cases must then be done with the best diffused light obtainable. Another troublesome circumstance often met with it when working by diffused light is the unequal illumination of the window from its close proximity to some building which intercepts the sky line. The result of this is seen in the top portion of the window being very much better lighted than the bottom. When this trouble is met with, the image should be carefully noted on the ground glass of the camera, and a thread line run across about the focal length of the lens in front of the camera just at the height where excessive illumination from the top of the window begins to fall off. This thread is fastened to some convenient supports on either side of the camera, and serves as a guide to an operator for shielding off the light by wafting up and down a piece of dark cardboard at intervals. By this means a more equal illumination of the plate is obtained.

The unveiling of stained-glass windows is generally a most interesting ceremony, and one that is not always performed by means of daylight. In cases where it is desired to bring together large audiences, such as a congregation, to witness the unveiling of, say, a memorial window in some sacred edifice, it sometimes happens that the congregation can only be got together as a body after business hours, or at nightfall; hence a system of unveiling by means of artificial light has come to be adopted, and, so far as the illumination of a window, for all practical purposes of inspection, for the time being, is concerned, the idea is a good one and works very well. The plan is to erect a platform at a convenient distance, facing the window, outside the building, so that a pair of powerful mixing jets can throw a disc of limelight over the window, the interior being darkened. An enthusiastic amateur friend of mine on a recent occasion was quite exuberant over the idea of being able to attend with his camera in the front of a gallery on this occasion, imagining he would succeed. I told him it would be useless, and so the result proved.

Perhaps of all the various colours met with in stained-glass windows an operator will be most puzzled to account for the varying behaviour of his plates to the effect of ruby colours, even in one and

he same window. I once met with a case where for a long time I could not understand how I failed to get equal results from the ruby portions of a window, the colours of which, so far as the eye could judge, seemed to be identically the same. This was most noticeable in a case where the centre figure, with its surrounding, was extended over the mullions into other windows alongside. The ruby in the centre panel came out well represented on development, but the side panels showed a distinct baldness when compared with the centre. On inquiry at the glass-stainer's, and showing a proof print from the negative obtained, I was met with a laugh, and informed that there were several kinds of ruby glass, and that doubtless the shading-off so admirably represented on the window was obtained by using a special sample of ruby-coloured glass specially prepared to obtain gradations of tints whereby a fine plastic effect is obtained. I was soon deeply interested in these different samples of ruby-coloured glass, and in a few minutes had three distinct samples placed before me the colouring of which it was almost impossible to detect any difference in. A close inspection, however, divulged the fact that they were entirely different. No. 1 was flashed ruby on yellow; No. 2, ruby on blue; No. 3, ruby on white; and these samples were not evenly flashed, it being very desirous at times to get variations, such as high lights on a drapery, by means of these thin portions; and in many instances where these graduated portions could not be worked in or utilised the practice of etching was adopted. I soon found out how I had been puzzled over the samples of ruby.

Blues, again, sometimes give curious results. In cases where the colours verge into a peacock tint, a good impression will be obtained without the use of any yellow screen; but in cases where the blues are of an ultramarine tint a yellow screen will be required. Different workers have their own particular fancy for using these yellow screens, some preferring them behind and some between the combination of the lenses; but I like best to employ a perfectly flat sheet of glass, one surface of which is flashed canary colour, up against the sensitive plate. Allowance must be made for this in focussing, but in practice sharp results are obtained quite easily with them.

Yellow screens, however, in my opinion, should be used with caution, for they often do more harm than good where a variety of colours is being dealt with.

T. N. ARMSTRONG.

ON SILVER HEMISULPHATE.*

ALL the specimens of this new substance contain a little phosphoric acid which cannot be removed. Reckoned as phosphoric anhydride it amounts to a little over two per cent. Three determinations gave respectively, 2·30; 2·09; 2·18, mean 2·19.

It is apparently united with silver, and this silver phosphate is united so firmly with the double sulphate that it cannot be detached. If it were not so united it would be dissolved in the nitric acid with which the substance is three times treated if it were normal phosphate, and if it were hemiphosphate it would be converted (if in a free state) to normal phosphate and dissolved.

Another attempt to remove this phosphate was made by heating the substance with sulphuric acid to 100° C. for ten hours, followed by copious treatment with boiling distilled water to wash out the sulphate which it was hoped would be formed at the expense of the phosphate. It seems difficult to believe that a silver phosphate could resist this treatment, but a quantitative determination showed that the proportion of phosphoric anhydride is not even diminished by it.

Other modes of formation than those described here were experimented on with the view of obtaining the substance free from phosphate, but without good result.

It is possible that the silver phosphate may be combined in definite proportions, and the approach to uniformity of composition somewhat favours this idea. But such a view would require the assumption of a large, perhaps too large, a molecule.

Analyses.

A. Material prepared from silver carbonate and dried at 100° C.

	(1)	(2)	Mean.
Ag	76·13	76·75	76·44
O	3·29		3·29
P_2O_5	2·30	2·09	2·19
SO_3	16·19	16·47	16·33
Water	1·78		1·78
	99·69		100·03

B. Material prepared by various other methods considered less reliable.

Determinations.

Ag per cent.	P_2O_5	SO_3	O
78·59			3·93
78·45			3·69
77·16			3·61
75·43	2·18	15·61	3·29
75·46			3·25
75·35	1·77		
Mean 76·74			Mean 3·55

The determinations of phosphoric and of sulphuric anhydride are placed opposite the silver determinations to which they belong. The oxygen determinations are distinct.

The most reasonable interpretation of these results is that we have to do with a double sulphate of silver hemioxide and protoxide in which a portion of sulphuric acid is replaced by phosphoric. The proportion of phosphoric acid seems to be nearly constant, three concordant analyses having given 2·09, 2·30, and 2·18, with a mean of 2·19. These proportions may be expressed by the formula:—

$$7(Ag_4SO_3Ag_2SO_3H_2O) + Ag_6PO_4Ag_3PO_4.$$

The comparison of this formula with results obtained is as follows:—

	Calculated.	Found (Mean).
Ag	76·78	76·44
SO_3	15·67	16·33
P_2O_5	1·98	2·19
O	3·80	3·29
H_2O	1·76	1·78
	100·00	100·03

This large molecule results from the relatively small proportion of P_2O_5, and although the figures obtained for phosphoric anhydride are very concordant, it perhaps is better to consider the substance as a double sulphate in which part of the sulphuric acid is liable to be substituted by phosphoric. If the silver phosphate is taken as adventitious, the formula becomes simply $Ag_2SO_4Ag_2SO_4H_2O$.

Decompositions.—The action of alkaline hydroxides is confirmatory of the above conclusions, and also offers further proof of the great stability of the substance.

When the double salt is placed in contact with excess of dilute sodium hydroxide it blackens, being converted into a mixture of the hemioxide which is intensely black, and the normal oxide. This decomposition, however, takes place much more slowly than with the salts of the protoxide, so that (unless heat has been applied), if after ten or fifteen minutes the alkali is poured off and the oxides are dissolved with dilute nitric or sulphuric acid, a considerable residue is found of the red-brown double salt which had escaped decomposition.

With continued treatment with sodium hydroxide (that obtained from metallic sodium was used as being absolutely free from chlorine), the decomposition is complete.

The oxide thus precipitated was thoroughly dried at 160°—170° C., weighed and ignited. Five determinations of oxygen from various specimens gave 4·73; 4·63, and again 4·24; 4·19; 4·17 per cent. of oxygen respectively. A salt with the constitution already described should yield one molecule each of hemioxide and of normal oxide, and this mixed oxide should contain 4·68 per cent. of oxygen. We have then:—

	Mean of 5 Determinations.	Calculated.
Oxygen per cent.	4·39	4·68

The double salt is more readily decomposed by hydrochloric and hydrobromic acid, or even by alkaline chlorides or bromides. Under their action it instantly blackens. That part of the silver that exists in the form of hemisulphate is converted into black hemichloride or hemibromide. The extreme instability of these hemihaloids causes them spontaneously to resolve themselves into metal and normal haloid. They rarely remain as hemihaloid for more than an hour or two, and often for much less time. The change is often quite sudden, and is easily observed by the alteration of colour, the black of the hemihaloid passing into the metallic gray colour belonging to a mixture of normal haloid with metallic silver. The hemibromide seems to be little less unstable than the hemichloride.

This instability does not render an analysis impossible, since both the products of the change are insoluble; but renders it somewhat more difficult, as the freshly-formed silver haloid tends to run through a filter. Sometimes, indeed, it seems as if traces of the silver chloride

* Concluded from page 823.

were for a few moments soluble in water with a yellow colouration. The appearance of this yellow colour in the water is apt to be the first indication of the splitting up of the hemichloride.

Two analyses were made, one of material obtained by acting on the brown salt with dilute hydrochloric acid; this contained 81·79 per cent. of the silver. One by decomposing it with sodium chloride; this gives 81·93 per cent. A substance having the formula already given should, by conversion into chloride, give a mixture in which two-thirds of the silver should exist as hemichloride, and one-third as normal chloride. We have then

	Found 1	Found 2	Mean.	Calculated.
Ag per cent. -	81·79	81·93	81·86	82·35

a result sufficient close to afford a confirmation of the constitution assigned.

When the brown salt is decomposed with dilute hydrobromic acid or an alkaline bromide, a corresponding result is obtained. By treatment with hydrobromic acid a mixed bromide resulted, which proved to contain 66·06 per cent. of silver.

A general consideration of all the reactions which I have obtained seems to indicate that the action of sulphuric acid and sodium hypophosphite on silver carbonate does not lead directly to the production of the double salt which I have described, but that the hemisalt is produced in excess, often in large excess; that the nitric acid oxidises this excess, being able to attack the *free* hemisalt, but not that portion which is combined with protosalt and so rendered stable. It follows that, whatever has been the original relative proportion between the two salts, the nitric treatment leaves always one molecule of each. If it were possible to control the formation, it is not improbable that a pure hemisulphate might be obtained. But the action of the hypophosphite tends so strongly to carry the reaction still further, that reduced silver appears, and in removing this with nitric acid the double salt results. A confirmation of this is found in the fact that the treatment with nitric acid much reduces the deep terra-cotta colour of the original product. If this difficulty can be overcome, we may yet obtain hemisalt isolated.

There is reason to suppose that numerous other compounds of silver hemioxide with oxyacids may exist. These compounds cannot be obtained by acting on the normal salts with sodium hypophosphite or with hypophosphorous acid, but it appears probable that they may be produced when the normal salts are formed in the presence of sodium hypophosphite. If to the last-named salt we add a solution of a salt capable of precipitating silver nitrate, and then further add silver nitrate, we obtain precipitates which, after standing some hours with frequent stirring, appear to contain compounds of silver hemioxide. But these products do not resist the action of nitric acid; consequently there appears to be no means of purifying them and of deciding with certainty as to their nature.

When sodium citrate and hypophosphite are dissolved together, and a little silver nitrate added to get rid of chlorides, then after standing and filtering more silver nitrate is added, a precipitate is obtained which, after a time, appears to contain silver hemicitrate in an impure form. When a little of this precipitate is put into much water containing a trace of ammonia (five or six drops to 100 c.c.), a fine rose-red solution results.

Most oxysalts of silver are darkened by light. In a paper published in this *Journal* for July, 1887, I mentioned that films of these salts exposed to light and then treated with dilute hydrochloric or hydrobromic acid appeared to be converted into hemichloride or hemibromide, and argued therefrom oxyacid hemisalts of silver must exist, and be formed by action of light on normal salts. I believe that I have been able to prove the existence of a hemisulphate with a strong probability that many other hemisalts may be formed both by the action of light and also by purely chemical means. It is possible that at some future time we may succeed in obtaining some of these compounds in a state of purity.

M. Carey Lea.

EXHIBITIONS AND JUDGES.

I have mentioned the Photographic Society of Great Britain as unquestionably the best Society to take up a question of this importance. Now, presuming that to the Photographic Society of Great Britain are already affiliated the following societies—Carlisle, Newcastle, Sunderland and Darlington, Liverpool and Manchester, Birmingham, Nottingham, Leicester, Derby, Northampton, Gloucester, Bristol and Cardiff, Ipswich, Norwich and Yarmouth, and Tunbridge Wells—we have the nucleus of a national photographic union. Each of these societies should hold an exhibition yearly, *private* or open. The open exhibitions might be arranged somewhat as follows:—

1893. London, Manchester, Newcastle, Norwich, Notts, Derby, Bristol, Northampton.

1894. London, Liverpool, Birmingham, Carlisle, Sunderland, Gloucester, Ipswich.

1895. London, Manchester, Newcastle, Yarmouth, Cardiff, Leicester, Darlington, and Tunbridge Wells.

1896. London, Liverpool and Birmingham, Norwich, Notts, Derby, Bristol, and Northampton.

This gives us an open exhibition every year in London, every *two* years at Manchester, Liverpool, Newcastle, and Birmingham; every three years at the remainder. The *dates* of these open shows to be fixed by the secretaries after consultation, but in such a manner as to avoid a plethora of exhibitions at one and the same time. Private shows to be in the hands of the individual societies, but open exhibitions to be under combined management. The profits, if any, to go to a central fund; any losses—and these should be anticipated—to be made good from the same source.

Medals of various values might be given in this way. A new picture may be shown, but no matter what its excellence it receives a first-grade medal; this enables it to compete at next showing with others of like standing it possibly here receives a second-grade medal, which entitles it to compete for a third-grade award, by which time the competition would be one of giants, and a fourth-grade National Union medal and diploma, difficult of achievement to the insatiable competitor, might be added a championship prize for the best picture of the year. The pictures of the fourth grade, or sufficiently good duplicates, to become the property of the National Photographic Union, and would go to make one of a series which would form the backbone (not for competition) of any local exhibition, where not previously exhibited, finally reaching its well-earned repose on the walls or in the portfolios at headquarters.

At first sight this might appear hard on the eminent photographer, that, in fact, just as in Association football certain leading clubs are exempt from the qualifying stages for the Association Cup, these eminent men should be allowed some licence. Be this how it may, we know for certain that some of these eminent men are very uneven workers and are not above showing pictures far below their capabilities.

With regard also to the question of one man sweeping the board, the rule should be that one medal only be given for one picture, but a certificate of entry to a higher class might be given for others shown. Then how should we deal with the "one-picture man?" Simply in the highest grades confining them to men who have achieved a certain number of successes.

Who is to do all this judging? This is a difficult problem indeed at first sight; but, when we look into it, it is clear that in the earliest stages the operation would be merely a "weeding out" of certain work, and that the competition proper would not begin until the higher stages were reached. Marks would have to be given each picture, and the process would necessitate some time and much pains. It is possible, of course, to do the judging economically, and in most exhibitions it might be advisable for a small local committee to undertake the work, but undoubtedly *one* Judge sent down from the headquarters to adjudicate and report would be likely to give most satisfaction. He would be able to report on the work individually and collectively.

With regard to such Judges, it may be asked, where are they to be found? But surely this can be answered. There are highly intelligent and well-informed members of the profession, successful in business, of high standing, liberal, sympathetic views, and able to express their opinions. Some are still in business, but probably are not so tied to the studio but they would be able and willing to adjudicate. A few, perhaps, have retired from active work, but with their interest in the welfare of photography unabated. These doubtless would be willing to take a journey north, south, east, or west. The work should not be done for nothing, and a fee (as liberal as possible) should be fixed and paid by the central authorities.

All classes, except lantern slides, might be abolished. There is a great variety in photographs, from the merely topographical to the studies, more or less perfect, representing some idea or story. Now, unquestionably the *genre* must take the palm, and it is probable that, measured by grades, specimens of this class only would live through the grades requisite to achieve the highest point of excellence. It is clear that a pure landscape or bit of architecture would need to be transcendently beautiful to achieve the like distinction, and, even with regard to the figure studies, how many numerous degrees of excellence there are! Of the large number of admirable studies, how few linger in one's memory as do Robinson's *Carolling* and Sawyer's *Moonlight* and *Twilight* pictures! I mention these merely out of

considerations of space, not that I forget others; but it is easy to see that our best exponents of photographic possibilities would always be found on the top rung of the ladder.

I throw out these brief suggestions in the hope that others will take up the subject. By judicious kicking on the part of some of our forward men, we may land the ball safely into goal. J. Pike.

SPECTACLES AND MAGNIFIERS FOR PHOTOGRAPHERS.

The interesting editorial article on "Magnifiers for Retouchers," opens up a subject not only of practical importance, but also of great moment to photographers, as regards the preservation of eyesight. The power of vision varies so much, not only individually, but also in each eye, and if there is a distinct variation in focus, refraction, or muscular accommodation, then each eye should be separately suited. I have, in the course of a long period of sight-testing, found some curious differences in the two eyes. One eye, for instance, being long-sighted, the other, short: while on several occasions I have found that all the work is being done by one eye, and the patients were not aware of the fact until I proved it to them. The optometers, constructed on Dr. Smee's principle, are invaluable for sight-testing, because with it, not only can the focus of each eye be found, but the amount of accommodation registered. It also detects errors of refraction, such as astigmatism, hypermatropia, or over-sightedness, and also weak sights, which have little or no muscular accommodation. A normal eye, having a certain range of vision on the scale, it is easy, with a properly constructed instrument, to interpose lenses in front of the patient while looking through the standard eye lens of same, in order to lengthen or shorten the focus of the eye, the required amount to correct the short or long-sightedness as the case may be.

Even with this perfect arrangement something more is required in cases of astigmatism, and Dr. Tweedy invented a simple arrangement for detecting the presence of it, and by means of a frame of lenses, all rotating by the turning of a key or head attached to a pinion moving a rack running the whole length of the frame, finding the necessary correction. These lenses, rotating in the cells, are cylindrical in form, and have the property of elongating the object looked at through them, the degree of elongation depending on the radius of the cylinder.

A great number of persons are affected by astigmatism, and often without knowing it; and from the fact of never having known what it was to see *properly* they had no idea of their deficiency. Now, how can we find out if we have normal or perfect sight? First of all we must try *each eye separately* on small type and figures such as one gets in *Bradshaw* or the *A B C Railway Guide*, holding the book ten to fourteen inches from the eye; then, by looking at fine lines radiating from a central point, see if each line is divided from the next, and looks equally black and sharp. The best distance to be noted for both eyes, and also the range of distinct vision, from the nearest to the farthest.

If a magnifying lens is at hand, use that on the fine lines, and, should astigmatism be present to an appreciable extent, it will be found that there will be a different focus required for vertical lines to that which is required for horizontal.

In my own case, I see horizontal lines, and those near the horizontal, sharply much nearer than I see the vertical and those near to it. In fact, with a lens six or seven inches in focus, on looking at a number of parallel lines, drawn about one-sixteenth of an inch apart, I see them sharply (when holding the magnifier at the same distance from the eye) at a difference of about three-eighths of an inch, the distance from paper to lens being three inches in one case (horizontal) and three and three-eighths in the other (vertical).

Nearly everybody has a master eye—that is, are either right-eyed or left-eyed. By this is meant that one eye is the active agent in defining and giving the best impression of sight, while the other acts by sympathy. If, for instance, I concentrate my two eyes on a definite object, with something intervening in the true line of sight of same, I shall find that, on closing the master eye, the object has moved considerably; but, if the passive eye is closed, the object remains in the same position in relation to the intervening object—say one's finger against a gaslight at a far distance. Now, with regard to near objects when using a magnifier. If one has so trained the eye most employed to ignore the impression from the other, they can naturally see the object magnified without distress, and keep the second eye open. This is constantly done by microscopists and astronomers when using the microscope or telescope, because it is easier to the sight to work in this way. There is, however, a limit beyond which one cannot do this in comfort, and it is particularly apparent when using magnifiers over two and a half inches diameter, although I find I can, with an effort, use one of three inches. If one makes an ink dot on the lens when in focus with print at a part near the centre, when a certain letter is covered with one eye open, it will be found a second ink mark will have to be made nearly an inch away in order to cover the same object. This represents the difference (or the angle) of convergence of the two eyes. If a lens of four inches diameter or over is employed, then, the focus being longer, the angle is more acute, and the eyes can properly converge to the object when looking through the lens.

I was interested to try the effect of two double convex lenses of eight inches focus used as a pair of spectacles, instead of the magnifier, as suggested by the editor, and in a frame where the centres could be altered at will. I found with the optical axis the same as one's eye-width that the confusion was considerable when in focus, and, in fact, the separation of the two impressions of the object considerable. Even at the narrowest it could not be made to give a single image in my own case without considerable muscular effort, so I can quite think that any one peculiar or weak-sighted, with little muscular accommodation or natural adjustment of the eyes, could not manage with deep lenses. I found after getting a focus and seeing the object sharply, the image of it, seen by one eye, would slowly travel along, and be separated from half to one inch from the other image. Magnifiers are very often made of too short a focus for the diameter, and consequently have considerable distortion. It is far better to use a lens of moderate power that does not disturb the true form than see the object large and indistinct or distorted. Try the lens on straight lines, or on a square that is just included in the field of the magnifier, and if the former are curved or the latter not rectangular, do not use it, but have a compound lens made of *two* lenses to give the focus required. There is no doubt that in many simple of every-day matters of optics a great deal of carelessness is at time shown, and consequently that precious organ of sight, "the eye," seriously affected. G. R. Baker.

THE JUDGES AT WORK.

Whenever a gathering of *cognoscenti* is commenced for the purpose of apportioning praise, two initial stumbling-blocks present themselves. In the first place, all the members are not sufficiently known to each other to act in concert with such instant and reasonably perfect precision as they should; and, secondly, it generally happens that none of them are very clear as to the exact conditions under which they are to distribute their awards.

I particularly want these two points fully recognised, because they lend additional support to those modifications in the regulations of judging hitherto followed at the Pall Mall Exhibition below suggested.

Before coming to this, I would say that the Judges, having been in good time appointed, should each be furnished with a printed schedule, clearly setting forth that which each one is called upon to criticise, and should also receive a suitably drawn-up form on which he can register his opinions.

And now we arrive at the chief alteration which seems to be called for, *i.e.*, that in the future the judging shall cease to be *consultive*, but shall instead be strictly *individual* and *isolated*.

The advantages of this change are manifold. To begin with, its adoption ensures there will no longer be any chance that medals are bestowed by means of a kind of "give-and-take" procedure, which, amiable enough in its intention, encourages the glorification of the personal preferences of individuals rather than giving due weight to the aggregate opinion of the whole Committee; nor would there continue to be any risk of the Judges indulging in the undignified but very human practice of "follow my leader."

In most assemblies, and particularly restricted ones, there is to be found one man palpably taller than the rest—one whose *obiter dictum* has almost the force of law, and is in itself powerful enough to prevent the formation of any independent judgment.

Even when no such master-mind is present his place is usually usurped by the man of self-assertion, who, probably, comparatively deficient in critical ability, nevertheless imposes his views upon his reluctant but pliable fellows. Besides the inherent objectionability of this, it is distinctly to be deprecated, because the Society does not intend that such a practice should obtain. If the Society is well satisfied that the judgment of one man shall prevail, let it nominate the Judge, and legalise the judgment; but, if it be of opinion that it is not well for the great and extending diversities of expression in photographic art to be at the mercy of one person, however distinguished, then must the consultive form of judging be for ever swept away.

Whatever the size or material of the chess-board, the pawns thereon move just the same, and each one of us may readily from his

own maybe humble and limited experiences in consultive judging opine what is likely to happen in even the most "high and mighty" gallery where this system prevails; and, although the nett result may not always be the indiscriminate launching of medals, we know from recent occurrences that even the opposite extreme can be considerably hurtful to the cause of photography, especially when the ruthless withholding of rewards breaks an implied promise or a prescriptive expectation.

In order that isolated judging may be feasible, it becomes necessary to employ what is known as the *mark system*.

Without stopping to elaborate a description of this, let me shortly indicate by an example how it might be used.

There are, say, two (or some larger number) of Judges, A and B, for "landscape photography," each of whom separately inspects all the pictures. A awards to each exhibit according to merit, marks up to ten (or any other fixed maximum found most convenient) for *artistic quality*. B, for purely *technical quality*, awards a like number (or, if so arranged, a larger or smaller proportion of marks).

I am perfectly aware that there are some theoretical objections to the mark system, and also a few puerile practical ones, but they are none of them insuperable if the code adopted be carefully considered. Anyhow, if some small inconveniences, or some fanciful shortcomings, remain, such are far outweighed by the fact that the air is cleared from suspicion, or corruption, or undue friendliness. It would be worth far more serious sacrifices than are likely to ensue if the result be to place the judging for all time far above reproach.

Yet another good thing would follow the independent system, and that is the discouragement of works which are grossly defective in technique or absolutely "void and empty of every drachm" of art. That this is not uncalled for I can personally testify. In past years photographers of undoubted capacity and position have taken very serious umbrage because Judges, no doubt swayed by their inherent love of the beautiful, have given medals for prints which, although boasting of limner-like attributes, were painfully noticeable for faulty or negligent technique. On the other hand, quite a number of productions which show great perfection in the latter respect have, in spite of their utter disregard of the cardinal canons of art, been singled out for distinction, to the exceeding scandal of those who claim for photographic pictures a near kinship with painting.

One wholesome corollary of the adoption of the mark system is that doing so involves a more precise classification of exhibits than is now the case. Although classification is at present discouraged, yet, nevertheless, a rudimentary kind of grouping together of exhibits is made, if only in the minds' eye of the Judges; for it is in practice found to be impossible to compare productions which are largely dissimilar in *motif* and handling, except that they are photographs, there is but little in common between, say, Stevens's flower pictures, Birt Acre's *Story of a Cloud*, and Burchett's *Love Letter:* and so with portraits *genre*, cattle studies, sea pieces, lantern slides, and the rest.

It is, after all, but a small step, but none the less important, to do officially what is at present accomplished in an ill-regulated and informal fashion; even if the mark system be not adopted, the before-mentioned change would be well as leading to more ease in judging; by imposing upon the exhibitor the task of notifying upon what ground his exhibit seeks for distinction, the Judges are saved much irksome and uncalled-for drudgery. Yet another benefit which should follow the mark system is that medals would be competitive awards, and not, as now, given without limit, and sometimes without stint.

On the chief wall of the last Exhibition were no less than four separate series of landscapes, all truly charming and finished renderings of our island scenery; either set is doubtlessly worthy of receiving a medal in the absence of the other three. But why a medal each all round? One set must surely have been better than the others; in which case, why should the inferior be bracketed with the superior? It is not my duty to indicate which of the before-mentioned quartette deserved to be placed *primus inter pares:* but, whatever the cost, it should have certainly been incumbent upon the Judges to do so. Of course, under the present regulations, perhaps it was not merely politic, but also right and proper, for so much munificence in the distribution of rewards; but, although a more thrifty course of action would have resulted in much poignant disappointment, it would also have induced great future striving, and much instant appreciation in the value of the Pall Mall medal.

In conclusion, be it said that not the least merit of the system I advocate is that the personalities of those forming the jury of experts are merged into columns of figures; and thus it becomes all but impossible to blame one's friend—or, for the matter of that, one's enemy—should some one else's *chef-d'œuvre* come out first on the list of honour. Such, added to what I have written in the two previous articles of this series, embody the main remedial measures which, in my opinion, it were well that the executive of the Photographic Society of Great Britain should adopt in order to maintain, or rather increase, the prestige which should belong to the chief photographic "fountain of honour."

The suggestions made are, of course, but rough-and-ready jottings of a few reforms most urgently called for; and, if adopted, no doubt certain further complimentary alterations of a minor character will be needful. Thus the attainment of an absolute as well as a relative merit will have to be provided for before a picture or other exhibit shall receive a medal, and other subsidiary details considered which offer no insurmountable difficulty. On the contrary, if the members of the parent Society approve the principle of the scheme I have lightly outlined, they may rest assured that the subordinate machinery can easily be so fashioned as to work smoothly and efficiently.

HECTOR MACLEAN, F.G.S.

HOW A FAMOUS ANIMAL PHOTOGRAPHER WORKS.

MR. CHARLES REID'S NEW STUDIO AT WISHAW.

A CORRESPONDENT writes: A few days ago I had much pleasure in paying a visit to the gentle, genial Mr. Charles Reid at Wishaw. The man you all know—at least, by reputation and his work—for Reid's artistic studies of animal life are known and appreciated as far and wide as photography is known. In his own field he stands unequalled, and his productions are admired by all. For many years I have enjoyed the pleasure of Mr. Reid's friendship, and have often felt that his extreme modesty tends to do an injustice to himself; he seems to dread placing himself in a prominent position, so that only by his works do you know him.

During this visit he explained to me how he first started photography, and also how he began to take his first "artist's study pictures."

Away back in 1864, in a small village beyond Aberdeen, Mr. Reid kept a post-office, so you may safely say he was a man of letters. At this place a friend came to visit him, and with him he brought along a quarter-plate camera and lens. For three or four weeks Mr. Reid and his friend went in for the making of positive pictures, producing many failures, but some successes. Mr. Reid got quite enamoured of the work, and great was his surprise when his friend, who saw how much he was taken with it, proposed to leave him the apparatus, which he did; and from that time he has been a full-fledged photographer, so that he may be numbered amongst the early workers. From the north he came to Wishaw, eighteen years ago. He began to take "artist study" pictures as soon as he got settled in Wishaw. In relating to me his early experiences, he said:—

"Amongst the very first study pictures I made I took them down to Mr. George Mason, Glasgow, to ask his advice, and to see what he thought of them, and to see whether he thought a trade could be done in them if the idea was carried out. The enthusiastic manner in which these first productions were received, and the encouragement given me by Mr. Mason as to there being a big future in it, was one of the principal causes that led me to prosecute this branch of my business which has proved so successful, and I always think of that meeting with Mr. Mason with great pleasure."

The first lens he used in the animal picture work was a 2D Dallmeyer, but he soon renounced this portrait combination for a 3D Dallmeyer. Mr. Reid for his purpose found it rather slow, and now he uses a Dallmeyer rapid rectilinear whole-plate. Seven-by-five pictures were what he first produced, but now he takes them up to whole-plate.

He uses a Newman's shutter. When he got it first he found that the travelling plate, that rises and falls in the diaphragm slot, vibrated so much when working that it was useless for his purpose. He, to obviate this defect, had two rings fitted round the lens with adjusting screws, so that they could be bound tight. These are fitted close up to the moving plate, and from these rings he has little brass supports standing up, so that by this means he gets the plate to travel quite smoothly and free from vibration.

His exposures vary from a fourth of a second up to two seconds; but, after all his varied experiences, he says that he inclines to stop down, and give longer exposures whenever such a thing is possible. Out of many exposures on a subject, he is well content if he gets one or two successful ones. For development he uses pyro and ammonia. He has tried most of all the round of "best developers" that flood the market, but he returns to his old love with more satisfaction and pleasure than ever after such trials. He brought me a tray filled with medals, but, as he usually takes medals wherever he shows, it would be superfluous to enumerate them.

He showed me some examples of his later work, which were very

charming. One of these was a lioness on the back of a pony, taken in the open in Bostock's menagerie. In the middle of the operation Mr. Reid was rather startled by the sitter jumping down from the pony's back and trying to escape, but the brute was recaptured and made to sit again. He must have had a lively time of it when taking that picture, but he was at least rewarded by obtaining a good one. I saw a very attractive study, fully exposed and quite sharp, of *Mary had a Little Lamb*. The Mary was a baby, and the lamb's wool was white as snow. I saw horses and foals photographed to perfection; cows in fields, and cooling waters; poultry; birds of every feather, from the woolly chick to the graceful swan.

The new studio just built by Mr. Reid is a stone edifice of an attractive nature, forming the corner of two streets. It is two stories high. The studio is on the upper floor. Before starting to construct it, Mr. Reid had visited many of the best recognised places, and from each adopted those parts that suited his ideas, and the success of the finished result shows what might be attained by one who goes about with open eyes in search of the best points for his purpose.

The studio has a ridge roof, with a north light. The ridge is two feet off the centre, thus giving a greater slope on the north side, the slope coming down to within six feet of the floor, making an incline of twelve feet. The side of the studio from the floor to the lower edge of the roof is only six feet, with three feet of glass in the upper part, the lower portion being fitted with shelving for plants and flowers, with a graceful drapery underneath, behind which run the hot-water pipes for heating the place. The studio is forty-three feet long by sixteen feet wide.

The fittings and decorations are quite up to date. The curtains on roof for arranging the light are made of an art muslin festooned, and produce a very pleasing effect, being of a pale cream colour, with a faint Japanese pattern showing all through them. There is also a set of green blinds, fitted with spring rollers, for the purpose of giving increased variety of light effects. At the further end of the studio from that at which he takes his usual sitters are two real windows, and these Mr. Reid has utilised into a new style of background. The walls have been decorated so as to bring in the windows as part of the picture, thus forming an effect by which "at home" pictures can be produced with easy arrangement, and little trouble to the operator.

The studio is furnished with the newest appliances. Notable amongst these are the new American background stand, so favourably noticed at the last Convention, and Morgan's new patent shaded background.

The dark room is twelve feet square. The light is arranged by two frames, one of ruby and the other of yellow glass, with a sliding door over the top for daylight. The coloured glass is situated eighteen inches within the plane of the daylight pane, Mr. Reid finding this arrangement ever so much more safe to work by than when the coloured glass is placed close to the source of light.

The show-room is decorated with considerable taste, the fireplace being finished in encoastic tile, with an overmantel of artistic design, the windows being all filled in with stained glass, with plain places arranged here and there in the design for the fitting in of transparencies executed in carbon, and some in silver from Mr. Reid's own negatives. The hall door is also finished after this same design. The furnishing of the dressing-rooms is carefully studied for the comfort of clients.

As can be well understood, the negatives in such a business are kept with great care and perfect order, so that, when any special subject is wanted from amongst the thousands in stock, it can be had and handled at once. The printing is all done under glass. The house in which it is done is a lean-to, with sloping roof of hammered corrugated glass, which gives considerable diffusion of light.

Mr. Reid also does a considerable part of his own training. There is a department set aside for that branch.

The portrait business is large and important, and, with the assistance of his two sons, the management is efficiently undertaken. Lantern transparencies are also a growing business with him. Many examples of this class of work, of a very high grade, we saw when there.

He makes all his transparencies by the wet-collodion process, which he prefers. He has tried every brand of dry plates, but has failed to get results to please him, the collodion being the only process that gives results to meet his desires. He develops with iron, and tones with gold. The quantity of gold is not of so much consequence, for if excessive they tone at once, and when weak they just take the longer time.

Mr. Reid is called much from home. Agricultural and horse shows of every description, all over England and Scotland, request his presence with his camera; and, in spite of refusing many, his time is pretty well taken up with those that he accepts, and from such sources he brings home quite a wealth of pictures.

We often hear artists sneer at the productions of the photographer. They do allow that from a photograph they may get a suggestion or two to fill in some part of their compositions; but, as a whole, they are valueless, and never could take the place of studies from nature. In contradicting these assertions, Mr. Reid was saying that the quantity of oil paintings produced from his subjects was many, and, as can be believed, annoyed him very much. He was going down Leith Walk a short time ago, when he saw two oil paintings in an art-store window, line for line from his photographs; and that was just one of many such cases.

A large publisher asked the liberty to reproduce one of his pictures in a book that he was publishing. The liberty was granted willingly, but what was Mr. Reid's astonishment to find in the book when he saw it instead of one six pictures, copied with just the slightest alterations to make them different. So broadcast is this piracy, that he has serious thoughts of registering all his negatives as he produces them, to protect himself for the future.

PINHOLE PHOTOGRAPHY IN JAPAN.

[Photographic Society of Japan.]

ATTENTION has been called many times to the quality of photographs that can be obtained in a darkened chamber, or camera, without special optical apparatus—simply by means of a small hole in a very thin plate.

Amateur photographers can make pictures, pretty large in size, of landscapes, and even of monuments, without being obliged to buy lenses costing from $10 to $300.

No doubt, to reproduce plans and engravings, it is necessary to use the famous lenses of Ross, Dallmeyer, Beck, Hermagis, Francais, Nadar, and others. But we wish to perceive, when we examine a photograph, the particular effect which is produced on a more or less near-sighted eye by its entire surroundings, when it looks at nature from a little distance. It seems to us that, suppressing the lens, and replacing it by a pinhole, gives more artistic results as far as regards monuments, or landscapes without moving figures.

"Nevertheless, far from us," says an English journal, "is the idea of crying down the photographic lens which has, in the last year, attained so great perfection; for in the greater number of cases these instruments are, and will remain, indispensable;" but leaving out the instantaneous photograph, which has such charm for the amateur, and the portrait, the speciality of the professional, let us confine our ambition to obtaining, in as artistic a manner as possible, either landscapes or copies of monuments, and of these latter there are certainly no lack in Japan.

M. Meheux says that the most suitable hole is round, and drilled in a plate of copper or sheet brass of $\frac{1}{20}$ millimetre in thickness; it is necessary that the borders show no burr, and are bevelled, forming a cone.

Captain Colson has remarked that, although the depth of focus is unlimited, the greatest sharpness of definition for each size of hole is found at a determined distance, and he has succeeded in finding the proper focal distances for different diameters of holes. He has thus found that

The best definition for a hole $\frac{1}{20}$ millimetre is at	11	centimetres.			
" " " $\frac{1}{10}$ " "	20	"			
" " " $\frac{3}{10}$ " "	30	"			
" " " $\frac{4}{10}$ " "	44	"			

It may be mentioned that the size of the object to be reproduced is proportional to the distance from the apparatus, and to the distance from the hole to the sensitive surface.

It follows from this rule that, after having taken, for example, one view of an entire cathedral with a focal length of twenty centimetres, say, with the $\frac{4}{10}$ millimetre diameter of hole, if we wish to have the details of the gateway without moving from our place, it is sufficient to lengthen the focus to forty-four centimetres and to use the $\frac{6}{10}$ millimetre hole.

We may further remark that the Stenope—the name given to the above-mentioned plates—easily includes an angle of 100 degrees, or even more, without at all deforming architectural lines, and without destroying the perspective, which is far from being the case with even the most perfect wide-angle lens.

The length of exposure presents much less difficulty than with lenses; except we expose enormously beyond the proper time, it is nearly impossible to over-expose; we can always obtain a good negative by developing intelligently.

Nevertheless, if one must have a general approximate rule, we may say, as a general proposition, that the time of exposure is at least twenty-five times longer with the $\frac{3}{10}$ mm. hole than with a lens focussed upon the same view, and provided with a medium diaphragm; fifty times longer with the $\frac{4}{10}$ mm. hole; 100 times longer with the $\frac{5}{10}$ mm. hole; 200 times

longer with the $\frac{1}{16}$ mm. hole; it being well understood that we use the focal lengths corresponding to these holes.

But we can modify these times of exposure without over-exposing the plate. On the whole, this depends very much on the plates, the developer, and the actinic power of the light. Experience will be the best guide for every class of picture. Just the same as in nature, the sun has here great influence on the clearness of the view, more than it has when using lenses.

To sum up the advantages of using the Stenope:—

(1) More artistic definition than with a lens.
(2) Unlimited depth of focus.
(3) Perfect perspective for lines in architecture.
(4) Mathematical exactness in the scale of plans.
(5) The angle of view can include as much as 170 degrees.

J. Favre Brandt.

HINTS ON THE USE OF MAGNESIUM.

Before the South London Photographic Society on December 19 (the President, Mr. F. W. Edwards, in the chair), Mr. John Burgess, F.C.S., intimated that there were one or two points of difficulty with regard to his new process of colour printing which he desired to clear up before describing the process before the Society, and therefore postponed his paper on the subject, and substituted for it, "Hints on the Use of Magnesium." He said there was a great charm about the use of that substance, as it enabled persons to take portraits of their friends at home with their usual surroundings, and they were in no way dependent upon the weather in carrying out their intentions. He had for many years used magnesium largely for copying purposes, and his method of burning it was very simple. Sufficient magnesium ribbon was taken to produce the required amount of illumination and cut into lengths—the greater the number, the less time it took to burn. The lengths were fastened together at one end with cotton, and the whole inserted in a glass tube. On the outside of the tube a cork or piece of wood was fitted for convenience of holding the same. A spirit lamp was then placed on the top of the back of the camera, and after the persons to be photographed were arranged, and the adjustments of the camera carried out, the lamp lighted. The glass tube was then taken, and one end placed close to the lighted lamp, while the lengths of magnesium were pushed forward from the opposite end by means of a taper or something of that kind into the flame, causing the magnesium to ignite and burn as it was pushed forward.

The lecturer exposed two plates to illustrate his process, which were afterwards developed and handed round for the members' inspection. Various methods of using magnesium powder were described, and for illuminating a large space the lecturer considered that was more useful than the ribbon, provided the powder was mixed with chlorate of potash. Some persons objected to the use of the latter by reason of its explosive character, but if two parts of castor sugar was added to one part of chlorate of potash, and afterwards mixed with the amount of magnesium to produce the required amount of light, on burning it would be found to consume quietly, and had the merit of being non-explosive.

This mixture should be burned in a tin saucer or other similar utensil. A simple method of igniting the above mixture was to take a small quantity of sulphuric acid on a glass rod, and allow it to drop on the powder, which would cause it to burst into flame. Magnesium produced the most actinic light known.

Its intensity was increased by consuming in oxygen gas. The fumes arising from the combustion could be absorbed by passing them through a solution of hydrate of soda.

MULTIPLE COATED OR MULTIPLE FILM PLATES.

[Abstract of a Communication to the West Kent Amateur Photographic Society.]

The Theory of Halation.

As to the cause of halation, the first person to lay down any law on this subject was Captain Abney, and the theory first advanced by him has stood the test of time, and come to be universally accepted as the primary cause of what is known as halation. The theory is briefly this—that the rays of light from the brightly lit portion of the picture penetrate the film which supports the sensitive salt, and passing through the glass plate are reflected from its hinder surface back on to the film, and a moment's thought will show that the thicker the sheet of glass the greater will be the aberration of the reflected image from the original, and consequently the greater its interference with it. Though many attempts have been made to overcome or to minimise this reflection, such as grinding one or both surfaces of the glass plate, or backing the plate with either a dead surface or one with the same refractive index as the glass, and of non-actinic colour, only the latter can be said to have been adopted, and neither to be satisfactory, for although the dead surface will absorb all the light rays which reach it, it obviously cannot affect those which are reflected from the back surface of the glass, and the only advantage that packing has over placing a sheet of black paper behind the plate is that by it optical contact is obtained.

Burton's Experiments.

Some ten years ago Mr. W. K. Burton made and gave to the photographic world the results of some experiments in which he placed below the sensitive film a non-actinic one of gelatine, containing chromate of silver, which could be fixed out with hypo, leaving a clear printing negative. This was found to be fairly efficient, but so awkward to work as to be impracticable for general use.

I believe that the experiment has been tried of coating a plate with a very rapid but poor emulsion, exposing in the usual way, and then coating the plate with a thick emulsion, which it was supposed would be affected sympathetically by the exposed portions of the under film, and yield on development a good image. Who made the experiment, and what the result was, I do not know and cannot say, but venture to think that the process would prove considerably more awkward to work than that of Mr. Burton.

Double Coating.

It having been found that very little light penetrated an ordinary coated gelatine film during a moderate exposure, it was thought that if the film were thickened the chances of halation would be very materially reduced. This theory proved substantially correct, but the thick film presented difficulties and disadvantages. There was the expense of making so thick a film rich, and if it were poor—*i.e.*, if the same amount of silver that would be contained by an ordinary film were spread over the greater thickness—then an insufficient number of particles of the sensitive salt (that is, only those near the surface) would be affected to give a good result. This difficulty, however, has been got over by Mr. Sandell, who hit on the plan of coating the plate twice—a process heretofore considered impossible—first with a slow emulsion and then with a rapid one, his contention being that while the shadows were properly exposed on the upper film, the high lights would solarise it, and, penetrating to the lower, correctly expose that, and if the exposure were then increased, the high lights would entirely reverse the top film, converting it into a positive, and the greater the over-exposure the denser the positive would become, counteracting in its effects the fuller exposure of the under film; meanwhile, if the shadows were not very dark, they would, as they lessened the pluck of the "embryo" image of the upper film, form an under-exposed, and therefore plucky, one on the lower, and the weaker the one became the stronger would become the other, and the two together form a good negative.

Thus, on a correctly exposed plate, with heavy contrasts in it (and it is for this kind of view that the Sandell plate is meant), there would be on the upper film shadows with the correct exposure and high lights solarised, and on the film beneath clear unaffected film below the correctly exposed shadows, and correctly exposed film below the solarised high lights; and, in the case of the "pseudo" over-exposed plate, the shadows would be rendered by a negative lacking in contrast above and one with violent contrasts beneath, and the high lights by a positive above and a dense negative beneath; the combination of the two images in each case giving as a result a properly balanced negative of more or less density according to the amount of exposure the plate has received. In all cases little or no light would go beyond the second layer of gelatine, and, therefore, none could be reflected from the back of the glass and cause halation.

Double Coated Plates in Practice.

This, then, being the theory of the Sandell plates—the only multiple film plates at present in the market—it now remains to be seen what they will do in practice, and I must be egotistical enough to commence with a description of my own experiments, but only because I am the best acquainted with *them*. They may be interesting to some here, because made by one who knew nothing, and consequently committed every possible error of exposure, *i.e.*, of giving too little, too much, and what proved more fatal than either—singular though it may sound—a mean between the two.

On starting for my holiday this summer I determined to take a dozen ordinary Sandells with me, just to see what I could do with them. As I only got the plates the very day I started North, I was unable to make a single test exposure before starting, so had only the verbal advice of our accomplished president, Mr. Pringle, to go upon, and this I completely misunderstood, with the result that I went away under the belief that the correct way to treat the plate was to grossly—*i.e.*, many times—over-expose it, so as to reverse the top film, which was afterwards to be got rid of by stripping. As a result of the misunderstanding I managed to secure nine good negatives out of my dozen plates, and might have had ten, but for losing one through stripping when I ought to have reduced. This, it must be admitted, speaks very well for the plates. As a basis for my exposure I took what I considered a full exposure for a Thomas thickly coated landscape plate, and multiplied that by ten to make sure of over-exposing.

The first view I took was from a hill-path looking back over the town below towards the mist-covered hills beyond; a bright morning sun shining over my shoulder was clearing the mist from the mountain peaks of the Trossachs, and the whole landscape was yet hazy. I considered that a T.C.L. would have stood half a second at *f*-16, so I gave five seconds. On development the upper film darkened all over at once, and development was continued for about three-quarters of an hour, when the image was distinctly and evenly visible on the back of the plate. I fixed, and then stripped the top film off, and found a fully exposed negative on

the lower. The second plate, which was an identically similar, though not the same view, but with only 7½ sec. at *f*-22, I treated likewise, but found the image on the lower film too under-exposed to be any good, but the plate would probably have been saved had I reduced instead of stripping. As there were no great contrasts in either of these views, they were merely a test for length of exposure, and as such I will refer to them later on. As another test for length of exposure, I exposed two plates, a "Cyclist" and a Sandell, on the same subject—a group of old tombstones lying flat—under precisely the same conditions, giving the latter as many minutes as the former seconds—in each case one half, or a comparative ratio of 60 to 1. Between the two results you will see there is little to choose; the Sandell is the denser of the two, has more detail in the shadows, but is somewhat stained with the reducer. Three other views had dark foregrounds, a mountain distance, and clouds; in one the sun was in front of the camera, and shining between fir trees on either side of the picture, throwing their trunks into deep shadow; between them was a distant mountain peak, Ben Vhorlich, some eight miles off, and brightly lit clouds—in each case the clouds print well, and in this one the detail in the trunks of the fir-trees is not lost. This, I think, shows the plates' capacity for rendering contrasts.

Two other views of the same kind I unfortunately lost through giving an exposure too much for the upper film, yet insufficient to penetrate it—which seems the only thing fatal to a Sandell. Yet I believe that, had development been either proceeded with more cautiously or carried further, say, after stripping off the upper film, a printable negative might have been obtained.

Still, two others, which I exposed in a deep glen—one in which I believe a camera had never been before—with exposures that I considered sufficient to penetrate to the lower film, gave fully exposed, but good, images on the upper, which did not require reduction. All the plates were developed with Thomas's new developer, "Cyclol," which, I am told, is a mixture of hydroquinone and eikonogen, and, with the exception of the two I lost and the two mentioned as taken in the glen, development was pushed till the image appeared well marked on the back, and reduced to the required density with ferricyanide of potassium and hypo.

"Expose for the Shadows."

The old wet-collodion rule of "expose for the shadows, and let the high lights take care of themselves," seems to apply well—give the exposure that you think would best render the shadows on a plate of moderate rapidity; the high lights will then accommodate themselves somewhere in the "substrata," the great point to bear in mind being that if more exposure be given than the shadows will stand on the top film, then a *great deal* more must be given or the plate will be lost, by which is meant that, if x represent the correct exposure, then $2x$ or $3x$ will mean a flat and what would ordinarily be termed a hopelessly over-exposed plate, but if $50x$ to $100x$ be given, then there is every chance of securing a good image if development only be carried far enough.

The question will doubtless be asked, how is it possible to tell which films have been affected by the exposure, and by what symptoms can development be regulated? This is not so difficult a matter as would at first appear. As with all other plates it is best to commence cautiously, and with a developing solution of moderate strength; if the shadows remain fairly clear it is safe to conclude that the plate has not been over-exposed, and development should be carried on the same as with an ordinary plate, judging of the density by the appearance of the surface of the film, and by transmitted light, for nothing will show on the back of the plate except perhaps some very brightly lit portion—which should do so. If, however, the top film completely fogs over, the plate has been over-exposed, and development must then be continued for about half an hour, or until the image shows plainly on the back of the plate; by transmitted light it will then appear perfectly opaque.

The plate is then, in either case, fixed in the usual manner, care being taken that it is thoroughly fixed. The correctly exposed plate now presents the appearance of an ordinary negative, but the other is still opaque, and must be reduced, or if before fixing the image appeared evenly all over the back of the plate, the upper film may be stripped off—that is, if the operator feels competent to do so successfully—for it will have received such an excess of exposure as to yield a complete negative on the lower film, and render the top one superfluous. But stripping is risky work, and its only advantage is that it obviates the danger of reduction stains.

"The Scale of Densities."

A prominent theorist, Mr. Lyonel Clark, has suggested that a possible failing in the plate's action would be a break in the scale of densities, by which is meant that the upper film might be of the rapidity to correctly render the shadows and the lower the high lights, but the half-tones would act on both films and produce an area of undue density; this, however, is only a theoretical failing, for, as a matter of fact, half-tones are rendered with great beauty. Mr. Lyonel Clark further suggested that, to overcome this failing, a plate might be coated with a succession of films, each more rapid than the one below it, but this would, on the face of it, be useless, for no light would reach the lower films at all.

At a recent meeting of the Camera Club, Captain Abney described a modification of the Sandell plate to be used for spectrum photography, in which the upper film is isochromatic; the action, however, remaining to all intents and purposes unaltered.

The blue or chemical rays solarise the upper film, and are rendered by the lower, while the red rays act on the isochromatic film only, leaving the other untouched.

The scale rendering of plates thus coated is said by Captain Abney to be exceedingly good, and if by multiple coating a plate can be produced that will render by one exposure all the different colour grades of the solar spectrum in their due gradation of tone, and not only those which are visible, but also the ultra-violet and ultra-red rays which are quite invisible to the eye, it must be admitted that the multiple film plate is a step in the right direction, and that by its invention Mr. Sandell has added one more stepping-stone to those by which we photographers hope to cross the flood of difficulties that flows between us and the certain production of an ideal negative.

Gregor Grant.

PROGRESS IN PHOTOGRAPHY—A CRITICAL INQUIRY.

[Glasgow Photographic Association.]

In connexion with the late Exhibition of the Photographic Society of Great Britain it is announced that "the Council have determined to endeavour to obtain yearly such a selection from the pictures of the exhibition as shall show the progress of the art from year to year." This resolution opens up a very interesting question, viz., Is there a regular progressive movement in photography? Is the general work shown in exhibitions now better than that exhibited one, two, or three decades ago, and if so, in what direction is the improvement manifested? Is it the general mass of the work which is supposed to have reached a higher level, or can it be shown that the best results of to-day are superior to the finest photographic pictures of ten, twenty, or thirty years ago? The resolution I have read certainly infers that there is a continual progression, and in the pride of our time and of our own work we are apt to endorse the opinion without giving it much consideration. I propose in this paper to discuss the question in as fair a spirit as possible and see where it leads us. It will be necessary for this purpose to define photography, for it is a very wide term, and spreads its ever-widening wings over a vast number of operations and variety of results. It is often called an art-science, and, in a sense, correctly so, but we require a much fuller definition. There is an art photography and a science photography. These are closely associated with each other, and without the one we could never have had the other; but they are separate arts, of different natures, and must not be confounded. This distinction is not sufficiently appreciated. Any one conducting photographic operations is termed a photographer, and to the lay mind a photographer is as distinct a genus as a baker or a bricklayer, only varying in comparative ability. It will be found, however, that science and art will not mix readily, and we need not be surprised at this when we consider how vastly different are the essential principles which govern each. From the beginning of our civilisation science generally has been unmistakably progressive, and it is natural that it should be so. Nature is governed by exact forces which act and react upon each other by certain definite laws, and these are gradually being evolved by our scientific thinkers. Certain effects are remarked and noted, until by combined observation they are accepted as absolute facts. In course of time further experiments are made and fresh discoveries result.

Chemistry and Optics.

As in science generally so in photographic chemistry and optics; the original discoveries of Baptista Porta have been expanded and comprehended until now lenses of wonderful precision may be obtained for every department of photographic work. In the same way Sir Humphrey Davy's experiments on the action of light on various chemicals have been so fully developed that there is now an indefinite and ever-increasing number of methods by which the image gathered by the lens may be held and reproduced. No one will deny that there is progress in the direction of scientific photography, and there are many departments of photographic work which do not make any pretension beyond that of being scientifically useful. In this sense alone photography has been of inestimable service to the astronomer, the naturalist, and the engineer, and year by year these scientific workers are finding the means at their command more complete and useful. However, only a very small percentage of the specimens shown at exhibitions belong to any of these scientific classes, but are shown as pictures possessing more or less merit as works of art. Has the progress in this direction been as steady as in the purely scientific?

"The Late Exhibition."

Glancing over the various critiques of the late Exhibition of the Society of Great Britain, it will be noted that the *Daily Chronicle* says of the collection "that it is of greater merit than that of any previous year." The *Daily News* considers that "the level of artistic attainment

is well maintained." The *Morning Advertiser* says "there is a general improvement to be noticed in the majority of the pictures;" while the *Standard*, which prefaces its remarks by the statement that those who practise photography are usually artists, maintains "that the work is of a higher standard than that of any previous year." The *Times*, however, considers "it difficult to award to the Exhibition unqualified praise," and the *St. James's Gazette* is very severe in its criticism indeed.

The Capacity of Art and Artistic Feeling.

Not having seen the Exhibition, I have no intention of discussing its merits or demerits, but simply wish to bring the fact forcibly before you that there is a difference of opinion on the matter. Meanwhile, let us examine the nature and capacity of art or artistic feeling, and note wherein it differs from that of science. The latter we have seen to be progressive and accumulative, one generation continuing the work of their fathers, adding, as it were, fresh pages to the book of knowledge. In art, let it be pictorial, poetical, or musical, we find quite a different state of matters. Men are born with a certain capacity for appreciating that which is beautiful in form and colour, and natures which have this faculty strongly developed have from time immemorial experienced a desire to reproduce, in some way, that which in form or colour has fascinated them. These reproductions may be to others absolutely unintelligible, but are perfectly understood by natures of similar disposition or temperament of their own time and all subsequent periods. Stones may be cut with more ease now than they were 2000 years ago, but the forms expressed then were appreciated and enjoyed from the same standpoint by those who produced them as they are by ourselves to-day. It is possible that, owing to the spread of culture, there is a greater proportion of the people of to-day capable of appreciating their worth and enjoying their beauties—although this is problematical—but in any case the pleasure derived is precisely the same. And, with all our more favourable circumstances, the best products of these times cannot be excelled, rarely rivalled, in our own highly civilised and cultured nineteenth century. So, in painting, the artist has no longer to grind his own colours or prepare his own canvases or brushes; he has probably better materials; but with all the best examples of the centuries before him to study, he can hardly even hope to rival the work of the giants of his profession in past times. He cannot, like the scientist, begin where they left off, but must begin on precisely the same level. He must learn from the same open book of nature from which they learned, and his work can only reach the level of his own mental capacity.

"Ancient Art Unsurpassable."

The decorative art, of what we are pleased to term our rude Celtic forefathers, produced in the second, third, and fourth centuries of this era, and exemplified in the Ionic crosses and the brooches, sword-hilts, &c., which are to be seen in our museums, are still a wonder to us, and cannot be surpassed either for their purity of art or delicacy of workmanship by our artists of to-day. And so on—I might continue to multiply instances, Homer still stands alone and few men dream of eclipsing Shakespeare. But while thus endeavouring to show that a man must possess the greatest innate artistic instinct to produce the grandest artistic work, I do not wish you for a moment to think that I depreciate study and effort.

The most powerful faculties must be trained, and can only be fully developed by studying closely the best work that has gone before, and by earnest and constant application; but what I say is this, that a man can only appreciate or produce artistic work to the extent of his own trained artistic instinct. In photographic art the same reasoning holds good. The development of processes may give the exponent of the art fuller and more varied means of expression, but unless he feels some beauty to express no amount of scientific training or knowledge will enable him to make a work of art.

"Photography Revolutionised in the Last Ten Years."

During the last decade photography has been almost revolutionised by the introduction of the extremely sensitive gelatine dry plate. The effect of this has been twofold. It has attracted thousands of—may I call them—workers? who fancy that by purchasing an outfit, pulling a string and pressing a button, and carrying through several simple chemical operations, they will become photographers and produce pictures. They had no intention of taking any great trouble with the matter, nor do they, but in a careless hap-hazard style they produce multitudes of prints which they show to their friends, with the apology that they are only amateurs, and have not much time to spare, &c. The ease with which vast quantities of this careless work can be turned out has doubtless done much to degrade photography, and especially snap-shot photography, in the eyes of the public, but on the other hand the introduction of these extremely sensitive dry plates has put a new and as yet a comparatively unknown power in the possession of capable men, especially in landscape work. I say especially in landscape work because there are examples of portraiture done many years ago by the older processes which have never been surpassed. In the wet collodion process and in the still older calotype process, which required an exposure of several minutes in strong sunlight, there was sufficient resource to enable exceptionally clever men to produce portraits which for surface likeness and portrayal of character might almost be pronounced perfect. The strong lighting of the direct sunshine seems to show more of the real man than the softly-lighted portrait of his skin which is now so much in favour. I believe it is quite possible in photography to produce the ideal portrait which Tennyson so beautifully describes:—

> "As when a painter, poring on a face,
> Divinely thro' all hindrance finds the man
> Behind it, and so paints him that his face,
> The shape and colour of a mind and life,
> Lives for his children, ever at its best
> And fullest."

In some respects it is a pity that the old calotype method has gone entirely out of use, for it certainly possessed some qualities which belong to no other process. By its means it was possible to obtain a strength and breadth in the shadows, combined with an exquisite softness in the semitones and high-lights, which cannot be equalled, so far as I know, by any of the processes in use to-day. The process certainly had some strong points, and these were fully taken advantage of by a fellow-countryman of ours—D. O. Hill, R.S.A.—who, during the years 1843 to 1845, produced a series of hundreds of portraits, which artists, from Sir Frederick Leighton downwards, declare to be among the finest specimens of photographic work. I have here two volumes of these portraits, which I am proud to possess, and which have been shown to you before; but, as I can look over them with fresh pleasure and benefit every week, I make no apology for showing them to you again. These portraits bear the true stamp of the power of the worker, that of his own individuality. As experts can certify the unsigned works of the masters of painting, so these can be recognised as the product of one mind.

This is only one example. We have had other great portrait photographers, whose comparative merits it is not now my object to discuss. Mrs. Cameron, for instance, of whose portraits of Tennyson we are at present hearing a great deal, and who lived and worked in the days of wet collodion, did splendid work, which also bears her own personal imprint stamped in the picture, whether it be on the mount or not.

"Method."

The method is a comparative trifle to the artist; so long as it is capable of adequately expressing his feeling, he is content. But while these slower methods were sufficient for the capable portraitist to express himself more or less fully, the more rapid process has enabled the landscape photographer to work in a manner which was before impossible.

The poetry of the swaying reed, the rippling water, and the rolling cloud, is no longer beyond his effort, while in the snapping of a hand camera at a moving figure there may be more scope for artistic composition than in the most careful posing, and the possibility of obtaining a perfect result is certainly much greater. The simplicity of the working of modern methods has, as I have already said, attracted an enormous number of disciples, with this good result, that, among the multitude whose work is beneath consideration, there is bound to be a certain proportion of highly capable men, who, but for the simplicity of the manipulation, would never have touched photography at all, and, if the general work shown in our exhibitions is improving, I attribute it partly to the fact that a greater number of capable men are taking part in them, men of artistic feeling and training.

Indeed, the manipulation has now become so simple—thanks to the scientific workers—that, with a few lessons and several weeks' experience, there is no reason why any one, with an artistic knowledge and an adaptive disposition, need not make as perfect pictures as a photographer of many years' standing.

I have seen work done, within four works of the purchase of a camera, by a gentleman who before then knew absolutely nothing of the manipulation of photography, which would stand in the front rank of any of our exhibitions, and his success did not greatly surprise me. For twenty years it had been his delight and his profession to study form and composition, and to express them in other forms of art work. The technical manipulation is nothing compared with the knowledge of what goes to make a picture. The true artist will make use of the methods which the scientist has prepared for him, utterly indifferent as to the action of the chemicals; he will use the materials which serve most fully to express his feeling. Art has been defined as "Nature seen through a tem-

perament," and I think there is a great deal of truth in the definition. It is a truth which is very often forgotten, or not sufficiently understood, by scientific minds. The eye to them is simply a lens, the retina an exact and precise mirror. They make no allowance for the quality and temperament of the brain behind the retina. The impression the artist endeavours to reproduce is that which his brain sees on the retina, or so much of it as is of interest to him, and it is this selection of his work which stamps it as his own, and makes it different from that of another. If two artists of equal capacity happen to be attracted by the same piece of landscape, and from exactly the same point make a drawing of it, the results, while of equal merit, will be perfectly different. So it ought to be, to a certain extent, with photographers who study to reproduce their own individual expression. What I mean is very well expressed in the sonnet which appeared on the title-page of the *Germ*, the organ of the Pre-Raphaelite Brotherhood :—

> "When whose merely hath a little thought
> Will plainly think the thought that is in him—
> Not imagining another's bright or dim,
> Not mangling with new words what others taught:
> When whose speaks, from having either sought
> Or only found—will speak, not just to skim
> A shallow surface with words made and trim,
> But in that very speech the matter brought.
> Be not too keen to cry, 'So this is all!
> A thing I might myself have thought as well,
> But would not say it, for it was not worth!'
> But ask, 'Is this truth?' for 'tis still to tell
> That, be the theme a point or the whole earth,
> Truth is a circle perfect, great or small."

Even in the copying of paintings it is possible for the personal element of the reproducer to appear in his work. I shall quote from an article by Mr. Horace Townsend, on the exhibition of Mr. Hollyer's work at the Dudley Gallery, which seems to me to have been written with considerable insight and judgment.

In addition to the speed and simplicity of the gelatine dry plates, there is another quality which has enabled landscape photography to progress, and that is the more correct rendering of tone in small detached portions of light. In collodion plates every little spot of lighter shade had a tendency to become a sparkling white, and the effect destroyed all feeling of atmosphere and breadth which the picture might otherwise have possessed. Thanks to the gelatine plate, therefore, I consider that artistic landscape photography has progressed much during the last decade, and that the results produced by the best workers of to-day are superior to those of twenty years ago.

I have not taken into account the printing processes in this review of the progress of photography because, while there have been quite a number of delightful methods recently discovered, there has been from comparatively early times a variety of processes suitable for artistic expression, and while there is now a greater number to choose from they have not to any extent extended the possibility of artistic work. But for the lack of permanency of the plain paper silver printing, nothing could be finer, while carbon printing, which must now be considered an old process, is capable of such a variety of treatment that almost any result whatever may be produced by it.

The great matter, as I have already said, is to know how to use the methods when we have them.

Few men attain distinction in more than one department of work, and it will be generally admitted that the scientific capacity and the artistic temperament are seldom found in the same individual to any extent. One scientific man of considerable eminence is reported to have said that photography would be a delightful pursuit if it were not for the pictures, and I have heard several camerists say a fervid Amen to the opinion. They are wise men who can analyse themselves to this extent; they would be paragons if they took it to heart and refrained from sending their pictorial results to exhibitions. Their sphere of work, a most important one, is to perfect the materials, that others need not trouble themselves about the matter.

It seems evident, then, that for a photographer whose aim is to make pictures, the training should be artistic, not chemical. Let him study the works of the accepted masters in regard to tone and composition, balance of light and shade, and execution. Let him study to discover wherein lies the beauty of these pictures, and then he will see nature with fuller eyes, and it will be his aim to reproduce the new beauties disclosed to him, and not merely to obtain a permanent image of the reflection on a soulless mirror. "Faultily faultless, icily regular, splendidly null, dead perfection, no more." To sum up the result of this investigation I would say that the science of photography has been a constant progression, with the natural result that the increased facilities have enabled men of equ capacity to express themselves more fully, and thus to produce fin work. Scores of men now practise photography for every unit who d so a very few years ago, and there are, consequently, more good worke than formerly, and more good work to show; but the progress has be intermittent, and while the science of photography will continue steadi to progress in the future, the art will rise and fall as the men of mo than ordinary power and genius are born and die away.

J. Craig Annan.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 2	Camera Club	Charing Cross-road, W.C.
,, 2	Dundee Amateur	Asso. Studio, Nethergate, Dund
,, 2	Peterborough	Museum, Minster Precincts.
,, 2	Richmond	Greyhound Hotel, Richmond.
,, 2	South London	Hanover Hall, Hanover-park, S
,, 2	Stereoscopic Club	Brooklands Hotel, Brooklands.
,, 3	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 3	Bolton Photo. Society	10, Rushton-street, Bolton.
,, 3	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 3	Exeter	City Chambers, Gandy-st., Exet
,, 3	Hackney	206, Mare-street, Hackney.
,, 3	Herefordshire	Mansion House, Hereford.
,, 3	Keighley and District	Mechanics' Institute, North-str
,, 3	Lewes	Fitzroy Library, High-st., Lewe
,, 3	North London	Wellington Hall, Islington, N.
,, 3	Oxford Photo. Society	Society's Rooms, 136, High-stre
,, 3	Paisley	9, Gauze-street, Paisley.
,, 3	Rochester	Mathematical School, Rochester
,, 3	Rotherham	5, Frederick-street, Rotherham
,, 3	Sheffield Photo. Society	Masonic Hall, Surrey-street.
,, 3	York	Victoria Hall, Goodramgate, Yo

,, 5	Tunbridge Wells (Annual)	Mechanics' Inst., Tunbridge We
,, 6	Brighton and Sussex	
,, 6	Cardiff	
,, 6	Croydon Microscopical	Public Hall, George-street, Croy
,, 6	Holborn	
,, 6	Leamington	Trinity Church Room, Merton-
,, 6	Maidstone	"The Palace," Maidstone.
,, 7	Hull	71, Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

December 22.—Mr. A. Mackie in the chair.

Mr. A. Cowan showed two transparencies he exposed in accordance with t Hurter & Driffield method of speed determination, one of them being twen two times faster than the other. The exposure was equalised by placing t frames at different distances from the illuminant, and the resulting ima showed as practically equal.

Mr. E. W. Parfitt showed several outdoor portrait studies, taken with t front combination of a cabinet portrait lens, the focus of the former be eighteen inches.

A discussion arose as to a statement that with some developers the ima during development, appeared at the back of the plate as a positive, and w others as a negative.

The Chairman remarked that he had always failed to reduce all the sil in a plate by any method of development.

Mr. P. Everitt thought it might be done with ferrous oxalate.

Mr. T. E. Freshwater showed photographs of the Himalayas, taken w both ordinary and isochromatic plates, sent him by a gentleman who c sidered that the latter plates did not give any advantage in the result photographs.

Messrs. Debenham and Bolas, however, pointed out that there was a decid superiority in the results as given by the isochromatic plates.

Mr. Peter Mawdsley was present at the meeting, and, in the course o few remarks as to the state of photography in America, said he thought th in regard to original research, American photographers were a long way behi the English. Americans were great believers in the virtues of develop formulæ.

Mr. P. Everitt, as the delegate of the Association on the Affiliation Co mitteee of the Photographic Society of Great Britain, gave details of t progress of the scheme, and gave it as his opinion that that scheme was wort of support, as he thought great benefits were likely to result from the propo "technical albums" which the Affiliation Committee were endeavouring establish.

The Association decided to join in the latter movement.

Hackney Photographic Society.—December 20, Mr. R. Beckett in the chair.—The Hon. Secretary made an appeal for voluntary financial assistance for Mr. Weir, a professional photographer, whose cause had been taken up by *Photography*, which was responded to. Some gummed labels (numbered) were shown and approved of, made by Vevers. The HON. SECRETARY announced that the Society had become affiliated to the Photographic Society of Great Britain. This was heartily received. Mr. W. L. Barker and Mr. Wire handed round work done on Paget print-out opals and plates respectively, fair results being obtained. Mr. Cross showed a negative which had black marks over it. The CHAIRMAN said these were due to metallic contamination which Mr. Cross thought was the case. Mr. Hudson showed a taper holder, marked in inches, which he used for burning magnesium ribbon. By this method he could mark off exactly the quantity of ribbon he wished to use. Mr. Paget (of Mr. C. A. Rudowsky's) then showed and explained the working of their electrical retouching apparatus. The vibration caused by the electricity made stippling over the film which facilitated the retouching. Owing to the absence of a proper negative the full value could not be estimated, but it will later on be tried. Mr. Paget showed a flash-lamp Mr. Rudowsky was bringing out, in which the powder was blown through upwards, and a continuous exposure of twelve seconds could, at will, be obtained. After this, negatives and transparencies on mica were passed round. They were not yet on the market—owing chiefly to their high price—but there was a great advantage, as, being so very thin, they could easily be printed from either side. In answer to a question, Mr. Paget said they would not chip.

Leeds Photographic Society.—December 12.—The following gentlemen were elected the officers of the Society for the ensuing year:—*President:* Mr. J. H. Walker.—*Vice-Presidents:* E. H. Jacob, M.A., M.D., and Mr. S. A. Wrigglesworth.—*Hon. Lanternist:* Mr. H. P. Atkinson.—*Hon. Librarian:* Mr. T. Butterworth.—*Hon. Treasurer:* Mr. T. W. Thornton.—*Hon. Secretaries:* Messrs. Herbert Denison and Robert Steele.—Mr. GODFREY BINGLEY introduced a discussion on *Film Photography*, first describing the composition of celluloid films, and the advantages on account of their lightness and small space occupied in comparison to glass plates, besides the advantage in not being liable to break; but the chief part of his remarks applied to the Eastman films and roll-holder used in the Kodak. His experience had been rather unfortunate, while he secured many good negatives. He also had some with electric markings, some with black bands, others with telegraph-wire-like markings across, scratchings, and tearing across, the causes for which he could not well explain. Mr. Smith, representative of the Eastman Company, was present, and, with his characteristic energy, combated some of the complaints, and showed negatives and prints from their films which were certainly very fine. While admitting failures at times, he stated that in all cases of defects the Co. made any compensated by supplying a fresh roll, which was corroborated by Mr. Bingley. Mr. Smith also stated that improvements were being made, and that films in 1893 would be as near perfection as possible.

Rochester Naturalists' Club (Photographic Section).—December 20, Mr. C. Bird in the chair. Mr. J. C. BOON gave a demonstration on the *Wet-Plate Process*. Mr. G. E. Randall offered to give a silver medal for the best print, to be taken by the members in the neighbourhood of Rochester.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE NEW METHYLATED SPIRIT.

To the EDITOR.

SIR,—Seeing your remarks in the ALMANAC just issued on the absence of any data with respect to the effect of mineralised methylated spirit in gelatine emulsion, I should like to say that, so far as I have tried it, it does not appear to have any harmful effect whatever, and that it is quite impossible to distinguish between plates coated with emulsion containing mineralised spirit, rectified spirit, or without spirit entirely.

In proof of this I made the following experiment, which may be of interest to some of your readers. An ordinary bromo-iodide emulsion was prepared, boiled for twenty minutes, and washed as usual. To two ounces of this emulsion one drachm of rectified spirit was added. To another two ounces (from same batch) was added one drachm of mineralised spirit. Plates coated with these emulsions, and exposed one immediately after the other, and developed in the same dish, are identical in every respect.

I enclose two plates for your inspection. It would perhaps be as well to add that the above emulsion is of a very robust character and rather slow, and capable of withstanding some rough usage. Whether the presence of mineralised spirit in a delicate, ultra-rapid emulsion, prepared with alkali, would be as harmless, I cannot say, but with the above the effect is *nil*.—I am, yours, &c., THOS. HADDOCK.

27, *Chapel-street, Leigh, Lancashire, December* 23, 1892.

"AN INDIAN STUDIO."

To the EDITOR.

SIR,—In the JOURNAL which reached me to-day I see a letter from Mr. R. W. Robinson regarding Mr. Bhedwar's pictures of the *Rite of Initiation of a Parsee Priest*, and giving *his* reasons why they did not appear at the recent Exhibition of the Great Britain Society.

Now, I was with Mr. Bhedwar for over one hour, during which time I gathered my impression that the pictures in question had been sent home for the principal Exhibition of the year. Mr. Bhedwar certainly made no remarks to lead one to suppose that he entertained such very unfriendly feelings towards the parent society as Mr. Robinson puts into his mouth.

The quarrel over the Exhibition of last year was originally a very petty one, and I am bound to say that from what I read in the several JOURNALS, I rather sympathised with those who left the society, but since then the continually recurring sneers and rude remarks have gone far to alter my opinion, and I am rather inclined now to congratulate the society on the clearance.—I am, yours, &c., YOUR CORRESPONDENT.

December 7, 1892.

To the EDITOR.

SIR,—I find from your remarks on Mr. R. W. Robinson's letter in your JOURNAL of the 18th ult., that you have been at pains to draw from your correspondent a reply conflicting with the statement made by the author of "An Indian Studio." The real facts how the latter contributor got at this information would set all your doubts to rest, and save my friend, Mr. R. W. Robinson, from any further trouble *re* the question of exclusion of my *Naver* from the Pall Mall this year. There is no doubt that at first the *Naver* was intended for the Pall Mall Exhibition. When this series was completed, some art critics of local newspapers took a very favourable notice of them, upon which they were sent to some distinguished personages, such as H.E. the Viceroy, and H.H. the Gaikwar, to be seen. At that time a note at foot of the pictures in pencil was affixed to the effect, "Specially done for Pall Mall Exhibition, London." Some how or other, when these pictures were returned, the above remark was not erased but allowed to remain as it stood. In all truth, this remark must have been read while inspecting the pictures in question by the author of "An Indian Studio" when he came to have an interview with me. But it was very long before the visit of this gentleman that I had requested my friend and agent, Mr. R. W. Robinson, to withhold my work from the Pall Mall Exhibition upon certain grounds of my own. Before I conclude, I hope this explanation would sufficiently exonerate Mr. R. W. Robinson from any wrong imputations that might have come to be alleged against him.—I am, yours, &c., SHAPOOR N. BHEDWAR.

[This correspondence here terminates.—ED.]

DIPPING-BATH DEVELOPMENT.

To the EDITOR.

SIR,—With reference to Mr. Meldon's letter on the above subject in your last issue, I should like to refer you to a paper on "An Apparatus for the Development of Photographic Plates without the Use of a Dark Room," published in the *Journal of the Society of Chemical Industry* for January, 1891.

I there described an apparatus of the dipping-bath form, capable of containing several plates, and which has the advantages referred to by Mr. Meldon. The bath is not in the market, but as it is not patented, any manufacturer is at liberty to introduce it. I enclose a copy of the paper.—I am, yours, &c. ALEXANDER WATT.

Liverpool, December 19, 1892.

LOCAL REDUCTION.

To the EDITOR.

SIR,—On reading your article on "Local Reduction of Negatives" in last week's JOURNAL, I was rather surprised that you made no mention of the alum and citric acid clearing solution. I have on various occasions tried the methods you mention, but, if you will pardon my saying so, I do not think one of them, for general usefulness, can "hold a candle" to my favourite. Space will not permit me to mention half the miscellaneous subjects that I have successfully treated by local application of the clearing solution, such as bringing out the buried inscription on an over-developed tombstone or such like subject, reducing the density of windows and other objects in interiors which happen by contrast to be too pronounced, or improving sky or water in landscape.

But it is in portraiture that it excels, for by its means a big ear, or protruding lip, high cheek-bone, bald head above a sunburnt face, or (in case of a lady in evening dress) the white neck below a sunburnt face, may all be made to lose their undue prominence and be brought into harmony. And, further, I have even, by applying it only to what should have been the shadow side, made passable things of negatives that would otherwise have been useless owing to their flatness and want of effect; in fact, there is a very wide scope for any one with a little artistic skill, particularly if accustomed to use the brush. The reason, no doubt, many have failed is that they have attempted these things upon a wet surface, and any great amount of success in that way is utterly impossible for obvious reasons.

Some may be led to remark that this method is all very well for negatives of a high colour, but that with so-called colourless negatives it is useless. But I would ask any one to try such a negative, and to follow your recommendation, and get a print off before being quite sure that the printing quality has not been changed; for, after trying hundreds of various kinds, I have found that in almost every case they are amenable

to treatment if they have not already been through the clearing solution.

One word as to method of procedure. I perform this operation in daylight, having the solution in a white porcelain dish, and water in another dish, in case it is needed. I use an old sable brush—one that is just too far gone for spotting prints does very well—and, dipping this into the solution, I touch very carefully the parts to be reduced. If the action is slow, I lay the negative across the dish, and proceed to treat another in the same way, just watching to keep the places moist until the desired effect is attained. I then slip the negative into the dish, and flow the solution once or twice over it, which is quite sufficient to remove all traces of the local treatment. I then get it washed as quickly as possible. Of course, if any further local treatment is found to be necessary after the surface has become wet, the negative will need to be dried before repeating the process.—I am, yours, &c., T. S.

December 20, 1892.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," 2, *York-street, Covent Garden, London.*

T. H. DE PIEFFE.—Received.

C. H. YOUNG.—We note your remarks.

HERTS.—We did not retain the address.

GRAYSTONE BIRD.—The slide is excellent, and comes out very well on the screen.

S. W.—The scratches on the prints are caused by particles of grit on the surface at the time of burnishing.

"BEAUCHAMP" is requested to communicate with Mr. H. Wilkinson, Churchgreen Studio, Harpenden, Herts.

W. DAVEY.—The only manufacturers of celluloid in this country that we know of are the British Xylonite Company, Homerton, E.

A. THURSTON.—Bleaching the image with bromine water and redeveloping does not by any means confer as much density as bleaching with mercury and darkening with ammonia.

C. A. SCHMELDT.—The best hypo eliminator is water. The action of the so-called "hypo eliminators" has so often been described, and their disadvantages pointed out, that we can only refer you to back volumes.

A. LARRANCE.—It would certainly be a waste of time to clean off the spoilt negatives with the idea the makers of the plates will purchase the glass for recoating. It is more than doubtful if they would accept it as a gift.

C. WILTON.—We cannot recommend a gas stove of the form and size named for heating a studio of such dimensions. A good large coke stove, or even two, would be necessary to render the building at all comfortable in weather such as that we are now having.

E. J. M.—The object-glass (or glasses if more than one) for a focussing finder should be achromatised. For an eyepiece, the most convenient is the non-inverting one in ordinary pocket or terrestrial telescopes, although we have used the Ramsden eyepiece with success.

WARDEN.—1. Unless the slides are larger than the usual size—three and a quarter inches—there will be no advantage in a five-inch condenser. On the contrary, it will involve a loss of light. 2. Amidol will answer. 3. For bromide enlargements the ferrous oxalate is the developer most used by professionals.

RONALD.—A studio eighteen feet long and ten feet wide is not at all adapted to taking groups in—that is if the number included in the groups exceed two or three persons. Equal illumination over the whole of the figures will not be obtained, and only very wide-angle lenses could be used, and these would give violent perspective.

NOVOCASTRIENSIS.—The negatives certainly appear to have been under-exposed; but we should like to know the temperature of your developing solution before pronouncing any decided opinion. Chemical action, as we have often pointed out, is accelerated or retarded by the rise or fall in the temperature of solutions.

W. RESKER.—You are rightly informed that the argentometer is not an accurate register of the strength of the sensitising bath; but, within certain limits, it is sufficiently reliable for all practical purposes—that is, providing the bath contains no other salt than nitrate of silver, and that obtained by double decomposition from the paper.

J. MARSHALL.—You are only one of a vast number whose eyes are dissimilar in focus. We cannot tender you any advice in the matter, nor can we offer an opinion as to the ability of the firm mentioned to treat the case. As you can see to retouch sufficiently well without spectacles, it would be better to do without them until compelled to wear them.

A. R.—The cause of the cold and inky-like tones in the pieces of enlargements sent is under-exposure and forced development. The remedy is simply a longer exposure. In some of the examples the exposure given might well have been doubled, or even tripled, without fear of its being overdone. Instead of working by set rules, try and profit by experience.

J. B. CURRY says: "I am about to take out a provisional specification of a patent for an improvement in connexion with photography. Can you tell me if, when a provisional specification has been accepted by the Patent Office, I can, without invalidating that protection, describe my invention to a firm who are likely to purchase it?"—Yes, that is one of the chief objects of a provisional specification.

O. CARTER.—Nothing can now be done with the Daguerreotype but washing it in a weak solution of cyanide of potassium, giving preferential treatment to the end most stained. We warn you, however, that unless you are expert at such work the portrait may become obliterated entirely. A delicate Daguerreotype cannot stand the evidently coarse treatment to which this one has been subjected, judging from your letter.

A. R. C. wishes to try making burnt-in enamels, and asks "where the proper kind of furnace and muffles are to be obtained?"—Doulton & Son, Lambeth, supply all kinds of furnaces and muffles. Fletcher & Sons also supply very convenient furnaces for the purpose in which gas is the source of heat. For working on a small scale, a furnace of this description will prove more convenient than one consuming coke or charcoal.

A. M. M.—The figures represent the spherical aberration of the individual lenses, neglecting thickness and worked out to the first approximation. If the figures given be multiplied by $\frac{y^2}{f}$, they will give the difference in focus of the central and marginal rays where y is the distance of the marginal ray from centre, and f the reciprocal of the focus.

*** "*Editorial Table*," *and several other communications unavoidably held over, in our next.*

WEST LONDON PHOTOGRAPHIC SOCIETY.—January 3, Technical Social Meeting.

PHOTOGRAPHIC CLUB.—January 4, *Collodio-Chloride Printing.* 11, Members' Open Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 5, *Exposures*, to be opened by Mr. A. Cowan. 12, Ordinary Meeting. 19, Monthly Lantern Night.

THE inaugural meeting of the Harringay Photographic Society will be held on Thursday, January 5, at the Endymion Restaurant, adjoining Harringay Park Station, Midland Railway, commencing at eight o'clock, when Mr. Dudley Towers will take the chair. For further particulars, apply to Mr. C. Frith, 8, Cavendish-road, N.

HEMERY'S MEDALLION GROUPS.—Messrs. Marion & Co., of Soho-square, are introducing seven different arrangements of Hemery's medallions for portraiture. Each medallion group has its appropriate set of masks for making the negative, also the masks and discs for printing. Mr. Hemery has adopted the novelty with gratifying results, and Messrs. Marion anticipate that it will be welcomed by photographers generally. The cost is comparatively small.

THE Durham City Camera Club will hold an exhibition of members' work in the Shakespeare Hall, North-road, Durham, on Tuesday, February 14, 1893. The following classes are open only to amateur members of the Club:—General (landscape, architecture, &c.).—Set of six direct prints, 5×4 and under, mounted on one mount. General (landscape, architecture, &c.).—Set of three direct prints, half-plate and above. Portraiture or group.—Set of three direct prints, any size. One enlargement print from original negative to accompany exhibit. Set of four lantern slides. The following class is open to all: Set of six lantern slides. In this class a silver and bronze medal, given by the Mayor of Durham, will be at the disposal of the Judges. The Hon. Secretary is Mr. R. Hauxwell, The Avenue, Durham.

FORTHCOMING EXHIBITIONS.

THE LANTERN RECORD.

CONTENTS.

COMMON GAS FOR DOMESTIC LANTERN ENTERTAINMENTS.

VERY numerous indeed is the class who, desirous of giving a quiet parlour entertainment to a few friends, eschew the illumination of the lantern by the three or four-wick petroleum lamp on the one hand, with its often unpleasant smell and its unremittingly required attention, and, on the other, the oxy-hydrogen limelight, which does not always lend itself to an impromptu exhibition.

To such the use of common domestic gas would prove a boon, provided that it gave such an intensity of illumination as would equal, or even nearly equal, the oil lamp, and enable a disc of six or seven feet in diameter to be produced. As to the facilities implied in the employment of house gas for this purpose there can only be one opinion. The lantern is mounted on its stand, the tubing is connected with the gas bracket, and all is ready.

The poverty of gas as a means of lighting is the paramount drawback to its being used; but, when by such means as those about to be described it is enriched, then does it serve the purpose very well, as we have had frequent occasion to determine.

First of all, concerning the burner to be employed. Every connoisseur in gas lighting is aware that there are now several in the market by which the maximum light capable of being given by gas is obtained, but unfortunately the form of the flame is not suitable for the purpose now under consideration.

After trying argand burners of various dimensions, we give preference to a pair of small-sized fishtail burners placed one in front of the other and separated from each other to the extent of about an inch. They must have their flat sides of the flame towards each other, care being taken that the flames do not come into contact. A special feature consists in there being a reservoir placed over the flames in such a manner as to heat the reservoir slightly in order to vaporise a supply of hydrocarbon placed therein. We have tried several of the hydrocarbons, such as oil of turpentine, naphtha, &c., with success, as the gas, which must be made to pass through this reservoir, becomes so enriched as in some cases almost to dazzle the eye.

But the best of all the substances is one known in commerce as albo-carbon, which sells at a few pence per pound. In our lantern burner there is a tap by which the proportion of the vapour to be mixed with the gas can be regulated to a great nicety, the correct adjustment being that at which the flame gives no smoke, which would be the case were the carbon in excess. When once adjusted, no further attention is required.

The increase in the luminosity caused by this is so great, that if the albo-carbon tap be closed, and the gas from the mains alone be allowed to pass, the disc on the screen is instantly rendered comparatively dark.

Of course this is not recommended as a substitute for the lime light, when there is a large audience and the best effects possible are desired to be attained; but it forms a convenient means of utilising common gas under the circumstances already mentioned, viz., when an impromptu entertainment is desired to be given to a few friends assembled in one's parlour, and when it is not considered expedient to offend the olfactories by the usual four-wick petroleum lamp or to induce a *soupçon* of danger by the introduction of oxygen, whether stored in a bag or compressed in a bottle.

LANTERN NOTES AND NEWS.

WE understand that at the recently opened Trafalgar Square Theatre it is proposed to utilise the optical lantern for projecting pictures upon the drop scene between the acts.

* * * * *

WE should be glad if Secretaries of Societies would send us the dates of their lantern evenings for inclusion among our fixtures, as well as particulars of lantern-slide competitions which may be in progress.

* * * * *

LANTERN entertainments in and around London do not excite anything like the interest among the general public which is the case with similar exhibitions given in many of the large provincial towns, and the reason for this we do not hesitate to set down as the failure on the part of photographic societies to undertake such entertainments on a sufficiently extensive scale, and to give them the necessary publicity beforehand. Among the London societies are some of the most successful makers of slides, and we are sure that with a little energy and enterprise it would be possible for several of them to organize lantern entertainments at which the outside public, for a moderate admission fee, would attend in numbers sufficiently large to make the venture remunerative.

* * * * *

CONVERSING recently on this subject with Mr. George Mason, he informed us that the series of lantern lectures which has lately been delivered at the Glasgow Institute of Fine Arts by well-known photographers attracted uniformly good audiences—as much as £20 and

£30 being taken for admission on some evenings. The series was well advertised beforehand, and was almost exclusively patronised by the general public. The subjects chosen were of interest to popular audiences, Mr. Mason himself, as we remarked in THE JOURNAL last week, treating of *Mary Queen of Scots; Her Palaces and Prisons.* The outside public, as a rule, gets comparatively few opportunities of observing to what a pitch of excellence and beauty the production of lantern slides by amateur workers has been brought.

* * * * *

AT the meeting of the Manchester Society on September 8 Mr. Alan Garnett introduced a substitute for the lime cylinder, to be used for the oxyhydrogen light. It was composed of a preparation of magnesia, in the form of a small disc (about the size of a sixpence); a platinum pin in the edge enabled it to be fixed in a suitable holder on the ordinary lime piu. Mr. Garnett stated he used it with a blow-through jet; with a mixed jet it did not give as good a light, the reason of which he could not explain. When the light was once adjusted, no further attention was required, and the disc was unaffected by the ordinary atmospheric moisture when not in use, qualities which were of great advantage over limes. As far as Mr. Garnett could at present tell, the substitute was fairly durable, and each disc would last a considerable time. A rough trial was made in the lantern with the new disc against lime, a blow-through jet being used, and, as well as could be judged, the lights were equal, some being inclined to award the new light superiority in purity. We believe it was proved years ago that, under proper circumstances, a more brilliant light could be obtained with the magnesium disc than with the ordinary lime. Decidedly its imperviousness to atmospheric influences is a quality in its favour.

* * * * *

AN annual exhibition at which lantern novelties could be fully represented is still a *desideratum.* At the present Photographic Society's Exhibition in Pall Mall only one lantern is shown, and this notwithstanding the fact that the opening of the exhibition is practically contemporaneous with the opening of the lantern season. Why is this? It is hoped that in the new premises, which it is stated the Society will next year occupy for the purpose of its annual exhibition, a separate apartment will be reserved for apparatus, among which there will be a good display of lanterns and accessories. According to the present system, the apparatus has necessarily to play an absolutely unimportant part.

* * * * *

FOR those who, whether from choice or necessity, have to make oxygen for themselves instead of obtaining it compressed in cylinders as so many now do, the proportions for an oxygen mixture, given a few years since by Mr. E. Holland, will be found to possess certain advantages. It consists of—

Chlorate of potash	8 parts.
Oxide of manganese	2 „
Common salt	1½ „

This, when in the retort, responds quickly to the variation of the heat applied, and yields a large proportion of gas.

PROGRESS OR FASHION?

How much of the present design in optical lanterns and projection apparatus is due to progress or influenced by fashion?

This is a question that may well be asked in the first number of a Lantern Supplement; and, on looking back with an experience in the lantern world of more than a quarter of a century, it seems to me the answer may very fairly be said to be the greatest share is "Progress." The marked difference of late has been in the gravitation of the special designs, or those possessing most originality, to either extreme, viz., "The Giant" or "The Pigmy."

The large objectives (now recognised and admitted, after much question and adverse criticism, to be superior for long distant projection) necessitated modified apparatus, for the weight of the fronts, when extended to get the correct focus, needed supports, hence the greatest departure in design of dissolving view apparatus, as carried out for Sir David Solomon, which followed the appearance of the Triple Rack, the "Doowra," and the "Perfect" Triple lanterns. Miniature lanterns have been to the fore, and various designs have been placed on the market to secure efficiency when working, and yet be convenient for personal carriage. Notably the lanterns with fronts to reverse and pack inside the body; while those which slide in the body (the outcome of suggestions of Mr. Andrew Pringle) prove to be practical as well as portable.

Camera bellows fronted lanterns are becoming popular, and here we have a revival of a very early type of lantern, and one which in America has been in use for years. From the same country came the demand for large-size front lenses, and, when one or two popular lecturers (notably Mr. French and Mr. Snazelle) exhibited what could be done on a large scale at the Crystal Palace, and elsewhere, our own representative lecturers followed suit.

The developments of apparatus in this country (as is usual when once the requirements are made known) have been marvellous, and it is only necessary to look at the Almanacs and Year Books to see what great alterations (and probably advancements) have been made in lanterns during the past few years. The perfection of detail follows as a matter of course as long as users of apparatus will purchase and so encourage makers to invent or improve.

Simple apparatus of the old order can no doubt produce good results in the hands of operators who have manipulative skill and possess the necessary coolness; but there are so many who cannot help getting excited when in the presence of an audience, and these find the modifications a great boon. For instance, what is more disconcerting than for an accidental touch of the back of the jets to upset the centering of the light, and for the operator to see the disc on the screen partly obliterated? The improved supports and clamping pieces to jets or vertical rack work makes this sort of contretemps an impossibility. So again with the adjustments to fronts of biunial and triple lanterns. The new designs have originated because the old were "tried and found wanting" at times.

With the extended use of the electric light, greater attention has been paid to projection apparatus, and, although most of the improvements follow on the lines of apparatus in use twenty-five years ago, certain departures have produced in the result a polariscope and a microscope that can be distinctly stated to be a decided "progress."

Thanks to the experimental and practical work of the Rev. P. R. Sleeman, Professor Sylvanus Thompson, Mr. Lewis Wright, Sir David Salomons and others, results can now be obtained when illustrating the phenomena of polarised light of almost equal excellence and certainly with most of the practical value of that obtained by the late Mr. Spottiswoode, who had the unique advantage of a magnificent polarising prism of Nicol's form. When Iceland spar became so scarce in large size of necessary purity, a substitute had to be found, and the elbow polariscope, with its polarising bundle of glass, not being so convenient as the direct working form, the arrangement of making the artificial glass prism was tried, and after that the double reflecting polariser used. This permits of rays entering and leaving the polariser in a horizontal plane, and gives sufficient light for all optical experiments in connexion with polarised light. With the microscope, the improved objectives, complete set of condensers for the various powers, parallelising lens, and convenient adjustments to all the necessary portions of the apparatus show in the result a distinct advance on the "Duboscq" projection microscope and others of that class, while the simple instrument with its one substage condenser for using with the objectives of the table microscope gives results in advance of the tube form of microscope of old, with its uncorrected powers, besides being more convenient to use.

The condensed-gas system, with automatic regulation, has almost entirely shelved the gas bags, while the cheapening of oxygen by patent and other processes has done away with the necessity and trouble of making one's own oxygen gas. The high pressure that can be safely used has given a power that has been availed of in making mixed gas-jets to give a higher illuminating power; and here, again, is progress, for "light, more light" is the requirement of demonstrators using projection apparatus. The "Focus" incandescent lamp of 100-candle power is a capital illuminant for those who have the electric current laid on in their houses, and when one thinks of the great trouble it was to produce an electric light in the old days we have here a distinct advance and a saving of labour, for, by simply switching on the current when once the connexions are made, a nice disc of moderate size can be produced, and photographs projected on the screen large enough for any number of friends in a drawing-room to see the detail properly. This, without the drawbacks inseparable from paraffin-lamp illumination.

To sum up, no doubt there is a certain amount of fashion in the size and design of lanterns, and the form of accessory apparatus, but the improved capabilities of same point to the fact that "progress" has not been slumbering.

G. R. BAKER.

LANTERN CONDENSERS.

[Stereoscopic Club.]

When a beam of parallel light, A A (Fig. 1), falls upon a convex lens, he rays will be bent towards the centre and made to converga approximately to one point *f*, which is called the principal focus. If, on the

Fig. 1.

other hand, a diverging beam of light proceeded from a point at *f*, the rays could be traced back—that is to say, they would, after leaving the lens on the other side, proceed parallel to A A.

If the point of light be brought nearer to the lens than the principal focus *f*, as shown at A (Fig. 2), the lens would have too much work to

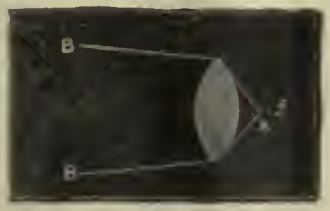

Fig. 2.

perform to send the rays parallel, and they would proceed from the lens still divergent as B B, though not as much divergent as before they entered the lens.

When the point of light is outside the focus, as at A (Fig. 3), the rays on the other side of the lens will meet at some point B (approximately), and if the point of light be moved to B the rays would meet at A; so we

Fig. 3.

see that A and B are reciprocal, and are called the conjugate foci, one having a distinct relation to the other. As the point of light A (Fig. 3) advances towards *f*, the conjugate B will move away from the lens on the other side, but not in the same proportions as A advances, for the longer focus always moves more rapidly than the shorter. If we assume the lens to be 3-in. focus, the conjugates A and B being equal, will be 12-in. apart or 6-in. from the lens on each side.

In Fig. 4 we have caused the point of light A to be brought nearer to the lens than is shown in Fig. 3, let us say to 4-in. The conjugate B

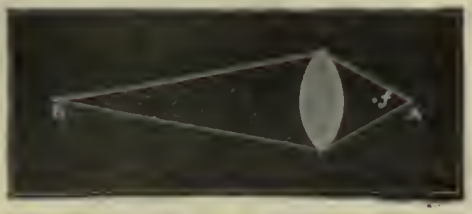

Fig. 4.

has moved further away from the lens—to 12-in. (4-in. and 12-in. being the conjugates of a 3-in. focus lens), and if we move the point of light A still nearer to *f*, say to 3½-in., the conjugate B will be found at 21-in. on the other side, and so on as A approaches the lens, B recedes, until at length, when the point of light arrived at *f*, parallel rays would be produced as shown in Fig. 1.

The Functions of a Lantern Condenser.

Now, let us see how these few remarks apply to a lantern condenser. One important function in a condenser is to collect as much light as possible, and in passing it through the slide, the rays now forming the picture must converge to a point somewhere in front, and that *somewhere* is in or about the centre of the objective in use—that is to say, the objective must be at B (Fig. 3), or at B (Fig. 4).

When a lantern and screen have been assigned to their respective places, there is only one position for the objective in use to make the picture focus on the screen, and as the conjugate B must meet in the objective, and, as has been shown, this conjugate has another conjugate A, which is the point of light, it is quite clear that the focus of the objective defines the position of the light.

If, then, the condenser be 3-in. focus and the objective 12-in. (or such as would require the conjugate B at 12-in.), then the point of light must be at 4-in. from the lens, as shown in Fig. 4; but if an objective of 6-in. focus be applied, the light must be moved back to 6-in., as shown in Fig. 3.

Now, the law that "diverging light varies in intensity inversely as the square of the distance," shows clearly that by moving the light back from 4-in. to 6-in. we have lost about one-half of it, and demonstrates the fact that whatever be the focus of a condenser best suited to a long-focus objective, it cannot possibly be near so good—as a light-collector—as a shorter-focus condenser would be when shorter-focus objectives are employed.

There is a limit to the shortness of focus for a lantern condenser, on account of the heat given off by the incandescent lime, and when this limit has been reached for use with a short-focus objective, the condenser must inevitably break if an objective of longer focus be employed.

Double Condensers.

Single lenses, such as are shown for simplicity in explanation at Figs. 1 to 4, are never used as lantern condensers for two good reasons, firstly, they would be too thick to stand the heat given off with the light; and, secondly, they suffer from a defect known as spherical aberration, of which we shall have something to say presently.

A biconvex lens of 3-in. focus and 4½-in. diameter would be about 2-in thick, and would not stand the heat for many minutes.

Now, let us see what two lenses will do.

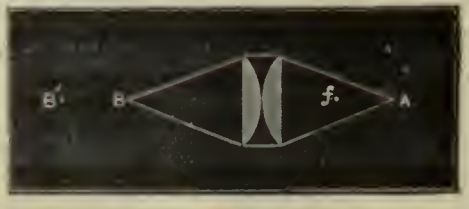

Fig. 5.

In Fig. 5 we have two plano-convex lenses, under similar conditions as explained in reference to Fig. 1; divergent light from a point A immerges practically parallel, and parallel light falling upon the second lens is conveyed to B; here we have very nearly the same conditions as at Fig. 3; but these two lenses, which are each 6-in. focus, are only half the thickness, consequently they are less liable to fracture by heat. If we place the point of light near to *f*, the rays immerging would diverge (see Fig. 2), and these diverging rays, falling upon the second lens, would converge to the conjugate B^1; but these lenses, being of equal diameters, the second lens would not take up all the diverging rays from the first lens, the marginal rays would be thrown into the mount, and therefore lost, as shown in Fig. 6.

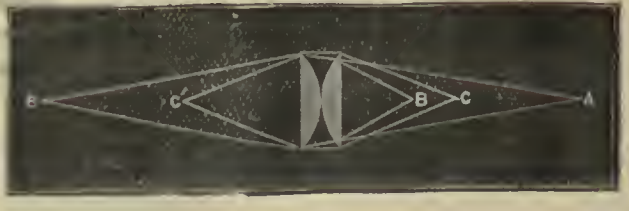

Fig. 6.

Where, for a pair of 6-in. focus plano-convex lenses, A B^1 represents

the conjugates of the second lens at 12-in. each; C C^1 the conjugates of the pair of lenses, viz., 6-in. on each side; B B^1 the 12-in. and 4-in. conjugates of the pair of lenses, and demonstrates the fact that of a 4-in. diameter front lens only 3½-in. of its diametar is utilised when the 12-in. objective is employed.

Triple Condensers.

If we introduce a third lens, which should be of long foci and consequently very thin, we should be able to get the light within the distance of say 2-in.; this would diverge the rays, and the middle lens would receive the diverging rays and pass them on practically parallel to the last lens, which would converge to the conjugate B^1, as shown at Fig. 7.

Fig. 7.

The advantage, then, is that we get a thin lens of suitable focus and diameter close up to the light, and with such a combination as shown at Fig. 7 light may be collected and utilised up to an angle of 95°, which is not possible with any single or double condenser.

Very early in this communication it was said that rays converged *approximately* to one point; for, as a matter of fact, no single lens having spherical surfaces has the power to converge rays *absolutely* to one point, so that it is not possible by any single lens to obtain an exact focus.

Sir John Herschel has shown that the spherical aberration may be reduced to one-fourth of that of a single lens in its very best form, by means of two plano-convex lenses having their convex surfaces towards each other, and their radii as 1 to 2·3.

But it was Dollond who, over one hundred years ago, first laid down the principle that spherical aberration of single lenses is proportional to the cube of half the angle of the transmitted rays. But, says Dollond, "if two glasses be so proportioned and situated that the refraction be equally divided, then they will each produce a refraction equal to half the required angle, and therefore the refraction, being in proportion to the cube of half the angle taken twice, will be but a fourth part of that which is in the proportion to the cube of the whole angle, because the cube of one is but the eighth part of the cube of two, and so the aberration where the two glasses are rightly proportioned is but the fourth of what must inevitably be when the whole is performed by only one lens."

Now, by the same reasoning, where the refraction is divided between three lenses, the aberration will be found to be but a ninth of what would be produced by a single lens, because three times the cube of one is but one-ninth of the cube of three.

To those who have followed what has now been said, the advantages of a triple condenser for lantern purposes must be manifest.

The condenser which we now introdnce to your notice is a triple combination, constructed on the lines here advanced, though the foci of the lenses mentioned to illustrate our remarks are not necessarily those we have adopted.

No reference had been made to the density or quality of glass, or to the various forms of condensers, and some other matters, with a desire not to make this communication too technical.

W. I. Chadwick.

LANTERN SLIDES BY REDUCTION.

[Holborn Camera Club.]

We are fast approaching a period when most of us will be looking back upon our summer's work; for the sunshine is leaving us, and the days are getting perceptibly shorter, and so we have to slacken speed, so to speak, giving us time to look back upon the path we have come.

We shall be turning out our negatives of '92, not with a view to printing, for this we have been doing for some time past. No! This time we have something else in our mind. We are thinking of lantern-slide making, and to that end we shall be reviewing them, good, bad, and indifferent.

We have looked them all over, and made our selection. Negatives brilliant and full of pluck, sharp and vigorous; one or two, perhaps, of the indifferent class—in other respects, perhaps, acknowledged failures; but we have selected them, for there is a small portion including, most likely (if the subject be landscape), distance and middle distance—or, in any case, a piece that is interesting, and from which we can get a good lantern slide by contact. We remember discovering this during their development, and how it had consoled us, to a certain extent, for our great disappointment at the general result. It was this that gave them their ticket for the fixing bath, and thus they were spared from the dust-heap and oblivion.

Why is the Reduction Method Neglected?

But, I would ask, how many are there who never made lantern slides but by this one method of contact in the printing frame, regardless of what there is in the negative besides the small piece which is taken to make a picture by itself? Why is it that so many amateurs who take up this most engrossing branch of photography never get any further than this stage? It cannot be that all their pictures require this very extensive trimming. I am not now referring so much to quarter-plate workers as to those who work in the larger sizes, for, obviously, the quarter-plate better lends itself to be used for the making of lantern slides by this means without, perhaps, serious loss of subject. Although even here, in many cases the compulsory cutting down of the picture is anything but an improvement, to say the least of it, especially if care has been taken in the selection of the subject and to get it properly on the plate. In such a case, to do the picture justice, a reduction must be made.

Why is it, I say, that this reduction is not more practised? Why should we not see your work on the white sheet without this mutilation? Let us see it as it is hung in the frames around your room?

The Apparatus Required.

I have not spoken disparagingly of the contact method, neither is it my intention to do so, for it is a very convenient and useful method, which does not require my demonstrating. I simply protest against its indiscriminate application. The excuse for this is generally, "Oh! it's such a trouble to reduce;" and the idea prevails with some that special apparatus is required. Now, it is my purpose this evening to prove that this is not the case, and I will endeavour to explain to you how lantern slides may be made by reduction from large negatives without any difficulty whatever, without any special apparatus beyond a deal board and two strips of wood. What I am about to describe to you now is no novelty, neither do I claim any originality for it; but it is a simple and, at the same time, practical arrangement. Assuming that your camera and lens are of half-plate size, and that the negatives to be reduced are of similar size, it will be best to have our board about nine inches wide, and for length three to four feet will be ample for all our requirements, the two strips of wood about the same length.

First of all, we set the camera up on one end of the board, then measuring the distance from board to centre of lens aperature, we mark same off upon a strip of wood or cardboard, which can be temporarily tacked on to the centre of the other, and so that it stands up vertically in front of camera. This done, we now take a printing frame, and having removed both back and springs, place in a spoiled negative, on which draw diagonal lines from corner to corner, so as to mark the centre; fasten this in with a drawing pin top and bottom. Now, we have to secure our frame on the end of the board with open side facing the camera, so that the centre corresponds with the mark on the piece of stick. There are two ways of doing this: either by placing a block of wood underneath, and screwing from beneath the board, or by screwing the frame between two upright pieces which can be secured to the edges of the board; either method will allow of hinges to be used, so that the frame can be shut down when out of use, but this is not essential to the efficiency of the apparatus.

Having done this, it will be well to test, by focussing in the camera, as to squareness and centering; this is best done by placing the apparatus, for that I will now call it, in a similar position to that which it will occupy when in use, viz., at a window, so that there is nothing to obstruct a clear view of the sky when looking through camera with negative removed. When found correct, take a lantern-cover glass, and, using it as a guide, mark off its dimensions on the centre of the focussing screen; now shift the camera up or down the board until a full view of the negative in frame is included in this space; then screw a strip of wood across the board at the back, and close up the camera; this will form a register, and keep it in position when the board is sloped (as it will most likely be, to get a clear view of the sky); similar strips or blocks should be fastened down either side to prevent shifting sideways. All that has to be done now is to secure the long strips of wood to the top of the frame—one at

each corner—so that the other ends rest on top of the camera at either side, and these can be joined by a strip across; then cover over with a focussing cloth, which can be secured by drawing-pins underneath, and now you have a serviceable reducing apparatus, and all you require is a lantern-plate carrier for your dark slides, which can be bought for a few pence, or a quarter-plate carrier, if you have one, can with very little ingenuity be adapted.

J. F. Stevens.

LANTERN SLIDES OF BEES.

Mr. R. A. H. Grimshaw writes as follows in the *British Bee Journal*:—

A few nights ago I had the privilege of spending an hour or two at a private *séance*—a dark *séance* it was, too, excepting as regards light reflected from the screen. To have the opportunity of seeing original photographs mounted as lantern slides and projected by the limelight lantern—photographs taken in Africa, America, and in almost every country in Europe, the whole of them from beginning to end being the handiwork of the exhibitors—was a rare treat indeed, and only to be equalled by the honour of having Mr. Cowan himself at the lantern, a work entailing more labour and fatigue than appears at first sight. Well, it was only one *more* proof of the love and self-sacrifice he has for bee-keeping and all that interests the bee-keeper.

To say that this exhibition of sun pictures from Nature herself was surpassed by a private view of the whole of the magnificent series of lantern slides on bees and bee-culture just issued by Messrs. Newton & Co., would be to say falsely; but speaking as a practical bee-keeper, who tries as much as possible to be *au courant* with the latest discoveries in the craft, I can fairly say that the whole fraternity are much indebted to the firm named for their enterprise and foresight in offering to the bee-keepers of the world such a magnificent *suite* of educational items. They are truly cosmopolitan and speak their tale through the eye, requiring no language of explanation to the apiarist, and very little I ween to even those who "do not know a bee from a bull's foot."

As artistic productions, real works of art, I must first speak of them. Mr. Freshwater, whatever else he is, is an artist, for he has succeeded in giving us *pictures* out of such prosaic materials as the appliances of a bee master. There is a balance and a grouping together, besides an acquaintance with chiaroscuro, telling of something beyond mere photography. The series of thirty-seven slides focus what appears to me a perfect educational code of bee-keeping. The wonder is, indeed, how we have managed winter evening lecturing so long without such necessary aids. One thing ought not to remain unsaid. The physiognomy of Mr. W. Broughton Carr seems destined to be handed down to posterity in these pictures, as the actual manipulator from whom the photographer has taken his subjects, the practical bee-operations depicted being direct photographs taken at Mr. Carr's apiary in Kent. In saying this, it will be taken for granted that in the bee-work pictured there is reliable evidence of the *workman*. I trust Messrs. Newton will see the advisability of advertising these beautiful slides for the benefit of lecturers.

GELATINE PLATES FOR LANTERN-SLIDE WORK.

[London and Provincial Photographic Association.]

In spite of the facility of manipulation and excellence of result claimed for collodio-bromide by many of its adherents, it does not require that one should be an accomplished prophet to predict that eighty per cent. of the slides made and shown at metropolitan and provincial societies during the coming lantern season will be on gelatine plates. For, while admitting that a lantern slide made on a collodio-bromide plate by an accomplished worker in this process is justly regarded among lanternists as the acme of perfection, yet when one comes to consider critically the slides occasionally shown at societies' meetings by average workers in collodio-bromide, and contrast them with the slides of the average worker in gelatine, it must, I think, be conceded that the advantage is with the latter. Again, there is a convenience and certainty about a gelatine plate that is rather absent from a collodio-bromide plate; the film is not so liable to abrasion in contact printing, nor anything like so prone to slide off the glass into the developing sink, as is the wicked wont of my collodion films when an especially fine slide is being developed. The development of a gelatine plate, also, is a process which the larger number of lantern-slide makers are sufficiently familiar with to prevent a feeling of strangeness when undertaking it. And, to sum up in favour of gelatine for lantern work, it would, I think, require rather an astute person to distinguish on the screen betweed a first-class gelatine slide and one on collodio-bromide.

When it comes to the home preparation of the plates, a point with which this paper has more particularly to deal, the advantage in simplicity of process and certainty of result is, in my experience, unquestionably on the side of gelatine. I have prepared many batches of collodion emulsion, some of them of very good quality, but could never depend on always attaining the same standard of excellence, and I believe my experience is also that of other workers. In gelatine emulsion making this uncertainty has never presented itself to me provided an approved formula has been adhered to, and the necessary manipulations carefully carried out.

The Preparation of the Plates.

The formula which has given me the most satisfactory result is, with slight modifications, due to Professor Burton, and was selected, after trying several others, because of the good range of colour that could be obtained with it. It is—

1.

Nelson's No. 1 gelatine	80 grains.
Ammonium bromide	210 ,,
Sodium chloride	50 ,,
Hydrochloric acid	5 minims.
Water (distilled)	8 ounces.

2.

Silver nitrate	400 grains.
Water (distilled)	2 ounces.

3.

Hard gelatine (Heinrich's)	400 grains.

Emulsification is performed with the No. 1 and No. 2 solutions, at a temperature of 130° Fahr., and after the silver solution has been added very slowly to the bromised gelatine during its vigorous agitation, the jar is set on one side for a short time, when No. 3 is added, having previously been thoroughly well soaked in distilled water. As soon as the last added gelatine is perfectly dissolved in the emulsion, the jar may be immersed in cold water, to set the contents quickly. It is necessary for success in lantern emulsions to work with solutions as cool as possible, and avoid any tendency to cook. The emulsion, if properly made, should show ruby by transmitted light, and will be in an extremely fine state of division.

After the emulsion has set quite firmly, it has to be washed, and this is accomplished by squeezing it through a piece of moderately coarse "scrim" into distilled water. Some emulsion workers have rather questioned the necessity for using distilled water in washing emulsion, and it may not be so desirable in ordinary negative emulsion, but a careful comparison between slides made from emulsions washed in tap and distilled waters leaves me in no doubt as to the advisability of using distilled water in every instance.

Having left the squeezed emulsion to soak for a short time in the vessel of distilled water, it is squeezed again through the canvas into a fresh lot of distilled water, and again left to soak for a short time. Half-a-dozen squeezes, and as many soakings between are, I find, sufficient to completely remove the bye-products from the small batch of emulsion that the above quantities will make. I consider there is more efficacy in repeatedly squeezing an emulsion than in the long washing so often advocated, and by adopting the above mode of washing it is possible, in a long evening, to make an emulsion, wash and filter it, and coat the plates. It is not necessrry to coat the plate thickly; indeed, rather the opposite is preferable.

Development and Variety of Tones.

With plates prepared in the manner just described, a good variety of tones is obtainable, from quite a warm chocolate to perfect black, and the clearness of the plate, if carefully made, is perfect. The developer with which warm tones are readiest obtained is made up from ten per cent. solutions of sulpho-pyrogallol, ammonium bromide, ammonium carbonate, and ammonium hydrate respectively. As an example I may give:—

Sulpho-pyrogallol	3 grains.
Ammonium bromide	3 ,,
,, carbonate	6 ,,
,, hydrate	3 minims.
Distilled water	2 ounces.

A great variety of tones may be got by varying the exposure and the quantities of the above ingredients.

The fixing bath is not an unimportant factor in procuring excellence in a lantern slide, for however clean the slide may be when it leaves the developer, if the fixing bath be even slightly discoloured, the purity of the slide is sure to be depreciated. The formula I use myself is :—

Chrome alum	1 part.
Potassium meta-bisulphite	5 parts.
Sodium thiosulphate	40 ,,
Water	160 ,,

This bath is an attractive green colour when made up, and retains its clearness until it commences to be saturated with silver, but it has always appeared to me unwise to continue using a fixing bath after it has commenced to show signs of saturation, and I strongly advise the use of two fixing baths in lantern-slide as in negative work. An acid bath before the final washing removes any suspicion of stain.

Intensification.

The intensification of lantern slides is a point deserving of more attention than I think it has hitherto received. With collodio-bromide it is a frequent practice to leave a fully exposed slide under-developed and gain the requisite density by silver intensification. Slides prepared in this manner are of the highest excellence. That gelatine slides have not been treated in the same manner is due, I feel sure, to the uncertainty of intensification. My first essays in this direction were with a modification of Mr. Wellington's sulphocyanide of silver intensifier, in which sulphohydroquinone and sodium carbonate replaced the pyrogallo and ammonium hydrate. The process of intensification was a very slow one, but the resulting slides were of high quality, perfectly clear in the high lights, and the original colour maintained unaltered. This intensifier was discarded, however, when it was found that an ordinary wet-plate formula gave equally good results in a more expeditious manner. The formula here given is one used for collodio-bromide plates and has answered perfectly in my hands for gelatine work :—

Silver nitrate	2 parts.
Citric acid	1 part.
Nitric acid	1 ,,
Water (distilled)	16 parts.

Two or three minims of this silver solution are added to a drachm of the ordinary ten per cent. solution of sulpho-pyrogallol, and the solution poured on and off the plate as in wet-plate redevelopment. When silver intensification fails with a gelatine plate, it is usually because of insufficient washing, and one reason for the success I have met with in the silver intensification of gelatine slides is due, perhaps, to the extreme thinness of the film, which favours the more perfect elimination of the fixing salt. Full exposure, moderate development, and silver intensification is the procedure I would suggest in making lantern slides.

In conclusion, I would like to assure intending emulsionists that they will find the preparation of a batch of emulsion, sufficient for a gross or two of lantern plates, a much simpler matter than the text-books make it appear, and the additional interest it gives slide-making is ample remuneration for surmounting the initial difficulties of the process.

George T. Harris.

STEREOSCOPIC SCREEN PICTURES.

Mr. John Anderton supplies the following further particulars of his invention for stereoscopic lantern projection :—

To obtain the effect of solidity, an ordinary biunial lantern is used, and a stereo transparency being divided, one picture is placed in the top, and the other in the bottom lantern. To obtain stereoscopic effect from the enlarged images projected upon the screen, one picture only must be permitted to reach the right eye, and the other the left eye of the observer, and to effect this purpose the inventor places before the lenses of each objective a polariser of simple construction. The image thus projected upon the screen appears to the unassisted eye to differ in no respect from an ordinary one; but, if it be looked at through a Nichol's prism or other analyser, the picture will be seen to appear and disappear as the analyser is revolved. If each polariser be placed in its lantern in the same position, the two pictures upon the screen appear and disappear at the same time; but, if they be placed at right angles to each other, one will be clear and distinct when the other has disappeared, and, if the analyser be turned through a quarter of a revolution, the latter appears and the former disappears. It is therefore obvious that, if each eye of the observer be supplied with an analyser, each fixed at a right angle to the other, one picture will fall upon the right eye, and the other upon the left, and, as the pictures are superposed upon the screen, no lens or prism is required.

Theoretically, light is lost by refraction, but, practically, it need not be considered, for, with a very moderate quantity of gases consumed, a well-illuminated picture, ten feet square, is obtained. A special screen is used, having a surface that will not destroy the polarisation of the pictures, and the polariser is so constructed that the definition does not suffer to any appreciable extent. The little analysers, or eyeglasses, take a form similar to that of a very small opera-glass, the tubes of which they are formed being one inch in length and one inch in diameter, and the total weight is under two ounces. Each pair has a convenient handle attached, so that they can be held for any length of time without occasioning the slightest inconvenience or fatigue.

The effect of the partial superposition of two dissimilar pictures is, of course, to give a picture blurred with double outlines; but the instant the little glasses are raised to the eyes the picture becomes a well-defined and perfectly stereoscopic one. Special slides are not required. Any negative taken by a stereoscopic camera that is sufficiently sharp to bear the necessary enlargment can have lantern slides made from it, and these can be coloured if desired.

The lanterns are exceedingly simple to use, for, having been turned on, they need no further attention. The operator has, therefore, nothing more to do than change his slides and approximately superpose them. In one instant the polarisers can be withdrawn, and the lanterns used for all the other purposes for which a biunial is required, and, upon the other hand, the polarisers can be instantly placed in position for stereoscopic effects. Messrs. R. Field & Co., 142, Suffolk-street, Birmingham, are the sole makers.

OVERHEATING IN DOUBLE LANTERNS.

In a double lantern where one is placed above the other, as in American lanterns, the difficulty has been to so arrange the ventilation as to prevent the overheating of the upper lantern and yet have it very compact, and comparatively light-tight.

Mr. Charles Beseler, of New York, has devised a simple yet ingenious way of protecting the heat outlets arranged around the top and sides of the casing, by peculiar shaped angle plates, so formed as to direct the escaping heat and reflected light rearward. Any extraneous light is thus prevented from striking the ceiling, the screen, or emerging from the side to the annoyance of the operator. A sheet of asbestos felting is placed between the two lanterns, but does not affect the easy ventilation of the lower one. The light-tight casing is movable on the rods, and, when the lantern is set up, is drawn back, which exposes the condenser and places it outside of the casing, thereby preventing it from sweating or becoming overheated. There are simple but convenient adjustments of the lime carrier, and jets and extra flange rings are provided for the quick replacing of lenses of different foci, according to the size of picture desired. A bellows in front of the slide-carrier prevents the escape of light.

THE LANTERN CRAZE IN PHOTOGRAPHIC SOCIETIES.

To our mind it is decidedly a step in the downward direction when so many of our photographic societies become imbued with the ruling desire to convert everything into a lantern exhibition.

For illustrative purposes, says *Anthony's Bulletin*, especially when used in connexion with a lecture, the lantern has no superior, or even equal. To outsiders and the general public a lantern exhibition has many attractions, and, when used to excite a healthy interest in the doings of a photographic society, it is undoubtedly of much benefit. To such an employment of it we would offer not the slightest objection or criticism. But, alas! few are the cases where the task once acquired remains limited within reasonable bounds.

No other phase of the photographic mania seems to take such absolute possession of its devotees. Once a lantern-slide fiend and everything else is dropped—prints, negatives, everything is judged by the sole standard of "Will it make a good slide?" If so, it is enthusiastically received, and permission is at once craved to copy it. If unsuitable, by reason of some particular quality, which a hundred chances to one is that which makes it especially valuable in your eyes, it is cast aside with a superficial glance, and the lantern fiend goes on with his never-ending search for something to make a slide from. Books, illustrated articles, a few insignificant $3\frac{1}{4} \times 4\frac{1}{4}$ bits out of large negatives—nothing, in fact, is secure from his ravages. And to what end?

Without doubt, this persistency has resulted in a great improvement and perfection of plates, and developers for transparencies, and, so far as it goes, has in this way been of benefit to the fraternity at large.

But it is claimed that slides are far more permanent than the much-abused and evanescent silver print. Try a platinum, or bromide, or carbon, or a hundred other prints, and compare their permanency with your boasted slides. Moreover, let a few of those self-same slides fall on the floor, or come in contact with the vigorous dusting of a lately imported and quarantined domestic. If one out of a dozen survives, you are fortunate indeed.

Moreover, at its best, a development of this kind is a mechanical one, pure and simple—a mere reproductive process, beautiful in many instances, it is true, but neither more nor less than this.

Far different is it to the tentative and careful development of some cherished exposure which you have waited weeks to obtain, and exercised all your skill to have perfect in every detail. Eagerly you watch it come up, faintly at first, then gathering strength and detail. Has the lighting been as good as you wished for? Has the wished-for prominence of a certain object been destroyed by an unsuitable background? By some happy chance did you catch that fleecy cloud bank in the east, and can you keep from losing it in the density of your sky? A hundred questions rise, and with them your hopes. At last it is developed, and you have your perfect negative. Such a beauty! Surely it was worth trying and waiting for, and the skill and experience that you have gained as the years have gone by are something to be proud of—to glory in.

You hasten to contribute a print of it to the Club Album, and perhaps at some future day you have the pleasure of seeing some obscure little corner of it possessed of certain peculiar qualities, thrown upon the screen; and a feeling of longing for the rest of it, and indignation at the man who thus ruthlessly dissected your masterpiece, arises in your breast.

Not satisfied with this mild species of "rubbing it in," you find that the intelligent operator has hopelessly sandwiched it in between a tenement-house scene and the Seventh Regiment marching down Fifth Avenue.

And just here we have another grumble to make, the heterogeneous jumbling together of any number of dissimilar subjects that usually characterises a so-called lantern exhibition.

If any of us had the good fortune to possess a slide of that ancient relic Noah's Ark, it would undoubtedly be placed between "Our President Coming Around the Corner" and that well-known diminutive Negro study of "Who's a Democrat?" followed by the inevitable *chef-d'œuvre* of the evening—an impossible rendering of the two Huguenot lovers, or plain American "Spoons," as our country cousins would term them, were it not for their title.

To return, however, work of this kind is unworthy the serious attention of our societies.

Why not institute competitive researches as well as competitive print exhibitions. Let certain subjects worthy of investigation and discussion be proposed, and the members invited to compete in an investigation of them.

Surely a medal for marked progress in photographic science, not mechanical skill, would be of far more value to the owner, and be far more to his credit than a prize for the best composition of nobody's choice or somebody's impossible offer.

Of course all of us have our hobbies. Some prefer the picture side of photography, some the general investigating side, and some the strictly chemical aspect of our art.

To each we would say, Do some good systematic work, which, when done, would be of value to our fellow club-members, and not serve solely as an ornament to our albums.

Do not crowd out the beautiful—there are enough hard, stern realities in life; but do crowd out that desultory fashion of making exposures at random and because it looked rather pretty on the finder.

If you are interested in faces and types, don't display it by innumerable groups, most of them badly composed, and remarkable chiefly for their stiffness.

Take down your hand camera and frequent the highways and byways of the city. Make your exposures on subjects possessed of action, illustrating some particular trait or characteristic.

The Italian sorting the rubbish on the city dumps; taking his noonday meal; disturbing the contents of an ash barrel, or sporting the gorgeous uniform of the street-cleaning department in a successful effort not to keep the street clean.

Follow him in his various moods and occupations; study the women carrying heavy burdens on their heads, and walking with that peculiar gait so characteristic of them as a race.

Record them in their holiday attire; visit the "Bend" and the Italian quarters, and jot down a photographic impression of a motley crowd.

Note the children from their early appearance in tight bandages, which completely envelop them, through their gradual development as street gamins, boot-blacks, and fruit vendors, and you will have a set of pictures valuable and interesting, recording manners and customs in the only satisfactory way known to modern science.

Through their art we have learned the customs of many a bygone people, and our own some day will be recorded in a similar manner.

Extend your investigations through the various nationalities, classing each nation by itself, and you will find an added interest to your work, and a field that is almost limitless.

Do you want something more scientific? Try upon a certain brand of plates the effect that different colours have; place them side by side and in contrast, making equal exposures, and you will have learned much as to what not to try. Do this systematically, and then compare it with results obtained in the same way from the same subjects, but with the interposition of various colour screens.

Do you know exactly the difference in effect that your different stops give? Mathematically you know the difference in exposure, but have you ever tried the same length of exposure on a given subject, with a given light, substituting successively one stop for another till you have used them all? Try it once, and carefully compare the results. Then try the same subject with each stop, giving it the proper exposure; each time vary your subject, and by the time you have finished you will have learned more of stops and their effect than you ever dreamt of before.

Test your developers in a similar way. Vary their proportions, and try them on equal-length exposures of the same object. Keep your negatives and label them, and you will find few people to whom they are not of interest.

This is what we mean by systematic work. Work that has some object in it, and which, when performed, is something more than pretty. You have learned by it; your friends can also benefit by seeing your results in a way that volumes could not bring home to them.

Photography is worthy of being something more than a plaything; our clubs of being something else than print and slide collections, often of doubtful merit, and always without definite aim or object. Photography doesn't need such encouragement. It has got far beyond that. But it does need honest, painstaking, and, above all, systematic work, to keep it from degenerating into a mere plaything.

HIRING LANTERNS FROM PHOTOGRAPHIC SOCIETIES.

According to the Club and Dark-room bye-laws of the Bury Photographic and Arts Club, which we have just received, members of the Lantern Committee who may desire to hire the Society's lantern can do so, the charge for the lantern, ten-feet screen, cylinder, &c., and one lime, being 2*s.* for one night, and 1*s.* for each of the two following nights used; extra limes will be charged for. If it is desired to use oil with the lamps, the charge shall be 1*s.* 6*d.* for the first night used, and half-price the two following nights. Charge for the use of cylinder or screen 6*d.* each per night. No member shall have the use of the lantern, &c., for more than two successive nights, except on the written permission of the Secretary.

The following is the list of apparatus of the Club for hire:—Single lantern, complete with condenser, lens, carrier, blow-through jet, india-rubber tubing, &c. Four-wick oil lamp for the above. Ten-feet oxygen cylinder with coupling and key. Duplex oxygen regulator. Changing tent. Two magnesium wire reflectors. Ten-feet square screen with frame, in bag. Twenty-feet square screen with frame.

It appears to us that the example here set by the Bury Society might profitably be taken advantage of by other societies, who would thus have an opportunity—which is often much needed—for extending their sphere of usefulness.

LANTERN FIXTURES.

Lantern Nights at the Photographic Exhibition.

During the course of the Exhibition there will be displays by means of the Optical Lantern, every Monday, Wednesday, and Saturday evening, as below:—Monday, October 10, slides by Mr. W. England; Wednesday, October 12, by Mr. T. M. Brownrigg; Saturday, October 15, by Mr. H. Little; Monday, October 17, by Members of the Photographic Club; Wednesday, October 19, by Members of the Manchester Photographic Society; Saturday, October 22, by Members of the Newcastle Photographic Society; Monday, October 24, by Mr. A. R. Dresser, from photo-

graphs at the "Wild West Show;" Wednesday, October 26, by Members of the Convention; Saturday, October 29, by Members of the Birmingham Photographic Society; Monday, October 31, by Mr. E. G. Lee; Wednesday, November 2, Mr. E. G. Lee, Amateur Photographers' Field Club; Saturday, November 5, by Mr. Richard Keene; Monday, November 7, to be announced later on; Wednesday, November 9, by Mr. B. G. Wilkinson.

The management of the Photographic Society's lantern is as usual in the experienced hands of Mr. R. R. Beard.

Correspondence.

THE DANGERS OF OXYGEN-MAKING.

To the Editor.

Sir,—Seeing your notice that you will devote a special supplement to the Lantern and its working, perhaps my experience may be interesting to your readers, and may serve as a warning to all who make their own oxygen gas. Experience, I regret to say, that has left me broken down in health and spirit, and with marks that I shall take to the grave, all through a chemist's blunder. Being asked to illuminate some Tableaux Vivants by the aid of the Lantern, I sent to a photographic firm of chemists for six pounds of oxygen mixture, viz., four parts chlorate potash, two parts black oxide of manganese. The parcel came by parcel post, labelled oxygen mixture. I weighed out one and three-quarter pounds of the mixture, put it into the retort (a safety one), placed the retort on a small fire in my studio, and in less than one minute a fearful explosion occurred. The roof and side of my studio were blown to pieces, skin and flesh were burned off my left hand from the finger tips to the elbow; my right also. My face and throat were one mass of cuts, and my eyes were so terribly injured that the doctor thought I would be blind for life. The retort was made bits of, and twisted in all shapes. The bars of the fire grate were blown in all directions, and some entered in the cement wall opposite (eleven feet) to the depth of half-an-inch. The report was heard at a great distance. How I escaped Providence alone knows. I think I must have been in a stooping position, otherwise very likely I would not be alive to pen this letter.

After the explosion, blind and bleeding as I was, I made for one of the doors (there were two), and I succeeded in gaining the open air. A few seconds more and I am sure I should have been suffocated. The feeling was something fearful. The fumes given off were like so many sharp knives cutting the throat inside. I was quite exhausted the moment I reached the door, and fell.

I shall not dwell on my sufferings for the past three months; but to give you an idea, I was eleven stone weight, and when weighed by a high medical authority, to whom I went to consult about my health four weeks after the explosion, I only weighed eight stone eleven pounds. I had to undergo two operations for my eyes, and my right eye, I greatly fear, will never be the same again.

After the explosion I got the mixture analysed. I have four and a quarter pounds of it still. And what do you think this photographic firm of chemists sent me to make oxygen gas from? They sent me a mixture of chlorate of potash and *sulphide of antimony*, not a trace of manganese.

I do not mention the name of the firm as I am bringing an action against them, and my only reason for writing these particulars is that you may warn your readers to be careful if they make their own oxygen gas to get the proper mixture, and not get a *powerful explosive*, as in my case, which has left marks on me that I shall take to the grave.

Any further particulars I can give you you are welcome to.

Should you wish to inquire about the explosion, the police here can give you all information, as they were on the scene ten minutes after the occurrence, and, I believe, made a note of everything, and also the condition I was in.

Sincerely hoping that this letter may be the means of preventing similar accidents, and a warning to all.—I am, yours truly,

Thos. B. Walshe.

P.S.—I have all the pieces of the retort, bars of grate, &c., and shall be glad to send you a photograph of them should you wish it.

Rosscarbery, co. Cork, Ireland. Oct. 1, 1892.

[We should be pleased to see the photograph.—Ed.]

REFLECTORS—GASOLINE.

To the Editor.

Sir,—I shall be glad if you will tell me about the use of reflectors to throw the light from the lime when used *with its back* to the condensers and placed in the focus of the mirror. This is, of course, an unusual method, but has, I fancy, some advantages over the usual method. Further, I would ask for account of experiences with gasoline in an ordinary saturator.—I am, yours, &c., Haslemere.

September 26, 1892.

Lantern Notes and Queries.

C. R. B. (York).—The size of American lantern slides is $4 \times 3\frac{1}{4}$.

Simpleton.—You have not been misled. A whitewashed wall answers admirably as a screen.

"Supplement."—We shall doubtless have an article on the subject in the November supplement.

A. J.—Yes; amidol answers excellently for lantern slides. We have seen some charming slides developed with it.

V. E. Moore.—No; few people make their own oxygen nowadays. See a letter on the subject in another column.

Inventor.—Send us a description and drawing of the lantern, and we shall then be the better able to judge of its "novelty."

S. Peel.—Mr. Chadwick states the advantages of triple condensers in the course of his paper in another part of the Supplement.

F. Potter asks for the names of makers of "adjustable lantern stands."—Any lantern-dealer would be able to supply you with what you require.

Disc.—The length of the hall being twenty-five feet, you would require an objective of six inches focus in order to produce a disc of twelve feet in diameter.

Inquirer.—Messrs. Archer have one of their lanterns in the present exhibition of the Photographic Society at Pall Mall. By paying a visit to the Exhibition you would be able to examine it at your leisure.

B. Olivea.—The whiter the screen the better. If it is so discoloured as to degrade the lights of the picture, you had better have it repainted. Messrs. J. Avery & Co., of Great Portland-street, will undertake the matter.

Screen.—You are in error. Lantern slides on celluloid films may take the place of glass slides. Of course some sort of special carrier is necessary, and such a one is, we believe, to be obtained of Mr. J. D. England.

Mr. Alfred Underhill, of 32, Clarendon-road, West Croydon, has sent us his supplementary list of lantern slides for 1892-93. It includes many new series, and gives particulars of the various departments of Mr. Underhill's business, which embraces designing and drawing, slide colouring, &c.

To test a lantern objective for flatness of covering power, Mr. G. C. Norton employs a square of muslin netting mounted between two plates of glass three and a quarter inches square. This answers better than a photographic transparency in which there is often a falling off in definition towards the edges.

For the purpose of making tracings on glass of photographs to serve for lantern illustrations, Mr. Thomas Haddow, of Maitland-street, Edinburgh, has sent us a sample of an opaque black ink which flows freely from the pen. For extempore purposes during lectures this possesses certain advantages over writing ink, especially as regards opacity.

At a recent meeting of the Port Elizabeth Photographic Society, he development of a plate was shown on the screen by means of the lantern, and aroused very great interest among those present. This was stated to be the first occasion on which such an experiment was conducted in the town.

Catalogues Received.—Messrs. G. W. Wilson & Co., Aberdeen. This gives particulars of several additions to Messrs. Wilson's well-known series of slides.—Messrs. F. York & Son, 67, Lancaster-road, Notting Hill, W. In this supplementary list Messrs. York also include many novelties.

MONTHLY SUPPLEMENT

TO THE "BRITISH JOURNAL OF PHOTOGRAPHY."] [*November* 4, 1892

THE LANTERN RECORD.

CONTENTS.

SOME DISADVANTAGES OF COMPRESSED HYDROGEN.

In most of the circumstances under which lantern entertainments are given a supply of house gas is usually available, and thus the provision of compressed hydrogen is unnecessary. Occasion, of course, often arises when a domestic source does not exist, so that recourse must be had to the assistance of the compresser. For this purpose both pure hydrogen and the carburretted variety are at command.

The advantages of pure hydrogen over the commoner form of gas are not on the whole of a very marked nature as regards the quality of the illumination given, which combined with the additional expense have sufficed to restrict its uses to a limited degree. Its purity, however, relieves it from one of the drawbacks of the ordinary gas, to which we are now about to advert, so that it is undoubtedly more reliable and agreeable to work.

Pure hydrogen, again, so far as we can ascertain, undergoes no chemical alteration, even though it be suffered to remain in the cylinder for an abnormal period. As much, however, according to the opinion of several experienced lanternists with whom we have been in communication on the subject, cannot be said of the ordinary hydrogen gas. The use of this within a reasonable period after the cylinder has left the compressers, say a few weeks, entails no convenience; but, if a period of months through unavoidable causes be allowed to elapse before the gas is required, the most unpleasant effects result in the working of the lantern.

An incrustation collects at the extremity of the hydrogen tube, which again is projected in the shape of dark flaky fragments upon the lime, thus reducing the light to a condition of low illuminating power and intermittent constancy, which is not restored to its normal degree of brightness until the gases are turned off and the offending fragments removed from the tube and the lime. Under such circumstances as these, it can well be imagined that an audience would be rather incommoded, and the operator chagrined, at the momentary failure.

The cause of this has been ascribed to some species of chemical reaction taking place between the hydrogen and the cylinder after a certain length of time, whereby minute fragments of oxidised metal are held in suspension in the gas, and subsequently converted into appreciable atoms, with the result described. How far this is correct we are unable to say. Perhaps those familiar with the compression of hydrogen can throw some light on the matter. Pending such an elucidation, however, the obvious course for the lanternist to take is to, where possible, use freshly compressed hydrogen in preference to that which may have been in the cylinder for, say, months.

LANTERN NOTES AND NEWS.

DURING the Stanley Show of Cycles, &c., which is to be held at the Agricultural Hall from November 18 to 26, there will be photo-cycle lantern entertainments, including the following subjects:—"The Evolution of the Cycle," with illustrations of all types of machines, from the Dandy Horse to the present-day Cycle; "From Ditton to Ripley in Thirty Minutes;" "The Great North Road," from London to York; "Cycling Celebrities;" "Our Cycling, Camps;" "The Path;" "Celebrated Starts and Finishes." The Hon. Lecturer will be Mr. George Lacy Hillier, of the Stanley Cycling Club.

* * * * *

AT the meeting of the Lantern Society on October 24, Commander Gladstone, the Hon. Secretary, showed a lantern of his own design, which, from the description given, appears to have many points of novelty about it. In its construction aluminium was used wherever practicable, and, instead of the metal-lined mahogany body, there was a cloth curtain lined with asbestos; the condenser mounted in aluminium was held between two thin plates of the same metal, and the slide carrier was held rigidly in position by means of an aluminium plate and two screws. The lens was mounted in a plain aluminium tube, and was carried by a small saddle, moving along the front board by means of a rack and pinion, and connected to the lantern body by a small camera bellows. For packing away, the whole thing folded up, and together with all the necessary fittings and two regulators stowed away in a box $18 \times 12 \times 5\frac{1}{2}$ in. The total weight, including the box and regulators, was about twenty-one pounds, the corresponding weight of the lantern which it has superseded being thirty-eight pounds. The space for the jet was practically the same as in an ordinary lantern, so that any jet, or an oil lamp, could be used with it.

* * * * *

THE Lantern Evenings of the Photographic Society of Great Britain have been, we gather, very popular this year. On the occasion when the slides contributed by the Photographic Club were exhibited we were pleased to notice a large and interested audience, who appeared to be highly delighted at the remarkably good qualities of the Club's slides, as well as with the terse humour of Mr. F. A. Bridge, who "described" them. Whatever else its critics may find fault with, the management of the lantern at the Society's meetings is difficult to excel.

* * * * *

BY the way, we may take this opportunity of reminding our readers that the Lantern Entertainment at the Photographic Society's Exhibition, in aid of the Photographers' Benevolent Association, takes place (by permission of the Council), at the Gallery, Pall Mall, on Friday evening, November 4th. Tickets, price sixpence each,

may be obtained of Mr. Snowden Ward, the Hon. Secretary, Memorial Buildings, E.C., or of any member of the Committee of the Benevolent Association.

* * * * *

For the evening in question a large number of tickets have already been issued, and doubtless sold, *apropos* of which a friend (and one, moreover, who, to our knowledge, has been a supporter of the Association for many years) has suggested that the benefit might in future be so arranged as to extend over three or four evenings instead of only one. The reason for this is that many hundreds of tickets are apparently being issued for one evening, and the room at Pall Mall has not anything like the accommodation necessary in case a large percentage of ticket-holders should put in an appearance.

* * * * *

Mr. F. P. Cembrano, whose ability as an exponent of architectural photography is a matter of common recognition, laid stress the other evening, when speaking on the subject before the Photographic Society, on the value of the optical lantern for giving enlarged pictures of architectural subjects. Further, he dwelt upon the advantage of a large screen over a small one for showing off the slides to better advantage. We do not know whether the lantern is in requisition for this purpose by the professors of architecture at the various colleges and universities; but it can easily be seen how useful it would be in the lecture theatre, especially for acquainting the student with delicate details of architectural style on a convenient scale, which, as a rule, are only to be studied in comparatively minute drawings.

* * * * *

The lantern was put to a somewhat novel use at the last meeting of the London and Provincial Association. A theory of Robert Hunt that red light overpowers or rather neutralises to some extent the actinic influence of white light on a sensitive surface having been recently quoted, it was suggested that the matter might very easily be put to experimental proof by means of the lantern. Accordingly, at the meeting in question, the experiment was tried in the following manner:—From the upper chamber of the biunial lantern three kinds of red light were projected on to a sensitive plate, affixed to a blackboard, the white light, much stopped down, emanating from the lower lantern. Three exposures were made, and the net results of the experiment went to negative the assumption that red light, such as is used for dark-room illumination, had any neutralising effect on the white light.

* * * * *

A practical class on *Lantern Slides and Lantern Work* (by the dry-plate, wet-collodion, and collodion-emulsion processes) will be conducted by Mr. Charles W. Gamble, at the Polytechnic Institute, 309, Regent-street, on Wednesday evenings, commencing November 16, at eight p.m. This class includes copying illustrations from books, enlarging and reducing negatives, the use of the optical lantern, and all manipulative work connected with the lantern.

* * * * *

A beautiful and instructive lecture experiment, illustrative of the conditions of the heated atmosphere which give rise to the mirage, is described by MM. J. Macé de Lépinay and A. Perot, in their "Etude du Mirage," which appears in the *Annales de Chimie et de Physique*. Water is poured into a long rectangular trough with glass sides, and covered with a layer of alcohol about 2 cm. thick, containing a trace of fluorescence. After a few hours, during which the alcohol diffuses slowly through the water, a flat beam of light is sent through the mixture at a very slight inclination to the horizon. Under these conditions a kind of garland of light is seen to traverse the liquid, due to a series of curvilinear deflections or "mirages" in the less highly refractive water below and total reflections at the upper surface of the alcohol.

A NOTE ON COLOURING LANTERN SLIDES.

The long winter evenings offer many opportunities for making lantern slides, when there is little else to photographically occupy the time, unless, it may be, printing and enlarging by artificial light in its various phases. But, to the greater number of amateurs, large work does not offer the attractions that work which can be performed in a limited space generally does. The ruling household powers, more often than not, look with anything but favour on the so-called "slopping about and making messes" entailed by working either large plates or paper. Consequently, lantern work (the "mess" being reduced to a minimum) is better tolerated.

There is, however, somewhat of monotony in plain slides, that may be occasionally varied with advantage. I allude to colouring. *Imprimis*, a badly coloured slide is, perhaps, one of the most offensive kinds of pictures that can be made; the large scale on which it is shown emphasises its shortcomings, and it has, without doubt, a commonplace, vulgar effect. Most persons unacquainted with the process of slide painting imagine that to do so *well* requires very considerable artistic ability and mastery over the material, even when the ordinary transparent colours are used. A certain amount of skill is required that may be too much for those not accustomed to water-colour painting. In the alternative method I now propose, such a very small modicum of painting ability is required that most of those who can take a photograph would be, with a little practice, equal to it, and obtain results that, considering the little trouble required, are decidedly satisfactory.

Procure an assortment of Judson's liquid dyes of suitable tints, a small quantity of spirits of wine, not methylated, and some camel-hair pencils, small paper stumps, and a piece of glass to do duty as a desk. I may here say it is of no use trying to mix the dyes like other colour in order to make certain tints, for one colour seems to destroy the other instead of forming a tint midway between the two. The dyes must therefore be used alone, diluted more or less with spirits of wine, and one tint allowed to dry before another is applied. The principal difficulty is in avoiding the thickening of colour at the edges of the stroke, but with a little practice this is easily overcome. Begin with the most delicate tints first, in a landscape the sky and water, finishing with the more pronounced colours. A drop or two of a suitably coloured dye being put into a small saucer, add sufficient spirit to dilute it to the proper tint, having at hand a little plain spirit into which the brush can be dipped as occasion may require; owing to the volatile nature of the medium, promptitude must be used to avoid waste, or the different tints may be kept diluted in small bottles.

Supposing we desire to tint a moonlight scene with good clouds, and bright reflections on the water; a cottage with the windows illuminated; or lanterns hanging to the rigging of ships. Firstly: take a small stump, dip it into a solution of wax in benzole, or suitable greasy matter, going over all parts carefully that have to remain colourless. The windows and lanterns having been tinted yellow or red, let these be waxed also; the slide then may be bodily immersed in weak greenish blue dye; blot off the edges, and dry. This will be probably all that is required to complete the picture. With a daylight view, tint the sky pale blue, softening off the colour towards the horizon with plain spirit, then carefully go over the landscape with suitable tints, always putting on the lightest and most delicate first, and drying before the application of the darker greens, &c. It is best to use but little colour, slightly tinted pictures having the best effect on the screen. Simple as this process is, excellent results may be obtained with little practice. Some colours are apt to dry duller than others. When this is the case a little gelatine solution poured over will restore the brilliance, care being taken to avoid dust in drying.

E. Dunmore.

LANTERN MEMS.

Lanternists will do well to remember that hydrogen cylinders must now have left-handed threads to the valves in order to be filled by the gas-compressing companies, and those who have not already had the change made will do well to have it done at once. Also their regulators for hydrogen to be made left-handed instead of right-handed as formerly.

* * * * * *

Cylinders containing hydrogen that has been laying by since last season should be tested, as the gas is liable to be impure, and, if so, will clog the jet in use, a chemical action taking place from the impurities of the carburetted hydrogen acting on the steel of cylinder. The best way is to fix tubing to jet and light up, putting on a lime as usual.

* * * * * *

The limes after a little use appear quite red or discoloured when impure hydrogen is used, and when this is so it is better to let the gas escape in the air, and send the cylinder up to be cleansed and refilled, a special mention being made of the fact when forwarding the cylinder to the optician.

* * * * * *

The samples of compressed hydrogen I have had occasion to use and

see tested during the last six months, have been of much purer quality than it used to be, and seems quite equal to being kept six months or so.

* * * * * *

Triple condensers are being taken up generally by the trade, and no doubt will be found useful for many purposes of projection. One form at least is made to separate so that the back lens can be removed, and a long-focus condenser is then available for long-focus lenses.

* * * * * *

Whether double or triple, the condenser must be of such a focus as will be suitable for the objective employed, and in practice one that is perfect for very short-focus front lenses, say of four and a half or five inches focus, or for microscope projection, will not be suitable for long-focus objectives of ten, twelve, or fourteen inches focus without separation or modification of the combination.

* * * * * *

Protecting glasses for condensers have been applied for years past in order to save the back lens from getting broken when the light has to be very near the same to get the correct focus; but, if I have read correctly an advertisement that appeared lately, a patent has been applied for for this application of a protecting glass to a condenser. Should it be so, it stands to reason that the patent cannot be valid.

* * * * * *

"Cut-off" dissolvers, "cut-offs" to jets, and screw-down valve taps to jets, are becoming popular, and seem to be appreciated. There is no doubt about the convenience of the former and its economy, while the latter are invaluable for regulating the supply of gas with the new high-pressure mixing jets, and, if fitted in the plug of the stop-cocks with lever handles as well, they answer a double purpose, viz., for fine regulation, and as a "cut-off."

* * * * *

In using mixed-gas jets, the bye-pass tap on oxygen side of dissolver must always be turned off. Popping at jet is sometimes caused by this being turned on, accidentally or otherwise.

* * * * *

Mechanical figures, cut out of metal and articulated, will shortly be placed on the market. I saw recently some very cleverly made and arranged samples, in which subjects representing Gladstone chopping a tree, Gladstone and Salisbury wrestling, Ally Sloper rising from behind a table, bowing, and opening and closing the mouth as if speaking. The movements were so natural that one could almost suppose the muscles of the arms and legs of the wrestlers actually moved, and, with the wood-chopper, the axe not only rises and falls, but the body moves forward and up and down. Being opaque, the figures will be projected on the screen as silhouettes.

* * * * *

Leaky joints, from indiarubber getting loose or perished, are far more frequent than some suppose. It is wise every now and then to cut an inch or so off the end where it has *set* to the stretched size, and so get a new portion of the rubber for the connexion. With compressed gas, the tubes should be fastened on with string, wire, or, better still, a "grip" clip.

* * * * *

From striking an average, I find that for a two hours' entertainment with a biunial lantern, the amount of gas used when employing best mixed-gas jets is seven feet of hydrogen and six feet of oxygen.

* * * * *

The old idea of the blow-through jet being the only "safety" one is gradually getting exploded, for, with the gases compressed in separate cylinders (and fitted with automatic regulators) the better kinds of mixed-gas jets can not only be used with perfect safety, but with greater convenience, and will give fifty per cent. more light. This form of limelight is adaptable for use in a very small space, and is, of course, quite independent of any gas-fittings, which is in itself a great saving of time when in a strange place.

G. R. Baker.

SOME NEW FEATURES IN CONNEXION WITH LIMELIGHT LECTURING.

The brilliant success which attended the course of lectures given in connexion with the Glasgow Photographic Exhibition held last year had, doubtless, much to do in the way of inciting the Council of the Fine Art Institute in Glasgow to lead off again this season with a five weeks' course of lectures given nightly, commencing September 1 and ending October 8.

This course embraced thirty-three lectures, and, with the exception of four, all the engagements were filled by amateurs, many of whom must have gone to considerable expense and trouble in getting up their lectures on new subjects especially for this occasion; and it must have been highly gratifying, not only to the Council of the Institute, but also to the Glasgow public, to find that, with one single exception (where the lecturer was confined to his bed through illness), the original programme was carried out almost in its entirety.

It is interesting to notice some of the features of this undertaking, and which, doubtless, helped in no small degree to bring about the success which attended it.

First and foremost must be noticed the very attractive programme which the Council offered to the public. It was as follows:—

Sept. 1st, Thurs.—"The Waterways of Holland." Mr. George E. Thompson.
2nd, Fri.—"The Volcanic Eifel and the Moselle." Mr. George E. Thompson.
3rd, Sat.—"Rambles along the Riviera." Mr. George E. Thompson.
5th, Mon.—"The South End of Arran, from Brodick Bay to Benan Head." Mr. William Lang, jun, F.C.S.
6th, Tues.—"Hogarthian Humour." Bailie John Ure Primrose.
7th, Wed.—"My Trip to India, *viâ* Suez." Major F. W. Allen.
8th, Thurs.—"Trip to London and Brighton." Mr. T. N. Armstrong.
9th, Fri.—"Greenland's Icy Mountains." Mr. John W. M'Call.
10th, Sat.—"Ireland and the Irish." Mr. John W. M'Call.
12th, Mon.—"Some Characteristics of Scottish Scenery." Professor John Young, M.D.
13th, Tues.—"Sir Walter's Land" (*with song accompaniment*). Mr. George G. Napier.
14th, Wed.—"Italian Highways and Byways." Mr. Frederick Clibborn.
15th, Thurs.—"Normandy." Mr. Frederick Clibborn.
16th, Fri.—"Among the Austrian Alps and the Carpathian Hills." Pastor Geyer.
17th, Sat.—"Glasgow in Ye Olden Time." Rev. Thomas Somerville, M.A.
19th, Mon.—"Brunswick and its Museum." Mr. James Paton, F.L.S.
20th, Tues.—"A Trip to Norway" (*with costumes and music*). Mr. W. G. Tait.
21st, Wed.—"To Ober-Ammergau and Back in 1890." Mr. W. Lamond Howie.
22nd, Thurs.—"Mary, Queen of Scots." Mr. George Mason.
23rd, Fri.—"Days at the Coast." Mr. A. Lindsay Miller.
24th, Sat.—"Edinburgh in 1826" (*with music*). Rev. William Brownlie, M.A.
26th, Mon.—"Guernsey and Sark." Mr. Robert Walker.
27th, Tues.—"My Visit to the Holy Land." Mr. T. D. Stockdale.
28th, Wed.—"Dr. Johnson in Scotland." Mr. Thomas Rennie.
29th, Thurs.—"Past and Present." Mr. F. H. Newbery.
30th, Fri.—"Iceland." Professor Mavor.
Oct. 1st, Sat.—"The Gold and Diamond Fields of South Africa" (*with musical accompaniment*). Mr. D. S. Salmond.
3rd, Mon.—"Scotland." Dr. Colville.
4th, Tues.—"A Caravan Tour." Mr. T. N. Armstrong.
5th, Wed.—"Our Great Composers and their Local Surroundings" (*with musical accompaniment*). Mr. James Aitken.
6th, Thurs.—"Marvellous Melbourne." Professor Wallace.
7th, Fri.—"Fashion in Dress." Mr. James Muir.
8th, Sat.—"Landscape in Art." Mr. James Paterson, R.S.W.

It will be observed that the above programme embraces very many new subjects, and further, in several cases, included some special features not generally hitherto combined with limelight lecturing. This was specially noticeable in the Norway lecture, when not only a very interesting series of pictures were shown by Mr. Tait, but he also introduced some of the native costumes, and likewise, with the aid of his lady friends, gave the large audience examples of Norwegian songs and instrumental music. The fair lady friends, who appeared in costume, gave a peculiarly *piquant* and bright effect to the whole lecture, which was greatly appreciated by the large audience. Then, again, in the lecture on Our Great Musical Composers, the rendering of the various examples of our great masters was exquisitely given by a quartette party, who assisted Mr. Aitken in no small degree to make what would have otherwise been a bald lecture more than interesting by the introduction of such high-class music so perfectly rendered.

In numerous other instances, as will be seen from the programme, music formed a very interesting item, going as it did, hand in hand with good pictures and instructive information.

In compiling such a programme, extending over five weeks, and which embraced no less than twenty-eight different gentlemen as lecturers, only two of whom, it may be said, were not locally connected, the Council doubtless had some trouble in the way of overcoming numerous scruples on the part of those who were not provided with lantern transparencies to illustrate their lectures; but even this was not permitted to stand in

the way of the rendering of what was known to be a good subject, and in all cases where lantern slides were not on hand the Council at once set about providing such for the occasion, and it was only by such action that many of the interesting subjects were arranged. Nothing was permitted to stand in the way of the scheme being made attractive. To this bold step doubtless must be attributed much of the success in compiling such a varied and interesting programme.

In scrutinising the list of lectures, we find that, out of the total of thirty-three delivered, exactly twenty of them were specially got up for this Course—a proof, if any were needed, of the enthusiastic spirit which animated those who took the undertaking in hand. Specially noticeable among the list of new productions must be noticed *Sir Walter's Land*, by Mr. Napier, and *Mary Queen of Scots*, by Mr George Mason. These gentlemen for months past must have been occupied in personally visiting and photographing the many interesting places in connexion with their subjects. Mr. Mason has succeeded in putting together an entirely new set of pictures, very many of which, such as Queen Mary's relics, are of more than ordinary interest, not only to the antiquarian, but also to the general public—a collection which, indeed, it will be impossible to duplicate, hence its value. I have said that in many cases where the lecturers were not provided with lantern slides to illustrate a subject that it was known they were competent to handle well, the Council of the Institute provided such for them. In this action they not only acted liberally, but set a good and wholesome example to those who hold the stupid opinion that every lecturer ought to show only his own slides, or, at least, such from his own negatives. Were such an absurd doctrine to become invariably the rule, there would be an almost insuperable barrier raised to the production of some of the best subjects by the very best men.

True, in one or two cases, the audience were treated to the gratuitous information that all the pictures shown were taken by the speaker for the time being, but such information failed to elicit any expression of approval on the part of the audience, and perhaps in a few cases, had such individuals substituted professional slides for their amateurish productions, the result would have been better. The opinion in Glasgow is decidedly gaining ground that all lecturers should strive to obtain the very best slides to illustrate their subject, no matter who takes them be they professional or amateur, and when such comes to be generally, followed, the result will be apparent by a very much higher degree of excellence in the pictures thrown upon the screen, and an entire absence of the ludicrous sight too often witnessed of seeing a gelatine slide melt before the audience. Many gentlemen who are able scholars and lecturers are not conversant with slide-making, therefore why should they be debarred by such a ridiculous idea? Others, again, who are able slide-makers cannot utter ten sentences on a platform before they give way at the knees.

When the idea of organising such a lengthy programme was first mooted, there were not wanting plenty of quidnuncs who shook their pates, "It would never do," "Far too many lectures," "Public would get tired of it," and many other similar expressions of disapproval; but the public did not tire of it, and the attendance increased steadily till the end, when only one feeling was expressed, and that was one of regret that such an intellectual source of amusement was to close.

The limelight arrangements were of the most perfect kind, and in the hands of Mr. More not a single hitch occurred from first to last. Visitors were much puzzled to understand how Mr. More took his cue from the various lecturers so as to change each picture with such unerring precision, there being no sign or sound noticeable; and yet, at the exact moment, the desired change was made with the utmost certainty.

Some very funny opinions were expressed as to how this excellent mode of working was accomplished. One well-known face in photographic circles declared that Mr. More, for the time being, was an animated pincushion, and that by some means or other a needle was thrust into a fleshy part of his body when he was to change a slide. Others watched night after night in the fond hope of being able to solve the mystery. All were disappointed.

The method adopted is the joint invention of the subscriber and Mr. More, and is absolutely silent and certain in its action; in fact, being almost startlingly novel in its working when rapid changes have to be made.

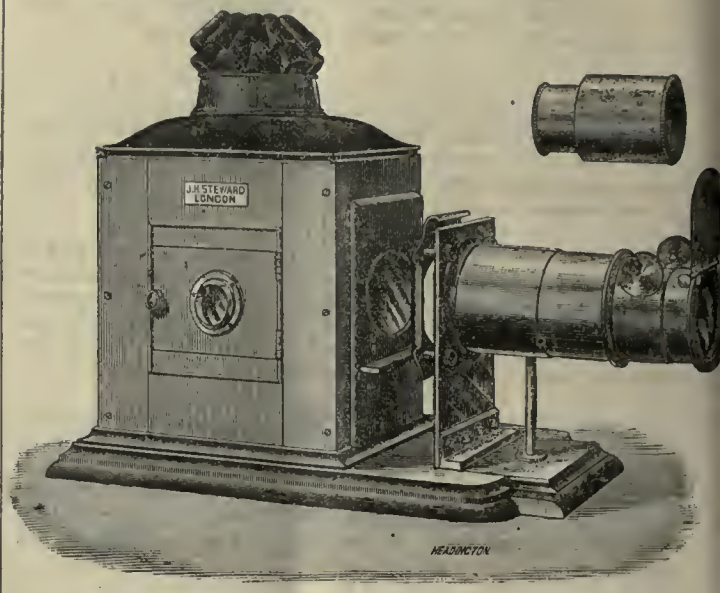
The ridiculous practice of using a crick-crick or castanet will never be seen in Glasgow again where first class lectures are given, and it is quite within the range of possibility, that before long the same action, which has now been introduced for the first time at these lectures, may be so extended as to permit of the lecturer actually changing his own pictures on the screen by the mere touch of a tiny button placed on the reading-desk.

It is more than likely that the Fine Art Institute will arrange for a similar course next year.

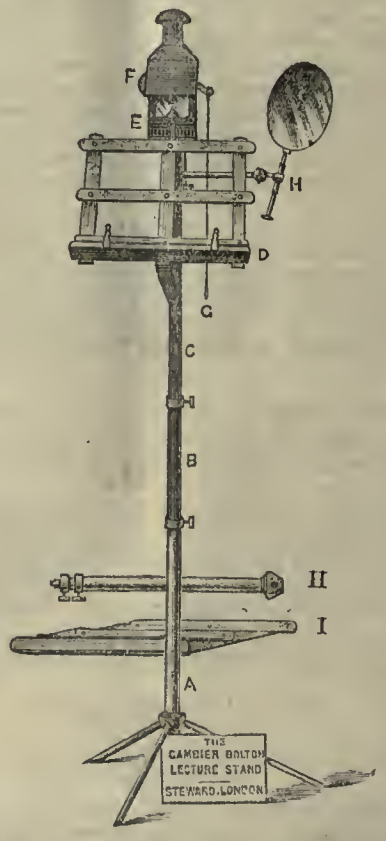
T. N. Armstrong.

SOME RECENT NOVELTIES IN LANTERN APPARATUS.

Concurrently with the commencement of the season, Mr. J. H. Steward, of 406 Strand, is introducing various novelties connected with the lantern and its accessories. Among these is a single lantern suitable for large halls, &c. Its distinguishing feature is that it is fitted with a solid tube



of large diameter, which is made a suitable length for the focus of the three-inch diameter lenses, with which the lantern is fitted, any further adjustmen being made by the rack and pinion jacket. If lenses of shorter focus are used, they are mounted complete in tubes of suitable length so that they push home to their focus.

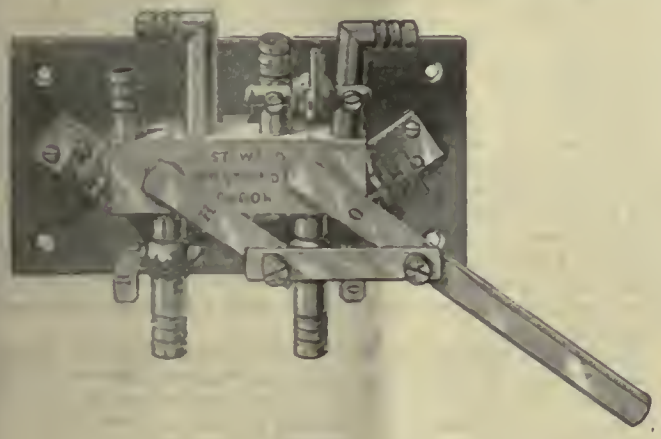


A bellows fronted lantern of the same firm has been designed to do all the regular work of an optical lantern for projection, and also to answer the purpose of a photographic enlarging lantern.

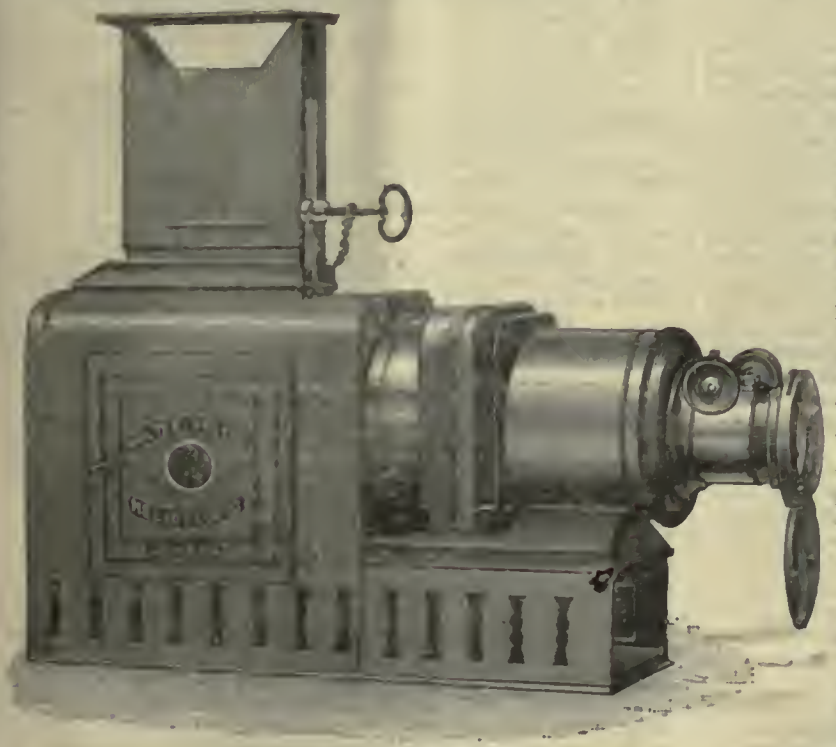
Mr. Steward is also introducing Mr. Gambier Bolton's portable lecturers' reading-desk, for enabling a lecturer to see the pictures shown on

the screen when his back is turned to it. The stand is composed of brass tubing made telescopic with clamps, and the three legs form a tripod at the base of this pillar, and pack inside the pillar for travelling. The mirror attachment, with ball and socket fittings, is to show the lecturer without turning his head what picture is on the screen. H shows the pillar closed up with the tripod legs inside; I shows the desk folded up.

In the "double plug" dissolver the gases pass through separate plugs from the supply pipes O and H, and then divide so as to conduct the gas to the two lanterns. The amount of bye-pass for the hydrogen flame is



regulated to a nicety by the screws and locking-nuts attached to the elbow-piece on the plate at the right and left of the plug-box, while a tap permits of the oxygen bye-pass being regulated if desired. The taps on the supply pipes can be partially or wholly turned off, and thus the apparatus or jets may be kept just burning or at once put out.



"The lantern season has commenced!" These were the words that sounded in our ears, issuing from the lips of Mr. Walter Tyler, on the occasion of a recent visit to his establishment in the Waterloo Bridge-road, London. Not only was this statement fully borne out by a cursory inspection of the activity which appeared to prevail among what may be termed the purely administrative sections of his business, but it received, perhaps, more cogent confirmation in other departments. Indeed, after a rapid inspection of the varied stock of lanterns and accessories, the famous lantern slide library, in which Mr. Tyler has gathered together possibly as large and diversified a collection of slides as are to be found in London or elsewhere; the stacks of gas bottles, charged and uncharged, the number of which the amateur, and maybe the professional lanternist, has no conception—in short, to witness the several branches of such a business as this in active operation, it is impossible to withhold the conviction, that whatever the fate of other divisions of photography may be during the present season, the section associated with the optica lantern is, especially at the present moment, undoubtedly in "full swing."

Among his latest novelties Mr. Tyler enumerates an electric lantern, such as, we believe, has been employed for projecting a picture of twenty-four feet in diameter on the drop-curtain of the recently opened Trafalgar Square Theatre. In appearance it resembles an ordinary single lantern, but it is asbestos lined, and the illuminant is an electric arc light. The focussing adjustment is actuated by a lever, which reaches from the objective to the rear of the lantern.

The features of the Helioscopic lantern, which, we gather, is in considerable request, are that it burns paraffin or any mineral oil, while the limelight can also be used with it. The body is of Russian iron, and it has solid brass fronts. It is fitted with Stock's lamp, and it is claimed that the objective employed is possessed of great flatness of field. Of the neatness and portability of the Helioscope there is no question.

Mr. Tyler showed us a very handsome single lantern intended for use in a neighbouring church, incidentally to which we had opportunities of observing to what an enormous extent the lantern figures in modern church work, by an inspection of his order-sheets for a couple of days. Undoubtedly a very respectable volume on the civilising influences of the optical lantern might be compiled.

Messrs. Archer & Sons, of Liverpool, are fitting their Ideal single lantern, which we noticed on the occasion of its introduction last year, with a new form of their Ideal dissolver. This is now made in a stronger form, while the fan is made to clear the lens a little more effectively.

OPTICAL PROJECTION.

[Royal Institution Lecture.]

The intention of this lecture is to give a general survey of the subject of Optical Projection, which now takes its position in science, and to present examples of what may be done by this method. It would be difficult to determine which subject claims a first place. Some scientists say the microscope should have the preference, while others take a different view. For my own part, I think the microscope and polariscope stand foremost, on account of the facility with which these branches of science may be pursued for the benefit of a large number, without multiplying expensive apparatus; also because of the convenience in saving the eyes from undue strain. Indeed, to many persons, looking at objects in the table microscope is little short of a painful operation, and consequently the study of small objects becomes to them impossible. The projection method immediately brings the required relief.

For general instruction, projection methods are invaluable, such as, for instance, showing diagrams, photographs, and other slides, upon the screen; as well as for spectrum analysis. In fact, the subjects which can be illustrated by means of optical projection are innumerable; but time will allow me to present only a few examples, and I trust that, when I approach the end of my lecture, my view of the importance of this subject will be held in equal estimation by you.

Probably the only people in the world that benefit by the experience of their predecessors are those who pursue the study of science. They are free from the accusation of robbing the brains of other men, when they take up methods or apparatus already known and improve upon them or employ them for their own work. In such cases, however, it is always understood that honour should be given where honour is due, and accordingly I have no wish to represent to you any piece of apparatus as of my own devising, which in reality belongs to another.

Few men have had a larger experience, and attained greater success in optical projection, than has Mr. Lewis Wright, who has embodied in his most recent forms of apparatus all that was good in designs existing unti

his time. I have, therefore, started from his models, making such modifications as I thought to be desirable. Mr. Wright does not appear —if I may say so—to have had much experience with the electric arc light as a radiant, and I found, at a very early stage, that great difficulties had to be encountered when this light was used, chiefly because the radiant approaches more nearly to what theory requires. That which was easy with the limelight became almost impossible with the arc lamp, and these difficulties had to be conquered.

Many scientific men are dissatisfied with the projection microscope, on the ground that very high magnification does not give that resolution and that sharpness which is found in the usual methods of observation. This want I fully admit. At the same time it is scarcely right to condemn a particular method because you try to apply it to an unsuitable purpose. Hundreds of thousands of subjects may be shown with the projection microscope with far greater profit to the student than was possible in the old way. The very fact that the professor can place his pointer upon any part of the picture on the screen is invaluable to the students. I shall, therefore, attempt to show you only a series of microscopical subjects suitable for projection, and shall not employ very high magnification.

In regard to some substances very high powers may be used with advantage, but much time would be lost in getting them into the field and focussing them upon the screen. These, consequently, I omit, so that a large number of subjects may be illustrated.

It is fair to state that most of the apparatus used to-night has been constructed by Messrs. Newton, of Fleet-street, and the luminous pointer by Messrs. Steward, of the Strand. The arc lamp is a Brockie's projector. Messrs. Baker, Watson, and others have also come to my assistance.

I will first show, on the screen, a picture of the lantern carrying its various apparatus; and then a few systems of lenses, which may be employed for the projection microscope, as well as a diagram of the microscope itself.

Sub-stage condensers and objectives are, as a rule, made to suit the table microscope. When projecting, by means of an objective alone, in consequence of the screen distance being very great—or, in other words, the microscope tube being exceedingly long as compared with the table instrument—the objective has to be approached very close to the slide; in fact, with the higher powers, closer than the cover-glass will allow. This close-working distance renders necessary special sub-stage condensers, and in many cases a special one is required for every screen distance with each objective. This requisite would seem to be a complete stumbling-block to microscope projection work. With the limelight the difficulties do not enter in the same degree as with the arc light, and as we are now dealing with the latter, further reference need not be made to the oxy-hydrogen light. There are two ways of surmounting the difficulty; one by the use of plano-concave lenses, introduced in such a way as to be equivalent to greatly lengthening the focus of the objective on the screen side, while it enables, as a consequence, the objective to be slightly further removed from the slide, *i.e.*, giving what is termed a greater working distance. The objection to this method is that, even when these plano-concave lenses are corrected, the result, though greatly improved, is not perfect. The second way, which is a perfect one, is that of introducing an eyepiece. In both these methods, that the best results may be obtained the objective is made to occupy a position not very different from that which it would do if employed on the table microscope.

In the eyepiece method almost the exact conditions can be complied with for which the objective was made. I propose, therefore, to show the subjects by the eyepiece method. The only objectives which will be used are: (1) Zeiss's 35 millimetre projection objective, the sub-stage condenser, 4 inches focal length, placed a considerable distance from the slide; (2) Newton's 1-inch projection objective, the sub-stage condenser as in the first case; and (3) Zeiss's ¼-inch achromatic objective, the sub-stage condenser being Professor Abbé's three-lens condenser with the front lens removed. In all three cases the eyepieces used are Zeiss Huyghen's No. 2 and No. 3.

In each instance I will mention the magnification in diameters, as well as the number of times when reckoned by area, for the appreciation of those who estimate by area; and I will also give the size to which a penny postage stamp would be increased, supposing it to be made of indiarubber, and stretchable to any extent in all directions. In presenting these figures I do not pretend that they are absolutely correct, but as they have been ascertained under conditions similar to those now existing the errors will not be very great.

In consequence of the field not being quite flat, and the sections having a certain thickness, although extremely thin in most cases, the whole of the object cannot be in focus upon the screen at the same time. By shifting the focussing screw slightly all parts may be brought into focus successively. So-called greater depth of focus is obtained by using an increased working distance; and for projection work over-correction for flatness can alone give a sharp picture all over with very considerable depth of focus; the difficulty of over-correction being that, unless extreme care is taken, certain forms of distortion may be introduced. By stopping down the objective greater flatness of field may be secured, but at the expense of light. There is thus a choice of difficulties, and the least one should be taken.

Turning now to the polariscope. Polarised light teaches us a great deal concerning the structure of matter; it is also a means of confirming the undulatory theory of light. This subject is so large that no attempt can be made to give even a general idea of the field it covers, and the experiments, which will be shown in the polariscope, may be taken simply as a few illustrations of the subject and nothing more; but they will, at any rate, be suggestive of the large field to which this method of analysis can be applied. A vast amount of mathematical proof can be illustrated graphically by various experiments with polarised light. I will show on the screen a diagram of the polariscope. (Shown.)

With reference to showing the spectrum. The method of projecting a spectrum, I think, is new, as I have not seen it described anywhere. It gives practically a direct spectrum with an ordinary prism, without turning the lantern round to an angle with the screen; and here is a diagram of the method.

The details of the apparatus, as well as those of the methods of working I have modified in almost every instance, for five reasons:—(1) That more certain results may be ensured; (2) that rapidity may be obtained; (3) that only one operator may be needed; (4) that, as far as possible, all parts of the apparatus may be interchangeable; and (5) that loose screws and pieces may be dispensed with.

There were then shown by projection a number of slides illustrating various microscopic optical systems, and a number of microscopic slides, followed by a series of general polariscopic projections, some of them to illustrate the strains existing in many forms of matter; also a spectrum by a carbon-disulphide prism, in conjunction with a reflecting prism and with a mirror, which, apart from any other result, demonstrates that the loss of light with a reflecting prism is less than with an ordinary glass mirror. Slides and other projections were also thrown upon the screen.

The details are as follows:—

The Microscope.—Screen distance, 21 feet. First 35 millimetres Zeiss projection objective, 4-inch sub-stage condenser, Zeiss Huyghen's eyepiece 2; 500 diameters = 250,000 times = penny stamp stretched to cover about 147 square yards. Subjects shown: proboscis of blowfly; permanent molar displacing milk-tooth (kitten); human scalp, vertical; human scalp, surface; fossil ammonites and belemnite. Second, 1-inch Newton projection objective, 4-inch sub-stage condenser, Zeiss Huyghen's eyepiece 2; 1000 diameters = 1,000,000 times = stamp stretched to about 588 square yards. Objects shown: proboscis of blowfly; foot of a caterpillar; section of human skin, showing the sweat ducts; phylloxera vastatrix of the vine. Third, 1-inch Newton's projection objective, 4-inch sub-stage condenser, Zeiss Huyghen's eyepiece 3; 1300 diameters = 1,690,000 times = stamp stretched to about one-fifth of an acre. Slides shown: proboscis of blowfly; wings of bee (showing hooklets and ridge); sting of bee (showing the two stings, sheath, and poison sack); sting of wasp (showing same as last slide); eye of beetle (showing the facets). Fourth, ¼-inch Zeiss's achromatic objective; Abbé's 3-lens sub-stage condenser, with top lens removed; Zeiss Huyghen's eyepiece 3; 4500 diameters = 20,250,000 times = stamp extended to nearly 2½ acres. Slides shown: proboscis of blowfly; hair of reindeer (showing cell structure); hair of Indian bat (showing the peculiar funnel-like structure); sting of bee (showing the barbs); foot of spider; stage of the micrometer (the closest lines ruled to thousandth of an inch, which measure 4½ inches apart under this magnification); a wave length $\frac{1}{40000}$-inch, therefore, on screen measures about $\frac{1}{9}$-inch.

The Polariscope.—Shown with parallel light; plain glass; glass under pressure; chilled glass (round, oval, and waved peripheries); Prince Rubert's drop (broken in the field); horn; selenites (over-lapped); butterfly (selenite); bunch of grapes (selenite); bi-quartz, with ¼-wave plate (the ¼-wave plate in this experiment produces the same effect upon the bi-quartz as if a column, 20 centimetres long, of a 7½ per cent. solution of cane sugar were placed between the polarising nicol and the bi-quartz (the analyser has to be rotated about 10°); a piece of sapphire to show asterism. Shown with convergent light; hemitrope (cut in a plane, not at right angles to the axis); ruby; topaz; grape sugar (diabetic); cane sugar; quartz; superposed right and left-handed quartz (spirals); calcite

and phenakite superposed (showing transition from negative to positive crystal, passing through the apopholite stage).

The Solidiscope.—New form of apparatus for showing solids, and consisting of two reflecting prisms and suitable projecting lenses. With this instrument were shown:—Barton's button, the works of a watch, a coin.

Spectrum Analysis.—Spectrum thrown by means of a disulphide prism combined with a reflective prism; the result being that a good spectrum is thrown upon the screen direct without turning the lantern. There were shown:—The spectrum; absorption bands of chlorophyll, &c.; effects produced by passing the light through coloured gelatine films.

Protection of Slides.—Decomposition of water; expansion of a wire by means of heat; combination of colours to form white light; various diagrams, coloured photographs of a workshop, &c. As an extra experiment there was shown, in the polariscope, with a convergent light, Mitscherlisch's experiment (illustrating the changes which take place in selenite under the influence of heat).

There are but few who would disagree with me in the opinion that the microscopic world, as regards its design and its molecular structure, is quite as wonderful as the great works around us seen with the unaided eye. A magnifying glass of low power opens up a world far larger than that which we are accustomed to see. At the present time, even with the most perfect apparatus that exists, only a small portion of the universe is known to us.

Scientific study should be pursued by all in a greater or less degree. It teaches more important lessons than the most impressive discourse ever preached. During the investigation of what is generally termed the invisible world, men should at times pause to reflect, and ask themselves such questions as these: What is the meaning of, and to what end is, creation? Is it all mere chance? Were such wonderful designs and properties created at the beginning? Was there in matter at the beginning an inherent, or implanted, power of development? Simple as these questions may seem, man in the flesh will never be able to find the true answers. The extraordinary design and structure which have existed in the unseen world for millions of years, or possibly in all past time, and even at the present day known to so few, demonstate at least that the great Power has bestowed the same care upon what appear to us the most insignificant portions of creation, as upon what we think are the greatest works in the universe. These silent sermons must surely influence the mind, and set it thinking of the supernatural and of our duties during life.

It may now with truth be said that science gives us means, such as never before existed, of appreciating the greatness of the Supreme Spirit, by enabling us to read fresh chapters in the book of nature.

SIR DAVID L. SALOMONS.

ADVANTAGES OF A NATIONAL LANTERN SOCIETY.

[*American Amateur Photographer.*]

In the workings of the American Lantern Slide Interchange there has developed a desire among amateurs not belonging to clubs to enjoy some of the advantages of the interchange, it being suggested that they have the privilege of paying a stipulated amount for the use of sets of slides; but, as the present interchange is a confederation of clubs, there is no provision for the use of its slides by individual amateurs.

We think if a lantern society, national in character, was organized, having certain centres for the storing of sets of slides, lanterns, and screens, arranged with suitably prepared lectures, that could be loaned for a moderate sum to members, a most interesting branch of photography would be popularised. It would enable many amateurs, who only wish to give lantern entertainments at long intervals, to secure the use of a first-class apparatus at a small sum, and avoid the expense necessary in purchasing a good lantern and its accompanying equipments. Such a society would have the best apparatus for oil or gas, and make a point to see that it was always in good order. In addition to the apparatus there would eventually be a fine varied collection of slides to draw upon, as it could be made a condition of membership that each member would be required to furnish a certain number of slides each year.

We shall be pleased to hear from our readers interested in slide work on this subject. We believe such a society would become very useful. A similar organization in London, "The Lantern Society of London," has sent to the American Lantern Slide Interchange one of the best sets of English slides ever seen here. There, members of the Society having sets of slides loan them to the Society for the use of other members, and are entitled to the use of other sets belonging to the Society. A member loaning a private collection of slides has the privilege of withdrawing it at any time from the Society by giving a month's notice. Members who do not contribute or donate slides to the Society are obliged to pay twelve cents for each dozen, or part of a dozen, they borrow for exhibition purposes, and fines are provided for in case a set of slides is kept beyond a certain time. The special object of the Society is to acquire suitable apparatus, for the purpose of giving exhibitions of general and scientific interest; to offer awards for the development of the optical lantern and apparatus pertaining thereto; to impart instruction in the use of the lantern and its apparatus; to secure for its members special advantages in the purchase and loan of apparatus and slides; to originate a large and comprehensive loan collection of lantern slides illustrative of art, science, and kindred subjects, such collection to be placed at the disposal of every member of the Society; to provide means of intercommunication between members for the promotion of the interchange of private collections of slides; to collect and impart to such members as desire it information as to the means of obtaining permission to photograph in the various public museums and collections.

Special branches of photographic work undoubtedly demand special organizations to thoroughly promote them, and for this reason a lantern society would appropriately meet the wants of those interested in slide-making and lantern work.

RECENT LANTERN PATENTS.

APPLICATIONS FOR PATENTS.

No. 19,121.—"Improvements in Optical Lanterns." A. J. JONES and S. J. LEVI.—*Dated October* 25, 1892.

No. 19,314.—"Improvements in Screens for Magic Lanterns or Optical lanterns." W. MARSHALL.—*Dated October* 27, 1892.

PATENT COMPLETED.

IMPROVEMENTS IN BOXES OR CASES FOR MAGIC LANTERNS.

No. 14,995. HERBERT CHARLES NEWTON, 3, Fleet-street, London, E.C. —*September* 24, 1892.

IT is usual for the makers of optical lanterns to provide a box or case in which the lantern can be transported from place to place, which case is employed as a stand for the lantern when in use.

The case has generally been arranged so that one or both sides should let down to act as a table on which to place the slides, the sides being supported by tapes or chains.

But this has been found inconvenient, as the table takes up too much space and prevents free access to the lantern, and the chains or tapes are in the way when exhibiting, besides which, if both sides are let down, the framework of case has to be stronger and heavier than is absolutely necessary.

It has also been found desirable to have a tilting-board, so that the lantern may be more or less tilted without moving and wedging up the case; but the addition of a tilting-board adds weight to the case, which is undesirable.

Now, the object of the present invention is so to construct a case for optical lanterns that the above requirements will be provided for, and, at the same time, the weight will be reduced to the minimum.

The claims are:—1. A box or case for optical lanterns, constructed and arranged substantially as described. 2. In a box or case for optical lanterns, adapting one side to form a shelf supported at or about half the height of the box in guides, and part of the other side to form a tilting-board, as described.

Exchange Column.

Wanted, lantern screen and stretcher about twelve feet, also mechanical slides in exchange for good burnisher and large printing frame.—Address, W. COLES, 60, Queen's-road, Watford.

Correspondence.

THE PURITY OF OXYGEN.

To the EDITOR.

SIR,—As an old subscriber and occasional contributor during the last thirty years, I beg to congratulate you on your enterprising movement, re "Lantern" issue in connexion with THE BRITISH JOURNAL OF PHOTOGRAPHY, and I feel sure it will be greatly appreciated by your numerous readers.

Now there is an important matter in connexion with the "Lantern" which I should like to place before your readers at the early part of the coming winter season, viz., the purity of oxygen as supplied by the different companies in cylinders, in comparison with home-made gas, by the process usually adopted with chlorate potash and manganese.

As an old hand, and much experience, I must say I rarely get so good a light with the gas supplied in cylinders as I do with the old method and gas bag, not that the bag has anything to do with it. I find that, if the gas is kept (cylinders), it rapidly deteriorates, and is little more than atmospheric air; if that is so, undoubtedly it will be the same if stored in the company's gasometers, which will account for the gas not being always of the same quality.

Last evening (as an instance), I used a twenty-foot cylinder of oxygen which had been used on two previous occasions, filled about two months ago; the light was very poor; this was nothing new, as I have experienced the same result before; there was plenty of pressure, and gases carefully adjusted; a six-foot bag was filled from the cylinder, after the use of it was over, before sending it to be refilled. I offer no explanation myself, but hope this communication will be the means of calling attention to the matter, and useful discussion be the result.

The above applies chiefly to the blow-through jet. As yet there are no reports of burst cylinders, I think, but as there is certainly a change takes place in the quality of the gas when kept long in the cylinder, may there not be a corrosive influence at work, which will eventually weaken the cylinder?

I was very sorry to see the report in "Lantern" issue of the retort accident, which the simplest of precautions would have prevented. Trusting the different companies will not think I am disparaging their gas, as I am only opening the matter for discussion, as an interesting subject.—I am, yours, &c., FREDERICK BAILEY.

October 26, 1892.

THE CHARITABLE LANTERN ENTERTAINMENT SOCIETY.

To the EDITOR.

SIR,—The above Society, the objects of which are to provide free lantern entertainments to charities and hospitals, has now been formed, and we shall be pleased to secure the names of gentlemen wishing to join.

We shall be grateful for any help, also gifts of any apparatus and sides.—We are, yours, &c., B. FOULKES WINKS, F. SIMMONS, } *Secretaries.*

Y. M. C. A., 182, *Aldersgate-street, E.C.*

Lantern Notes and Queries.

AMOS.—Yes; oxygen is "poisonous" in so far as by itself it will not support life.

T. R. P. (Kensington).—This correspondent asks us for particulars of the National Lantern Society. We never heard of such an organization.

F. BROMHEAD (Clifton).—Messrs. George Gill & Sons, of 13 Warwick Lane, E.C., are now the proprietors of Messrs. Mason & Payne's opaque lantern screens.

G. T. R.—The total elimination of the smell of oil lamps is difficult to accomplish. In Stock's and others, however, it is so minimised as to be not very noticeable.

THOS. B. WALSHE.—Our correspondent sends us a photograph of the remains of the oxygen retort which, as described by himself last month, exploded with such unpleasant consequences.

S. WALES.—Commander Gladstone, at the last meeting of the Lantern Society, exhibited a lantern of which several parts were constructed of aluminium. See a reference to the subject under *Lantern Notes and News.*

V. NIXON (Portsea).—Undoubtedly; there are lanterns in the market which can be used for either "optical projection or for enlarging." They are usually made with bellows fronts in order to serve the double purpose.

NOVICE (Herne Hill).—No; it is not our intention to inaugurate lantern-slide competitions in connexion with this SUPPLEMENT. Such and similar competitions fall more appropriately within the sphere of photographic societies.

A. WILLS (Colchester).—The principal objection to the use of a lens of the rapid doublet type as a lantern objective is that, working as it does at (for the purpose) the comparatively small aperture of *f*-8, it would cut off too much light.

HYDROGEN.—No, we do not think any very appreciable advantage accrues in practice from the use of pure hydrogen. Common house gas contains one or more hydro-carbons, upon which its power of illumination depends to a large extent.

E. C. RICH.—The Brin Company, we believe, submit their cylinders to a periodical test. Although we have not the exact data by us, this test implies a degree of pressure such as the cylinders are not likely to be subjected to when charged with oxygen for use.

J. E. RIDDALL says: "Kindly inform me, through the medium of your paper, as to whether a gas incandescent light would be suitable for an ordinary optical oil lantern, as limelight is too expensive and complicated."—Yes; but the flame should not be too large.

OPERATOR says: "Is a blow-through jet likely to work well with the oxygen tube recessed three-eighths of an inch? It is then above the hydrogen inlet. The hydrogen aperture is three-sixteenths of an inch."—We see no objection to such a form of blow-through jet.

BI-CONCAVE.—From the fact that the image on the screen is only critically sharp in the centre, while the remainder is slightly fuzzy, it is apparent that the lens suffers from roundness of field. This is not, as you seem to fancy, the same thing as inferior covering power.

W. RAYE.—The smell which you say is "insufferable" may possibly be obviated by attending to the directions given by Mr. Frank Howard at page 670 of the JOURNAL for October 14. That method is simply never to leave any oil in the reservoir or wicks when the lantern is not in use.

LANTERNA (Maldon, Essex).—The light given by Mr. E. J. Humphery's magnesio-oxygen lamp would scarcely be suitable for projection purposes; and clearly the enormous quantity of powder it would consume in the course of an hour or so puts it out of court on the score of expense.

QUESTIONER (Erith).—Any of the hand cameras extant will serve your purpose but procuring negatives for making lantern slides from; but if, to quote your question, you "want a hand camera which takes films of the size of lantern plates," then is that condition fulfilled in the "Frena" hand camera of Messrs. Beck, which takes films $3\frac{1}{4} \times 3\frac{1}{4}$.

JAMES SYME writes: "Is the aero-carbon light, which I saw mentioned several times in the BRITISH JOURNAL OF PHOTOGRAPHY last winter, being used as a lantern illuminant?"—We do not know, but from what we saw of it, and from the opinion generally expressed of it it is possible that it would form a good substitute for the limelight.

MONS. F. M. RICHARD, of Paris, who recently exhibited the *Photo-Jumelle* before the members of the London and Provincial Photographic Association, desires us to notice the circumstance that the Chairman of the meeting in question (Mr. W. E. Debenham) thought the size of the plates or films used in the *Photo Jumelle* (see page 684, BRITISH JOURNAL OF PHOTOGRAPHY for October 21) suitable for lantern slides. We herewith accede to M. Richard's request.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*December* 2, 1892.

THE LANTERN RECORD.

CONTENTS.

THE LANTERN IN PHOTOGRAPHIC DEMONSTRATIONS.

That the optical lantern commands a growing popularity among photographers is a trite enough phrase, which we should scarcely care to employ here, did it not enable us to contrast the extent of its uses in societies and among individuals for the projection of lantern slides of purely pictorial interest, with the comparative desuetude under which it rests for the purposes of conveying information of a more practical nature. It is true that as an illustrative aid much advantage is taken of the lantern, but this is chiefly in a subjective rather than an objective manner. In addition to its utility for entertainment purposes, it is, of course, often employed as a means of imparting information on photographic matters, although not so frequently as one might.

Many points of practical photographic interest about which a great deal is said at Society meetings might possibly be brought home more clearly and forcibly to an audience by being objectively shown in the lantern. No subject in photography is more discussed than the development of the photographic image in its various aspects. Those aspects—such, for example, as the appearances of over or under-exposure—might conceivably be illustrated in the lantern with especial advantage to beginners and young photographers, and, may be, to older ones, for it is universally admitted that a brief object lesson is infinitely more calculated to impart reliable knowledge to the student than a great deal of verbal exposition unaccompanied by a practical demonstration.

Development on the screen is an old experiment, but an always interesting one, and from its occasionally cropping up here and there among the Societies we can also conjecture that it is of an instructive kind. A correspondent writes us this week asking how the experiment is conducted, and, in the hope that the information may be of service to other beginners, we include it in this article. No operation is more easily managed. Upon the stage of the lantern a trough of suitable size is placed, having in contact with its side nearer to the illuminant, a sheet of non-actinic ruby glass, the effect of this being to project a red disc upon the screen. The previously exposed plate is then placed in the trough, the developing solution introduced therein, and the ruby glass withdrawn when development commences.

The conditions commonly laid down for the successful prosecution of the experiment are: (1), A chloride plate, inasmuch as one of bromide is usually too opaque; (2), correct exposure; (3), the ferrous-oxalate developer, which presents a non-actinic medium to the illuminant. Possibly, however, a selected thin bromide plate might serve, and other developers besides iron under suitable circumstances, be available. Hence, not merely the normal development and growth of the image, but the phenomena of under or over-exposure, surface fog, the control of different developers in various degrees of dilution over detail, density, and rapidity of development; the effect of bromide; the processes of fixing, reduction, and intensification; paper development, and other photographic operations, might be objectively demonstrated to large audiences in this way. It has also been suggested that the actual retouching of the negative should, by means of a suitable optical system, be shown on the screen. To this point, however, we may possibly advert on another occasion.

Considering the ease with which lantern slides may be made now, it is also permissible to suggest that this method may supersede the old plan of showing diagrams, &c., in illustration of a paper, and that in other respects the lantern may supplant the time-honoured blackboard in many emergencies where it is desired to instruct as well as to inform a photographic audience.

LANTERN NOTES AND NEWS.

Two months ago we stated that the lantern was to be employed at the new Trafalgar-square Theatre for projecting pictures upon a plain act-drop between the acts. It seems that the idea was put into use on Saturday evening last, but scarcely in the manner we had anticipated. A theatrical contemporary remarks that "the management presented a number of advertisements on a white sheet, which took the place of the ordinary curtain, but the marked disapproval with which this intrusion was received will, no doubt, result in its discontinuance. With the newspapers and the public hoardings at the service of advertisers, to say nothing of the programme of the Trafalgar-square Theatre, Mr. Levenston may be recommended to let the advertisement-curtain drop." The employment of the drop-curtain for the display of painted advertisements is a device that is tolerated in very small music halls, &c., in London and the country, a fact which may have induced the Trafalgar Square management to conceive the error that the audience of a first-class West-end place of amusement would put up with the same kind of thing. We are doubtful whether people want to do anything but gossip and look about them between the acts of a play, and we are therefore not over-confident that optical projections at the theatre are worth troubling about on the part of managers.

* * * * *

A paragraph recently appeared in one of the newspapers implying that the lantern industry is suffering from depression just now. Like other items of technical news which one reads in the daily press, it is not above suspicion on the score of reliability. During the last

few weeks we have had opportunities of learning from many of those concerned in the lantern trade that the state of business with them is of a satisfactory nature, a condition of things which, in all probability, is fairly typical of lanterniana just now.

* * * * *

A few weeks back a Committee was formed in one of the London parishes with the view of organizing suitable entertainments for the inmates of the local workhouse, and now we observe that the members of one of the South London Photographic Societies have commenced a series of lantern nights free to the public. To our thinking the one idea connects itself with the other. This and other Societies might now and then well get up an occasional lantern evening for the delectation of the poor people in the workhouses, and we throw out the hint in the hope that it will be taken advantage of. Such a kindly act, we are sure, would be welcomed in the right spirit by many Boards of Guardians.

* * * * *

Our readers will remember that about a year ago two gas explosions in connexion with the lantern occurred, one at Ilkeston and one at a well-known London photographic society. In the latter case it was thought by many that the explosion was due to the employment on the oxygen cylinder of a gauge into which oil had gained admission, and we were informed that in consequence of this it was resolved to discontinue the use of gauges and to purchase a balance. The balance was duly bought, but, if we are rightly advised, has never been used. In connexion with the use of gauges, it is interesting to note some remarks on the subject by Mr. C. F. Budenberg at a recent meeting of the Liverpool Amateur Association. That gentleman said that there was no occasion for the least risk of danger in the use of a gauge so long as the user took care to ascertain that he got a well-made article. He stated that, while inferior gauge-tubes were made out of ordinary drawn steel tubing roughly finished, the reliable instruments were made from pressed octagonal steel bars bored, and afterwards carefully turned, and polished inside and outside. By fixing one of each kind of instrument upon a pressure-pump, he showed that the first was strained and rendered unreliable by being submitted to the ordinary pressure, and would easily have burst if the pressure had been slightly increased; but the second, after a pressure of several tons, returned to its original position without showing a fraction of displacement. Mr. Budenberg then referred to explosions which had been caused by turning the full force of oxygen into a gauge in which traces of oil remained. The intense heat generated by the sudden rush of gas rapidly consumed the oil, and an explosion was the result. This action was shown by placing a piece of wood in a brass tube, which was attached to a cyliuder charged with air. When the valve was suddenly opened the rush of air ignited the wood. The best gauges, the lecturer explained, were now made with a check, to prevent this sudden inrush of gas, so that, even if they were charged with inflammable oil, an explosion could not result. The latter statement should go far to dispel whatever fears have grown up as to the assumed dangers in using pressure gauges.

* * * * *

The Hackney Society is apparently fated to have trouble left behind from its exhibitions. Last year the Judges had to take action with regard to certain remarks passed on them in a now extinct publication; this year there is talk of litigation over the withdrawal of a medal awarded for a certain set of lantern slides, which, although not supposed to have received an award before, are alleged to have previously obtained a medal elsewhere. Rumour also says that trouble is likely to occur in reference to the *bona fides* of a certain set of hand-camera pictures which were shewn.

LANTERN SLIDES IN COLLODION AND GELATINE.

A couple of years ago, had I been asked to express an opinion on the relative values of collodion and gelatine plates for lantern-slide purposes, I should have unhesitatingly given it in favour of the former, but the improvements made since then in commercial gelatine antern plates, as well, perhaps, as an increased amount of care in their use, have made the question a far more difficult one to solve in an off-hand manner. Undoubtedly collodion has some advantages, more especially in the direction of variety of tone and absolute clearness of lights; that is to say, these qualities are attainable with less trouble than is the case with gelatine, though nowadays, in moderately careful hands, the latter plates are little, if at all, behind their rivals in this respect, while their extra rapidity places them far in front.

Possibly, if contact printing were the invariable rule, the slower collodion plates would enjoy a greater popularity, for, even with artificial light, the average exposure necessary is not inconveniently long; but, even when quarter-plate negatives alone are employed, it very frequently happens that slight reduction of the image is essential in order to include just the right amount of subject to produce the best results. Then, except with daylight, and that of fairly good quality, the camera exposure becomes too protracted to render the collodion processes available for amateurs' use, as their work must generally be performed in the evening.

Much has been written on the weak points of gelatine for transparency-work and on the precautions to be taken in order to avoid them or to reduce them to a minimum; but many of the chief defects have already been removed by the manufacturers, who, by the introduction of special plates of a less rapid character than those intended for negative work, have been able to greatly improve their qualities for the work in question. The high temperature or other conditions requisite in the production of a highly sensitive emulsion being no longer necessary, it is easy to prepare films that will develop entirely free from the slight veil that too often marks even the best of rapid plates, and which, though quite immaterial in a negative, is out of place in a lantern slide. Greater care, too, in the prevention of the formation of insoluble salts of lime in the emulsion during its preparation, has now left the onus almost entirely on the user of the plates of turning out results scarcely, if at all, inferior in brilliancy and clearness to the best collodion work.

Still, some little extra care is expected at the hands of the producer of lantern slides if he hopes to emulate collodion results, but it is not of a very serious character. It consists chiefly, as in the preparation of the emulsion, in avoiding any treatment that may tend to precipitate lime salts from the water used in development and washing. The most obvious way out of the difficulty is to use nothing but distilled water—a plan, however, which, I fear, is impracticable in the great majority of cases, while it is almost equally hopeless, especially in large towns, to rely upon a constant supply of rain or soft water. Much may, however, be done in mitigating the trouble, even with the hardest water, by avoiding the conditions which chiefly lead to such precipitation. The water, for instance, used for the first washing of the plates after development, as well as for mixing the developer, may be artificially softened by any of the well-known methods, the simplest of which is to add a few drops of ammonia, and then allow the insoluble matters to subside; and if the softened water can be boiled after this treatment, or before subsidence, so much the better.

When ammonia, carbonate of soda, or potash, is added to a "hard" water containing lime or barium salts in solution, a precipitate is pretty certain to be formed, so that, in washing a plate after development with ordinary tap water, the alkali remaining in and on the film is calculated to produce this result, and, what is worse, the precipitate occurs *in* as well as on its surface. From the surface it may be removed by simple mechanical means, but it is not so easily got out of the gelatine again by the application of solvents, and this is an instance where prevention is decidedly better than cure. Citric and oxalic acids, too, tend towards the formation of insoluble compounds with both lime and barium, which are constantly present in hard water; therefore cleaning solutions containing these acids are to be avoided. Hydrochloric and nitric acids are free from this tendency, and should therefore be preferred, but it is better still to refrain altogether from the use of the ordinary clearing solutions containing alum.

Wherever sodium sulphite is employed, as it is in most modern developing formulæ, the image will be, or ought to be, free from stain, so that a clearing solution, in the ordinarily accepted meaning of the term, is unnecessary. But, as a safeguard against the formation of insoluble salts by the action of the spent developer, the plate should

be first of all immersed in water rendered very slightly acid with either hydrochloric or nitric acid; two or three minims of the ordinary commercial acid to each ounce of water will suffice to neutralise the alkali remaining without exercising any injurious action upon either the image or the gelatine film itself. After this treatment, boiled or softened water may be used with safety, or, if absolutely necessary, ordinary tap water; but in the last case the plate should pass through two or three changes of acidified water before final washing and fixing.

There is not much danger in the use of tap water after fixing, but before drying the film it should be carefully and gently rubbed with a well-moistened tuft of cotton wool, or, better still, with a pad of soft chamois leather thoroughly saturated. The latter forms a soft velvety rubber with which it is almost impossible to injure the gelatine surface, while it suffices to remove any sediment that may be mechanically attached to the film. A single trial of this plan upon a portion only of a plate developed in the ordinary way and washed with common tap water will show, after drying, how necessary the treatment is. Finally, after drying the transparency it should be warmed and again polished, this time with a perfectly dry pad of cotton wool or washleather lightly but firmly applied.

With these slight precautions, which take more time to describe than to carry out, the lights of a gelatine transparency will be as clear as those of the best collodion, provided, of course, the same care has been exercised in the preparation of the plates. It may be, however, that from some cause or another carelessness on the part of the plate-maker or of the user, that a slight veil still shows itself in or on the film, or such may arise from the gelatine itself being not perfectly transparent. Most of those who have ever practised emulsion-making will have noticed that with many samples of sheet gelatine there is a dusty appearance on the dry sheets which disappears when the gelatine is wetted but reappears on the dried film. The only remedy in such cases is to varnish the transparency, a practice which is tabooed by many operators, though I can see no valid reasons for their objection if the operation is carefully performed. The objection to varnishing seems to have taken its rise from the fact that, under certain conditions, the image on a gelatine plate—and for that matter on a collodion plate also—possesses a certain amount of relief which is further accentuated by the application of any of the ordinary quick-setting spirituous varnishes, with the result that a sort of ridge is formed wherever a shadow cuts sharply against a light, and consequently the definition is interfered with when the picture is thrown on the screen.

But this result only occurs in the case of a gelatine plate when its drying has been hastened by the application of heat or alcohol, and frequently in collodion plates, when the image has been developed or intensified with silver. Even then the evil only becomes appreciable when a thick varnish is employed, such as is necessary for the protection of a negative film. For the purpose of destroying the slight veil on a transparency we only require an extremely thin film of gum or resin, which acts in much the same manner upon the veil as oil or wax upon a paper negative, and any ordinary negative varnish of good quality, diluted three or four times with alcohol, will answer fairly well. But a plain solution of shellac is to be preferred, as giving a harder and more even coat. Bleached lac forms the lightest-coloured varnish, but it is liable, if not of good quality, when first dissolved to lose its transparency afterwards, for which reason a really good sample of orange lac is preferable, as, though its colour in solution may appear very dark, it is scarcely, if at all, noticeable on the glass. Another useful varnish is made by dissolving celluloid in acetate of amyl. These should not be applied until the transparency is perfectly dry, and in using the spirit varnish the plate should be thoroughly warmed—but not made hot, or ridges may be formed—and kept warm until the varnish has completely set or even dried.

Another useful varnish of an aqueous nature is made by boiling five parts of bleached lac and one part of borax in twenty parts of water until the lac is dissolved; the solution is then filtered and set aside for some days, until a fine sediment settles out of it and leaves it perfectly bright, when the clear portion is decanted for use. This is applied to the transparency by pouring it on to the latter on a levelling stand after drying, using a camel's-hair brush or a strip of paper to lead it over the surface. Allow it to soak for a few minutes, when the dry gelatine will absorb a certain quantity, and, after pouring off the surplus as closely as possible, further absorption will take place, and the surface of the film will assume a beautifully smooth and even appearance, which remains after it has become thoroughly dry. This varnish, after once drying, forms a perfect protection against moisture, but has a tendency to crack at a very high temperature.

A second aqueous solution consists simply of diluted albumen, but its preparation requires some little care. Take the white of an ordinary-sized egg, measuring, say, a fluid ounce, add six minims of strong ammonia, and stir well for two or three minutes. Then add gradually five ounces of distilled water, and mix the whole very thoroughly by vigorous *stirring*, not by beating or shaking. The result will be a rather cloudy solution containing a quantity of flocculent and stringy matter, which, however, is removed by filtration, leaving the liquid perfectly clear and bright. If the mixture be beaten or shaken, a part of the insoluble matter will be broken up into so fine a state of division as to pass through the filter and leave an opalescent solution, which is what we have to avoid. This is applied in the same manner as the preceding, and is free from the tendency to crack at a high temperature. It is needless to say that the transparency must be perfectly free from dust before applying the varnish, and must be protected until dry.

Collodion transparencies also suffer occasionally from a species of opalescence arising from a different cause, and differing from fog or veil arising from development. Unsuitable pyroxyline is to blame in this instance, the collodion, although perfectly transparent and bright, drying with a more or less opalescent appearance that detracts from the brightness of the image. This, like the opalescence arising from lime in the gelatine film, disappears when the image is wetted or varnished, and may be remedied by the application of any of the preparations already described. The two first are applied to the dry film with the same precautions as in the case of gelatine plates, and the remaining two are better applied before drying when the pores of the film are still open, by pouring on and off two or three times until the protective solution has thoroughly displaced the water remaining on the surface. The plate is then reared on edge to drain and dry.

If these simple precautions be attended to, not only will the lights of the transparencies produced approach more closely to the description of "clear glass," but there will be fewer complaints against the plates and their makers.

W. B. Bolton.

LANTERN MEMS.

Dissolving taps should be periodically tested, to see that the plugs have not worked loose, for defective dissolvers, either in construction or from working loose, are a far more common cause of pops than generally thought.

* * * * * *

On several occasions what was supposed to be faulty jets fitted to biunial lanterns turned out to be the failure of dissolver. If any doubt, reverse the connecting tubes from the dissolver, so that the supply is different. Then light up again and dissolve. If the plug is dry, the gas will sometimes find its way from one side to the other.

* * * * * *

If tubes are taken off at any time, bear in mind that, with the star shape six-way dissolvers, the opposite corner tubes *diagonally* are connected to the same jet. For instance, the top right-hand tube, say, for hydrogen, and bottom left for oxygen to the one jet, and bottom right-hand (Hy.) and top left-hand (Ox.) to the other jet. The central tube being the supply in each case, hydrogen on the right and oxygen on the left, or as marked on the taps of stopcocks on cross tubes or by-passes.

* * * * * *

Curtain shutters for rolling up effects are often made in one piece, and then not cut, so that there is a proper interval between the opening and bottom of shutter. The effect on the screen from this is that a *broad* interval of black (or white) shows between the curtain and picture, or between the one picture being rolled up and the other that is being revealed. This is obviated by having an adjusting slide to shorten or lengthen the interval mentioned according to the focus of objectives employed and the angle of the fronts.

In the higher class of biunial and triple lanterns, this arrangement, instead of being a strip of metal adjusting by slotted pieces and screw heads, is an entire supplemental slide, and is controlled from the top of shutter by a milled head adjusting screw. This same slide draws right up so as to reveal the entire opening in front of condenser and behind the slide in the stage, and thus permits of the curtain shutter remaining in the lantern all the time.

* * * * * *

Four-legged stands for lanterns are taking the place of three, and are much liked because they are firmer, do not spread out so far, and so do not occupy so much room as the tripod, besides which, are not so likely to be capsized from an accidental touch or kick. A steady stand for apparatus goes a long way towards the satisfactory exhibition of slides, for nothing is worse than pictures on the dance.

* * * * * *

Oxygen gas is to be produced by electricity from atmospheric air, and I hear that one firm, having an amount of power running to waste, contemplate putting gas so made on the market. The cost is mentioned at a remarkably small figure for production, but the transit in bulk to London and the larger cities and centres, as well as distribution in marketable quantities after the compression in cylinders, will represent the chief outlay; but, including all this, the price per cubic foot is computed at a lower figure than any oxygen gas at present supplied. As regards purity, it is supposed to be all that can be desired.

* * * * * *

If operators would label their cylinders they would not get astray as they sometimes now do; and besides, if a leather label is used, and a card marked each time the gas is used, and the duration of use stated, they will have a fair idea of the remaining contents without gauging.

* * * * * *

With the greater knowledge possessed now by pressure gauge makers, the absence of oil from fittings, safety checks, ventilating doors, &c., pressure gauges can be used without fear, and no operator need start an exhibition without knowing he has enough gas, especially as gauges can now be had from 15*s.* upwards, or scales used for weighing.

* * * * * *

I heard of an "old hand" operating the other evening for one of the popular lecturers of the day, and although questioned as to quantity of gas, and pooh-poohing the suggestion that there did not seem to be enough gas for the lecture (after setting up and trying lantern for discs, &c.) the light failed within half-a-dozen pictures of the conclusion of lecture.

* * * * * *

Automatic regulators are, to my mind, preferable without stop-cocks to the outlets, for, if too severe a strain is put upon the valves or bellows from any cause, the indiarubber connexion to the jet would give before the works or cover of regulator did. The number of regulators used during the past three years, and with so few failures, have established their success, and if treated with reasonable care should have a long life.

* * * * * *

The valves of gas cylinders should never be opened with a rush, and, if the screw is difficult to turn, call attention to the same when sending the cylinder to be refilled, and have it eased. If obliged to use a cylinder with very tight or jammed-up screw, don't make the gauge or regulator connexion gas-tight until the cylinder valve is opened a little. Then in case of a rush of gas, it will harmlessly escape around the connexions. The regulator or gauge can then be tightened up.

* * * * * *

The nut around screw valve of cylinder sometimes gets loose. It should be tightened up with a wrench on receiving it back from the compressor or optician, and periodically examined to see if it is quite tight by trying if the nut will screw up tighter.

G. R. Baker.

LANTERN SHOWS AT HOME.

There is no disputing that the exhibition of pictures by the aid of the optical lantern is not only one of the most amusing and interesting, but at the same time popular, methods of making an agreeable variation to the usual occupation of social gatherings—especially now that so many dabble in photography, and turn out work more or less creditable, so that they are able to bring back pictorial records of places they have visited, and by the aid of the optical lantern renew their acquaintance, to their own gratification and that of their friends. However, with the best intentions, many experience a difficulty in making the lantern projection the success it would be in skilled hands, even when supplied with the most irreproachable appliances; and it is to these that the following article may be of some assistance.

We will presume that the lantern and slides are good, the difficulty being to get satisfactory pictures on the screen. The usual faults are unevenness of lighting and definition, unsymmetrical forms, architectural subjects anything but upright, variations of the intensity of the light, badly burning wicks filling the room with smoke and blacks, with an offensive odour, and a general irregularity in the show anything but satisfactory to either audience or operator.

In getting up a lantern exhibition at a private house, the first consideration is the apartment to be used for it. The chief difference between a private and public show of this kind is the size of the image thrown on the screen, and consequently of the screen itself; also the distance from which it is viewed. We find when we do not use sufficient care in levelling a photographic camera the upright lines in the subject are distorted; the same rule holds good with the lantern, unless we have it and the surface on which the image is projected at right angles with each other, a similar distortion takes place. It is therefore a primary and invariable rule that the screen and projected picture must be at right angles with each other, or the parallelism of straight lines will be destroyed. The height of the lantern should be equal to the centre of the screen on which the pictures are thrown, and well clear of the heads of the audience. If much lower than the centre, the lantern must be inclined upwards, and the screen also tilted forward at top to correspond.

For a display in an ordinary dwelling-house, there is seldom much difficulty in fixing the lantern at a proper altitude. There are two methods of showing the pictures, one on an opaque screen and the other on a semi-transparent one. When the projections are of small size—say, not exceeding four feet—the latter method is much to be preferred, as the brilliancy of the picture is greatly enhanced, little or no light being absorbed by the screen. But, supposing we require a disc twelve feet or more in diameter, the opaque screen is best.

Now, about the room. The greater number of houses have two rooms separated by folding doors, which is an excellent arrangement for a lantern show through a semi-transparent screen. To utilise them, the doors must be thrown fully open, curtains draped artistically on each side—a valance at top improves the effect—and the centre part filled with a fine linen sheet stretched tightly, and free as possible from seams and defects; if joins are unavoidable, they should run horizontally in preference to vertically, as the sky shows the least markings, and by the horizontal arrangement the seams are in a great measure hidden by the subject, or at least but little noticeable. In lieu of a sheet, tracing paper stretched on a light frame forms an excellent screen. The chief drawback to its use is its liability to damage and its somewhat restricted size, for it is almost impossible to join tracing paper satisfactorily. Tracing paper at least four feet in width is readily procurable, and thus permits of a pretty-sized picture being thrown on it for an apartment of somewhat limited area. Setting aside the matter of size, the material possesses all the qualities required for a good semi-transparent screen.

A picture six or eight feet in diameter is sufficient for most home shows, and it may be borne in mind the smaller the picture the brighter the image; on this account the smaller image on the tracing paper screen more than makes up in brilliance and quality for the larger one seen on a reflecting surface.

Supposing we have to use a linen or other sheet, it must be carefully stretched and tacked over the doorway, beginning the tacking along the top and seeing that it hangs quite evenly, stretching the sheet gently from nail to nail. Now tack the two lower corners, then one side, the tacks being about six inches apart. In fastening the other side great care must be exercised not to stretch the material to form puckers and ridges, and it is probable that the two lower corners first fastened will now require a little attention; a few tacks along the floor will complete the screen. Wetting it all over with water, applied with a syringe or sponge, will improve the transparency and remove creases, and also increase the tautness of the strain, making it smooth as a drumhead. A bucket of clean water and a syringe may be kept in readiness, to wet the screen occasionally during the exhibition.

If only one large room is available, the sheet is best carefully hung at one end. Of course, transparency in this case is an objection, the whiter and more solid the appearance the better, so that as much light is reflected from it as possible. If the screen is buried, a portable frame is usually sent, to which it is attached by tapes, sewn at intervals along its edges.

In most private houses bare walls are unsuitable from a lanternist's point of view, when a room *can* be had with white-

washed for very pale-coloured walls, the necessity for any other screen is done away with, the walls themselves supplying the best of surfaces, absorbing a minimum amount of light. It goes without saying the surface should be free from any projection whatever, pegs, nails, or markings.

The screen being provided, the position of the lantern must be next attended to. It is best placed at a height about equal to the centre of the screen and carefully levelled, its distance from the screen determining the size of the picture, the nearer the screen the smaller the image, and *vice versâ*. Some lantern exhibitors alter the distance during the show if a transmitted picture is shown, and the apparatus small and handy; but a fixed position is nearly always best, and more convenient in every way. The lantern being placed, it is lighted up and the proper adjustments made between the condenser and the burner, so that a *clearly* illuminated disc is thrown on the screen. If we find that wavy, dark, crescent-shaped marks appear, it indicates that the light and screen are not in the proper place with regard to each other, or that the light is too large. The proper adjustment being effected, a test slide is inserted, and carefully focussed. This slide generally consists of printed matter covering the whole of the disc; the definition of the edges should be equal to the centre, which in printed matter is easily determined, more so than by any other kind of slide, although a good diatom slide runs it very close.

If it is an oil lamp, with several wicks, much depends on trimming them properly, both as to the quantity and quality of the light. There is considerable art required to properly trim a lamp; simple as it seems, it is a *sine quâ non* that the wicks should be accurately and smoothly trimmed; the least projection from them, as little bits of cotton not properly cut off, will make the lamp smoke, or the wicks, although level, being higher on one side than the other, will do the same thing if turned up to their full working height. It is a good plan to burn them a short time and then rub off the charred portion with a piece of soft paper, leaving no bits sticking about the burner. Any neglect in this respect will make itself apparent before the lantern has been long used by disagreeable odours, and probably a shower of blacks. The condenser will be dimmed, and the pictures restrained in brilliancy. In addition to the wicks receiving proper attention, all oil should be carefully wiped off the outside of the lamp, as when heated an unpleasant smell will be evolved. A good oil lantern properly attended to will give a more pleasant light for small pictures than the limelight, let alone the simplicity of working.

Compound gas in cylinders is certainly to be preferred if the screen is large and the lantern a considerable distance from it. There is, however, a certain amount of risk unless used with great care and circumspection, and by some one thoroughly acquainted with the management of the limelight. Accidents will occasionally happen with the most experienced, from circumstances that seem to be altogether beyond control, and therefore, for home displays, a good oil lamp is preferable, and will afford every satisfaction. It must be borne in mind that slides meant for use in an oil lantern must be thinner than if designed for the limelight, the penetration of the two lights being so very different; a slide that would be perfect in density for the limelight would be muddy and thick with an oil lamp, and *vice versâ*.

The lantern should be lighted a little time before the exhibition commences in order to warm it all equally, as in cold weather, when lantern shows are generally given, moisture will condense on the lens or condenser, and interfere with the display. This equalisation of temperature applies to the slides themselves, which, if placed cold in the lantern, will be almost obliterated on the screen by condensed moisture, which will take a little time to evaporate, not only spoiling the effect, but unpleasantly hindering the exhibition. The slides should be placed in a warm room, or before a fire, if they are brought out in a much cooler temperature than that they will be exhibited in, in order to prevent this.

To save trouble, all slides may be conveniently marked with two white spots on the top margin of the front, readily seen in the subdued light of the room, which at once indicates the proper way of inserting them in the lantern and prevents the mistake of showing a picture wrong side up or outwards without them having to perform that shining-up and twisting-about examination that often fails to answer the purpose. All slides to be shown are best arranged by daylight in their proper order and position, especially if a lecture or description is attached, to be read by some one unfamiliar with the slides themselves, or it may happen that a view of a cathedral, with a procession, may be described as a group of niggers on the beach, or something equally inappropriate.

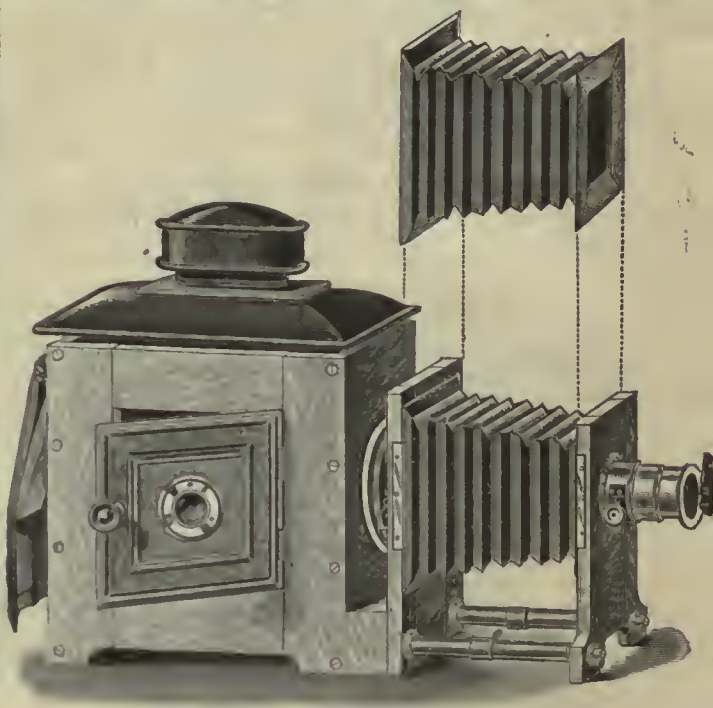
Music is a capital addition to any lantern show, and keeps the whole thing going as it were, and if the tunes chosen chime in, as it were, with the pictures, it adds considerably to the effect. In this connexion I would suggest that amateurs should spend a little time in stringing together a history of their slides, that they could read off during the exhibition. We have most of us heard with what difficulty the simplest description is often given when it has not been prepared beforehand. Many points are forgotten that would add considerable value if known; in fact, a very uninteresting picture pictorially might represent something of the most intense interest if we only knew, when we were looking at it, what it was.

EDWARD DUNMORE.

RECENT LANTERN NOVELTIES.

THE "LOTHIAN" OPTICAL LANTERN.

THIS lantern, which has been introduced by Mr. A. H. Baird, of 15 Lothian-street, Edinburgh, may be used for either oil or limelight. The body is made of polished mahogany, and the inside corners are iron-bound to prevent warping with heat. There are two panelled doors, with brass-bound, neutral-tinted sight holes, and a curtain behind to prevent stray light from affecting the eyes of the audience. The stage is open at



the top, and can accommodate any size or style of framed slide. The objective is mounted in a special jacket fitting, so that another lens o different focus can be inserted without unscrewing. The bellows front has a draw of from 5 to 14 inches, this varying length admitting of the use of an objective of any focal length. The bellows can be taken out as shown in the cut, to enable the lecturer to demonstrate in the lantern many experiments in physics which cannot well be seen under ordinary conditions by a large audience.

THE COMBINATION LANTERN SLIDE COVER GLASS AND SPOT BINDER.

MESSRS. W. BUTCHER & SON, of Blackheath, have introduced these cover glasses, upon which strips of binding are attached so that the slide may

be placed *in situ* and bound up quickly. The idea should be welcome to makers of lantern slides.

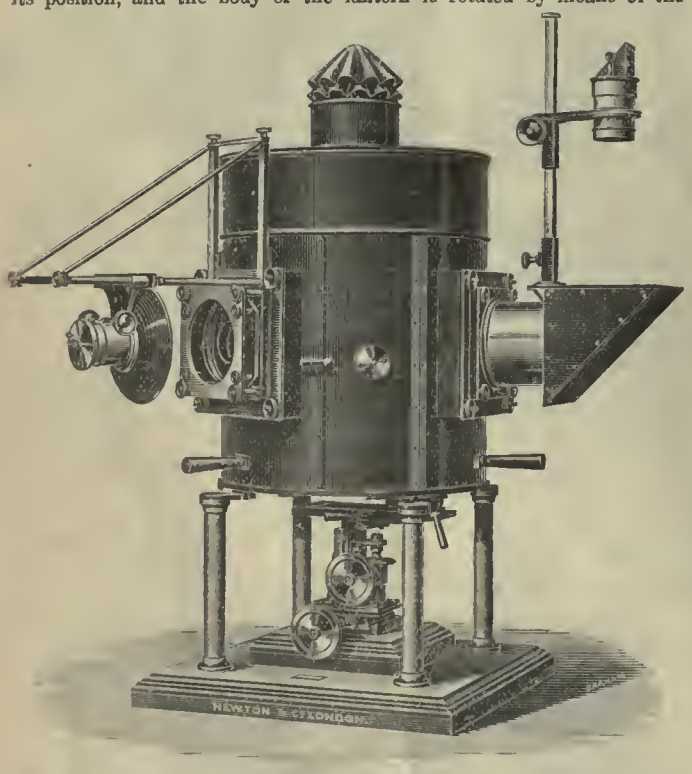
Mr. W. Tylar, of Waterloo-road, is issuing a lantern objective which is characterised by excellent flatness of field and covering power.

The Paget Prize Plate Company have two series of lantern plates on the market—the rapid, which give black tones with short exposures; and the slow, which give a variety of tones from black to red. We have tried the plates, and find them to give admirable results. The display of slides which the Company had on view at the recent Hackney Exhibition was of remarkable excellence as regards clearness, brilliancy, and diversity of tone. A new printing-out lantern plate is among the Company's imminent novelties.

Messrs. Newton & Co., of 3, Fleet-street, have just issued a new catalogue of science lanterns, magic lanterns, dissolving-view apparatus, and lantern slides. In its pages are contained illustrated descriptions of numerous single oil lanterns, limelight lanterns, biunials and triples, microscope attachments, and the numerous accessories of the ordinary lantern, while a section of the work is devoted to science lanterns pure and simple, with projection apparatus, microscopes, polariscopes, &c., for scientific demonstrations. Among these are included triple rotating electric lanterns; and in the work will also be found lists of objects for the polariscope, and a large and comprehensive general list of paintings, views, and figure subjects. The catalogue, with two supplements, is a complete guide to purchasers of lantern apparatus, from the simplest to the most up-to-date scientific kinds.

A Triple Rotating Electric Lantern.

We have had the opportunity of inspecting one of these lanterns, which are a speciality of Messrs. Newton & Co. As will be seen, the body of the lantern is cylindrical, and it is mounted on four brass pillars and mahogany stand. It can be arranged for use with any arc lamp. The base is fitted with a traversing table, which has screw motions travelling in gun-metal dovetails. This admits of the arc light being centred and kept absolutely central during use. The traversing table is made of polished gun-metal and steel, and steady motions in every direction are obtained by the large milled heads. The arc light is kept in its position, and the body of the lantern is rotated by means of the



handles bringing each front in turn opposite the fixed light, thus obviating the necessity of constant adjustments, and enabling any front to be used at a moment's notice without delay or trouble. A check action is provided to ensure exact centreing. The lantern body is furnished with three doors and sight holes, so that whichever optical system may be in use, there is always a door immediately behind the lamp, and a dark-glass sight hole in front, through which the arc may be observed. There are three fronts, each carrying an optical system, placed at angles of 120 degrees to each other, and the rotating movement brings up each as desired in front of the fixed light. One of these fronts is fitted with a 4½ in. double condenser for parallel beam work, and with diaphragm and slit fronts. A second front carries also a 4½ in. condenser with slide stage and double achromatic objective for exhibiting ordinary slides and diagrams. Either of these fronts will carry, if desired, a polariscope, a Wright's optical front, a small parallel-beam nozzle, or a vertical attachment. The third front is fitted with an electric microscope and micro-polariscope. All the fronts are detachable and interchangeable. The lantern can be used for the lime as well as the electric light. We understand that this form of lantern is in considerable use by scientific institutions, for which it seems eminently well adapted. In perfection and completeness of detail it is undoubtedly a fine instrument.

THE REFLECTOR WITH THE PROJECTION MICROSCOPE.

[*Nature.*]

The lantern is now used for so many purposes—scientific, photographic, and recreative—that any improvement in its construction will be acceptable. When we look into this instrument whilst at work, we must be disappointed at the large quantity of light lost by reflection and by dispersion—light which ought to go to the illumination of the screen. In the ordinary form of the lantern, three lenses of dense glass are employed as condensers. Each of these six surfaces reflects and scatters the light, and the glass itself is absorbent of its rays.

The dioptric construction of the projection lantern has been well worked out by Messrs. Wright, Newton, Salomons, and others, but the catoptric principle, which would eliminate almost entirely these disadvantages, has been scarcely at all studied.

Although my experiments have been made solely with the limelight in various forms, the following remarks may equally apply to light given by the electric arc:—

If a reflector be used instead of the ordinary condensers, it is obvious that the position of the lime cylinder must be reversed. This will present no difficulty, for the tube holding the jet can be bent into a helical form. The dark image of the lime cylinder also will have no more practical disadvantage than is experienced by a like image formed by the small plane speculum of the Newtonian telescope.

As to the mirror itself, although a parabolic form is the most correct, a spherical surface will be sufficient for mere illuminating purposes, and thus expense may be spared in the grinding of the more difficult curve. A speculum of from five to seven inches diameter, having a radial curvation of from two and a half to three inches, will grasp a large quantity of light, much more than that obtainable from the five-inch condenser usually employed.

Silver deposited by one of the various reducing processes on the surface of a clear glass lens will have many advantages over a metal mirror. The front surface will give perhaps the finest definition, but by silvering the back part of a spherical glass film, or that of a ground lens, the brilliant surface will remain untarnished for an indefinite time, and the whitish bloom formed by slow volatilisation of the incandescent lime is easily removed. This silver film adheres with remarkable tenacity, and it will bear a great deal of heat without blistering or becoming detached.

I have had considerable success in constructing such mirrors from the large ornamental glass spheres blown in Germany, and silvered within by Liebig's process, viz., with milk, sugar, and ammonio-nitrate of silver. A glass sphere of ten or eleven inches in diameter may be easily cut into eight or nine mirrors by a red-hot iron, and this without disturbing the silvering, which will require only gentle friction with a pad of cotton impregnated with a trifle of rouge to brighten it. Thus, at the cost of a few shillings, eight or more mirrors can be made, and also provision be made against possible accidents of cracking by heat.

The light radiant is so placed that the secondary focus is intercepted by a plano-concave lens of dense glass, as has been happily proposed by Mr. L. Wright. The convergent rays from the speculum are thus made into a parallel beam, which must be deprived of its heat by an alum trough, for the light and heat at the substage condenser is very great.

Convergence, I find, is usefully promoted by a plano-convex lens of about eight inches focus, placed two or three inches before the above-noted plano-concave lens. In all other respects the arrangements are like those of the usual modern projection microscope.

I have pretty constantly used the ether-oxygen saturator, and I consider it to be perfectly safe, if ordinary precautions be taken. The oxygen, compressed in cylinders, is much recommended, as there can be no mixture of vapour, except at the right place. The U-shaped horizontal saturator, plugged with flannel, must be well charged with ether, or with the best gasolene, and care should be taken, before beginning or ending an exhibition, to shut off the oxygen tap before closing the ether tap. This will prevent the harmless "snap" from the mixture in the small chamber at the joining of the gas tubes. If a disc more than eight feet be required for the microscope, it will be well to use hydrogen gas instead of ether, since the calibre of the jet cannot in the ether light very well exceed one-fourteenth of an inch.

As an extra security, I pack the mixing chamber with asbestos fibre, moistened with glycerine; but, as before urged, the oxygen must leave the saturator, saturated.

To ensure the coincidence of the foci of the reflector with the optical axis of the microscope, it will be well to place three adjusting screws in a triangle behind the mirror, and this last may have both a small vertical and horizontal movement.

I claim for this catoptric arrangement a larger grasp of light than can be got from ordinary lenses, and this may be effected also at a small outlay. For the amateur constructor the plan will afford many advantages.

G. B. BUCKTON.

SMALL PRISMS FOR LIMELIGHT POLARISCOPES.

[Stereoscopic Club.]

My object this evening is to demonstrate how far the lantern microscope can be depended upon for exhibiting the phenomena of polarised light.

The maximum size objects provided for the ordinary polariscope reach up to one and three-quarter inches, and for these an aperture of about three inches has been considered necessary, and Nicol prisms, or substitutes for them, having similar internal dimensions, were generally recommend.

began to be realised that this was a fact, and at the present day small analysing prisms are adopted in *all* polariscopes.

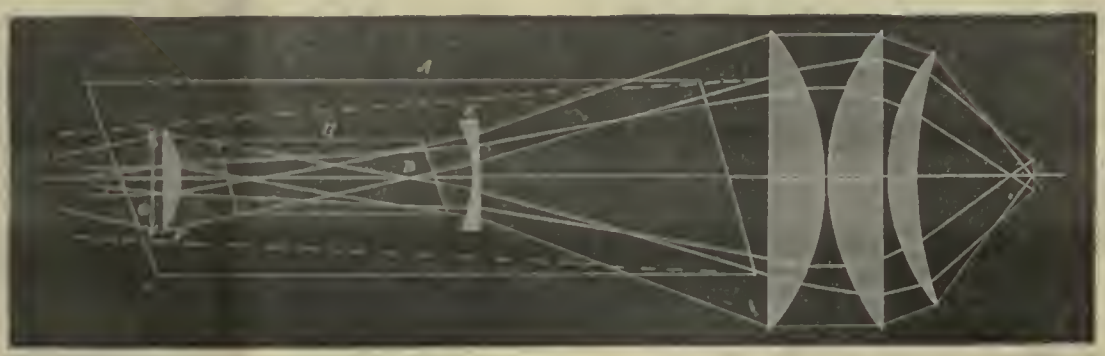
Well, I think the time has arrived for us *to begin to think* that large polarising prisms are just as useless in proportion as large analysers have been found to be, for then we shall the sooner *begin to realise the fact.*

However desirable larger blocks of Iceland spar may be, either as a commercial article or for prisms, or anything else, we know that the natural supply of the mineral has become practically exhausted, and even now a one-inch prism is a precious article. So, as it is a maxim in philosophy that if we cannot bring things up to our mind we must carry our mind down to the level of things as they are, I can console myself by showing that a prism of one-inch field will exhibit the maximum size objects sufficiently well to answer every practicable purpose.

Of course, I shall be fully prepared for some opposition from prejudiced individuals and others commercially interested. Changing from a large to a small prism for analyser was but a small affair, involving no slight alterations in the construction of the instruments, that nothing was affected except the reduced price of the prism; but when it can be shown that with a small lantern microscope having suitable prisms of, say, one-inch or one-and-a-quarter-inch field results can be produced to equal those obtained by the most elaborate instruments, costing 30*l.* to 100*l.*, the case is somewhat different.

Independent of its own cost, a large prism determines in the main the style and cost of the whole instrument, and, as I have said, this large size and elaboration is totally unnecessary, a sheer waste of money and of no benefit to any one but those who are commercially interested.

With the elbow polariscope, a large field is indispensable. The glass plate forming the polariser must be from four to five inches long, by reason of the polarising angle. A less size would not cover the one-and-three-quarter-inch objects, and on account of its form and size, it must of necessity be ungainly in use. I may here refer to a circumstance which occurred the other day as an illustration of this.



A. Large prism with three-inch field.
B. Small prism with one-inch field.
C. Rays passing through large prism.
D. Rays passing through small prism.
E. Concave lens, diminishing the vergency of the rays so as to pass them in the greatest quantity through the prism.
F. Sub-condenser concentrating the rays upon G, the object.

Of course, prisms having only two inches, and even so small as one and a half inch, field have been used, but it has been supposed that these small sizes could not show the maximum size objects. With the lantern microscope, prisms of only three-quarter-inch field have been supplied, but these were intended only for showing microscopic objects, and the instrument as a polariscope was not intended to be used for larger objects.

Let us now inquire if the large size, such as three inches, is at all necessary.

Some very reliable authorities have assured me that they are not, and that prisms of one-and-a-half-inch field are quite sufficient; and now I go a step further, and maintain that, with a one-and-a-quarter, or even a one-inch field, all that is needed can be done. With this small size the loss of light is very appreciable, and the dimension covered is very little less than with the three-inch prism, *if used in the right way.*

In days gone by it was customary to use large prisms, not only for polarisers, but also for analysers. I can remember a friend of mine who possessed a three-inch Nicol polariser expressing his regret that he had not also a three-inch analyser, as the one he was then using had only a two-inch field. Soon after this, however, *it began to be thought* that an analyser of half-inch field gave just about as good results as others of the largest dimensions. As time passed on, *it*

A well-known scientist of Manchester, possessing one of these elbow polariscopes, took it to an optician to be fitted to a new lantern. "No," said the optician; "do not use this obsolete instrument, but let us take the analyser out of it and use it as a polariser." This was done, and as the prism had a full one-inch field, better results were obtained by it, and an analyser of half-inch field, than had ever been obtained, or could ever be obtained, by the elbow polariscope in any way.

The appended diagram, drawn to scale, shows the rival prisms and their arrangement.

The rays pass convergently through the large prism, and do not require a sub-condenser before passing through large objects; but with a small prism a sub-condenser is required because so many rays leave it divergently. A large lantern condenser is not required with the large prism, as nearly all the rays outside the three-inch field are cut off or do not enter the prism. It cannot be used further than shown from the condenser, as that would cause the converging cone to be too small to fill the object, or to enter the objective in the best conditions for evenly illuminating the screen.

Some writers represent the concave lens E as passing the rays through the small prism in lines parallel with its sides, and accordingly call the lens a "parallelising" lens; but, having field lenses of all foci from nine to twenty-two inches, and found none which, wherever

placed or however used, were capable of passing the rays in any such like manner through the prism, I consider the designation misleading, and I do not use it. I do not even pretend that I have correctly represented the rays just as they pass through the lenses and the prism, but the diagram gives a sufficiently accurate idea of the path of the beam to show how it is to be managed when an object has to be illuminated which is larger than the field of the prism, and if the beam is properly managed there is not much to choose at between the illumination obtained by the different prisms, nor the size of objects that may be covered by them.

With the small crystals used in the polariscope, whether uni-axial or bi-axial, shown either by narrow angle or very wide-angle rays, there is no reason why the smaller polarising prism should not bear the palm, seeing that the crystals are so small, and require every advantage in the arrangement for transmitting rays through a very small aperture.

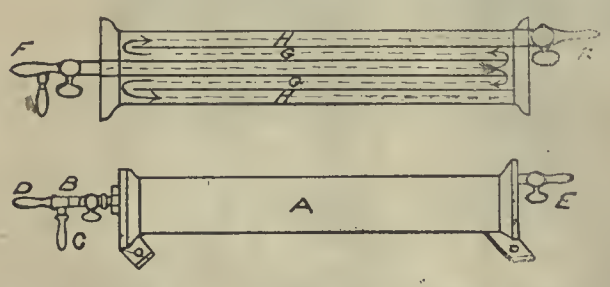
By using a Nicol polariser in the way I have advocated some precaution must be taken against injury to it by transmitted heat, and an alum trough or a water trough does this most effectively. The concave lens undoubtedly affords some protection to the prism, but it may be said to show how small is its effect that I know of three Nicol prisms that have been ruined by heat passing through them where the alum or water trough has inadvertently been omitted. In one of these cases the balsam was blown up into bubbles, and in the other two cases the ends were "frosted" so as to require repolishing.

I confess that a Nicol prism, large or small, is a delicate thing to use in a lantern; it is also costly, whatever be its size. Then those who prefer something less expensive may use polarising bundles (glass plates) with transmitted light, and when placed in the posterior part of the microscope and used just in the same way as the prism, very good results may be obtained by them. I have not unfrequently during an exhibition substituted a bundle for a Nicol, with so little alteration in the result that only an expert could have discovered the difference. Still, the prism gives the most beautiful results, which, for richness and splendour of colour, surpasses everything else in the range of optical science. W. Leach.

A NEW ETHER SATURATOR.

A firm in business at Melbourne, Australia, have just placed on the market a patent saturator for ether that is a great advance on any apparatus yet introduced, being exceedingly well got up, portable, and comprises a three-way saturation in the one tube.

It has been used for many public entertainments with complete success, the light being simply perfect, and quite free from snapping and hissing, troubles with which all users of the ether light are, unfortunately, only too conversant. This is attributed to the perfect saturation of the oxygen gas.



With two barrels so many troubles occurred that the inventors tried what benefit would accrue from the addition of a third barrel, and were gratified at the wonderful success of the extra saturation of the gas; but the apparatus was bulky, so further thought was given to the subject, the outcome being the single barrel with triple saturators. It will be difficult to improve on this.

The following will explain the drawing:—A is a brass tube, fifteen inches long by three and a half. B is the inlet pipe, D connects with bag or cylinder, C to oxygen tap of jet, E delivery tap of saturated gas connecting with H lap of jet. The oxygen from bag or cylinder enters the saturator at F, passes to the bottom of the tube and returns by G, and finally down the outside compartment H to the tap K.

E. Purton.

PEARS' MAGIC LANTERN.

On behalf of Mr. Henry Glave, draper, of Oxford-street, W., Mr. Warmington, Q.C., applied, on October 14, to Mr. Justice Kekewich, in the Chancery Division of the High Court, for an injunction to restrain Messrs. Pears from exhibiting on their premises, opposite those of the plaintiff, magic-lantern pictures or other devices so as to cause crowds to collect and obstruct the highway in front of plaintiff's premises, and to prevent the access of plaintiff's customers to his shop. The learned counsel put in a series of affidavits showing that for some time defendants had exhibited during the evening, from about six to nine or ten o'clock, a series of pictures, some of them movable, from their windows, leading to the assemblage of crowds who filled the pavements and highway, and blocked the approach to plaintiff's shop, besides causing him annoyance by their cheering at intervals and general noise. Sir R. Webster, Q.C. (with him Mr. Renshaw, Q.C.), appearing for the defendants, said they had used these pictures for some four or five years. There was no evidence of crowds until recently, nor was complaint made until search-lights were turned on to obliterate the pictures. As the case would have to be tried, he was willing, on behalf of the defendants, to give an undertaking (which he understood plaintiff's counsel was willing to accept) to exhibit only one picture, instead of a series, until the plaintiff's shop was shut, leaving the movable pictures, which it seemed, sometimes moved the risible faculties of the spectators, till the latter part of the evening, the costs of this motion being costs in the action, which must be left to be tried. Mr. Justice Kekewich said that was a fair offer. Of the law in the case he had no doubt, but the question to be decided was one of fact.

Lantern Queries.

W. Trimmer.—The suggestion to substitute petroleum ether for sulphuric ether in the saturator emanated, we believe, from Mr. F. E. Ives.

St. Elmo (Bath).—We do not know what you mean by "lantern shield," unless it be a species of shield, attached to a jet, for exposing only a part of the lime to the light. Such shields, no doubt, can be obtained to order, but we do not think they are much used. Heat the lime gradually, and the necessity for them disappears.

Doubtful.—Yes; a photograph on paper, if mounted between two glasses, can, at a push, be utilised for projection purposes.

P. Allen (Brixton).—The warm tones you admire may be produced by using a slow lantern plate, giving long exposure, and developing with pyro and ammonium carbonate.

W. R. Cornell writes, suggesting the employment of the optical lantern for projecting *negatives of line* subjects, such as plans, &c., where an enlarged copy is required, which could then be traced by hand.

A. French.—We cannot say if it is the invariable custom of competition lantern slides to be judged on the screen. If it is, then some of the judges at recent exhibitions have held offices which have been no sinecures.

W. M. Fitt (Hanley).—We cannot accept the task you are anxious to impose upon us. Doubtless by looking through the catalogues of the various lantern dealers you may be able to light on particulars of a "complete lantern fit-up for a guinea or so for exhibition purposes."

Jet.—The blow-through form of jet is probably more used than any other, and is on the whole the simplest for a beginner to employ with compressed gases.

R. Fenner.—Several lanterns are, we believe, fitted with a simple piece of mechanism for enabling the lime to be turned without opening the lantern.

Querist.—Oxygen is said to vary in illuminating power according to the method of its preparation: thus many believe the gas made from potash chlorate to be superior to other kinds.

B. Sc. (London).—Possibly Mr. Lewis Wright's book on *Optical Projection* would be useful to you in affording hints as to the employment of the lantern for projection in scientific experiments.

L. Simpson asks: "As I have an oil lantern, and am also a beginner in the black art, would you please tell me how I should proceed to show dry plate development on a screen. Can it be done so as not to fog the plate?"—See article on first page of the Supplement.

LANTERN FIXTURES.

December 5. Richmond Camera Club.
,, 6. Hackney Photographic Society.—Members' Lantern Night.
,, 13. Hackney Photographic Society.—*Print-out Lantern Plates, &c.*, Mr. Walter E. Woodbury.
,, 15. London and Provincial Photographic Association.
,, 15. Oxford Photographic Society.
,, 19. Croydon Camera Club.
,, 20. Hackney Photographic Society.—*Colouring Lantern Slides*, Mr. S. J. Beckett.
,, 21. Manchester Photographic Society.
,, 28. Photographic Club.

Mr. F. V. A. Lloyd, of 5, South John-street, Liverpool, has sent us his catalogue of lantern requisites and slides, of which it contains useful particulars.
